Abstract In the current research, catalytic effectiveness of synchrotron and synchrocyclotron radiations on Osmium Dioxide (OsO₂) and Osmium Tetroxide (OsO₄) nano capsules delivery in DNA/RNA of cancer cells is investigated. The calculation of thickness and optical constants of Osmium Dioxide (OsO₂) and Osmium Tetroxide (OsO₄) catalytic effectiveness of synchrotron and synchrocyclotron radiations on Osmium Dioxide (OsO₂) and Osmium Tetroxide (OsO₄) nano capsules delivery in DNA/RNA of cancer cells produced using sol–gel method over glassy medium through a single reflection spectrum is presented. To obtain an appropriate fit for reflection spectrum, the classic Drude–Lorentz model for parametric di–electric function is used. The best fitting parameters are determined to simulate the reflection spectrum using Lovenberg–Marquardt optimization method. The simulated reflectivity from the derived optical constants and thickness are in good agreement with experimental results.
1. Introduction

Catalytic effectiveness of synchrotron and synchrocyclotron radiations on Osmium Dioxide (OsO₂) and Osmium Tetroxide (OsO₄) nano capsules delivery in DNA/RNA of cancer cells is investigated. Osmium Dioxide (OsO₂) and Osmium Tetroxide (OsO₄) is a semi–conductor of type n which its 3d level is filling up [1-67] and it belongs to a group of smart materials that reacts to variations of temperature, electrical or magnetic fields and pressure. This oxide can be used as thin films for a wide range of applications including electrical and or optical–thermal switching tools and energy storing covers [67 -103]. Therefore, determining optical constants (refractive coefficient, n, and extinction coefficient, k) of Osmium Dioxide (OsO₂) and Osmium Tetroxide (OsO₄) nano capsules delivery in DNA/RNA of cancer cells with mole ratio of 0.5, 1 and 1.5% of Osmium Dioxide (OsO₂) and Osmium Tetroxide (OsO₄) is needed for parameters of dielectric function and the available results in the thickness which is defined as a range regarding physical condition [258- 313]. To do this, an initial guess of real and imaginary dielectric function according to its optical model should be selected and used for estimation extinction coefficient, k. for any thin layer, an appropriate optical parameters, various physical models such as Kuschi, Frouhi–Blumber and Tawk–Lorentz have been suggested to calculate refractive coefficient, n, and extinction coefficient, k. for any thin layer, an appropriate model should be selected and used for estimation of real and imaginary dielectric function according to its physical condition [258-313]. To do this, an initial guess is needed for parameters of dielectric function and thickness which is defined as a range regarding physical characteristics of thin film and the available results in the literature. Osmium Dioxide (OsO₂) and Osmium Tetroxide (OsO₄)–catalytic effectiveness of synchrotron and synchrocyclotron radiations on Osmium Dioxide (OsO₂) and Osmium Tetroxide (OsO₄) nano capsules delivery in DNA/RNA of cancer cells are produced over glassy medium in sol–gel laboratory, Faculty of Chemistry, BioSpectroscopy Core Research Laboratory and Cancer Research Institute (CRI) at California South University, Irvine, California, USA, under similar conditions. Measurement of thin films are performed on four samples of Osmium Dioxide (OsO₂) and Osmium Tetroxide (OsO₄) as catalytic effectiveness of synchrotron and synchrocyclotron radiations on Osmium Dioxide (OsO₂) and Osmium Tetroxide (OsO₄) nano capsules delivery in DNA/RNA of cancer cells with mole ratio of 0.5, 1 and 1.5% of Osmium Dioxide (OsO₂) and Osmium Tetroxide (OsO₄) [314-578]. Simulation of experimental spectra are performed using a single reflection spectrum of thin films and through Drude–Lorentz physical model in optimization process of Lovenberg-Marquardt. Optical constants such as reflection coefficient, n, extinction coefficient, k, and layer thickness are simultaneously determined at wavelength of 400–1100 (nm).

2. Modeling, Simulation and Calculation Method

A usual method for describing optical constants of thin films is utilizing classic dispersion relationships based on di-electric function. One of the oldest and most applicable dispersion relationships is Drude-Lorentz di-electric equation which is based on the interaction between light and material. This relationship is shown in Eq. (1):

\[
\varepsilon = \varepsilon_\infty + \sum_{j=1}^{n} \frac{f_j E_{0j}^2}{E_{0j}^2 - E^2 + i\Gamma_j E} + \frac{E_P^2}{E^2 + i\epsilon_i E}
\]

where \(\varepsilon_\infty\), \(f_j\), \(E_0\) and \(\Gamma_1\) are di–electric constant at high frequencies, resonance amplitude, power and resonance width–band which are recognized as the reason for damping. Damping is due to absorption process which includes transition between two states. The third term is related to Drude model. \(E_p\) is density of Plasma energy and \(E_i\) is incident energy [4]. The complex di–electric function as \(\varepsilon = \varepsilon_1 + i \varepsilon_2\) which describes the reaction of material with electromagnetic waves as a function of photon energy, \(E\), or wavelength, \(\lambda\), has a real part \(\varepsilon_1\) and an imaginary part \(\varepsilon_2\). Real and imaginary parts of complex reflection coefficient, namely \(n(\lambda)\) and \(k(\lambda)\) are related to di–electric function as Eq. (2) [5]:

\[
n(\lambda) = \left(\frac{\varepsilon_1 + \left(\varepsilon_1^2 + \varepsilon_2^2\right)^{1/2}}{2}\right)^{1/2}
\]

\[
k(\lambda) = \left(\frac{-\varepsilon_1 + \left(\varepsilon_1^2 + \varepsilon_2^2\right)^{1/2}}{2}\right)^{1/2}
\]

Reflection spectrum (R) of samples for normal incident is a function of film thickness \(d\), medium reflection coefficient \(S\), incident light wavelength \(\lambda\), reflection coefficient \(n(\lambda)\) and extinction coefficient \(k(\lambda)\). Simulation of the measured reflection data using optimization of objective function, which is the square of difference between the measured reflection spectrum and the calculated one, is defined as:

\[
O = (\varepsilon_\infty, f, \Gamma, E_0, E_P, E_i, d) = \sum (R_{meas} - R_{calc})^2
\]
where, \( R_{\text{meas}} \) and \( R_{\text{calc}} \) are the measured and theoretical reflection spectrum, respectively. Using the fitting parameters obtained from minimization of objective function, dispersion curves of reflection and extinction coefficients can be estimated.

3. Results and Discussion

The measured and simulated reflection spectra with fitting parameters of Osmium Dioxide (OsO\(_2\)) and Osmium Tetroxide (OsO\(_4\))–catalytic effectiveness of synchrotron and synchrocyclotron radiations on Osmium Dioxide (OsO\(_2\)) and Osmium Tetroxide (OsO\(_4\)) nano capsules delivery in DNA/RNA of cancer cells at various concentrations of 0.5, 1 and 1.5\%, named as a, b, and c, and catalytic effectiveness of synchrotron and synchrocyclotron radiations on Osmium Dioxide (OsO\(_2\)) and Osmium Tetroxide (OsO\(_4\)) nano capsules delivery in DNA/RNA of cancer cells sample, named as p, are shown in Figure 1 in wavelength range of 400-1100 (nm) (visible regions close to infrared) using Drude-Lorentz model for air, film, medium, air system.

![Figure 1](image1.png)

**Figure 1.** Results of simulating the reflection spectrum for Osmium Dioxide (OsO\(_2\)) and Osmium Tetroxide (OsO\(_4\))–catalytic effectiveness of synchrotron and synchrocyclotron radiations on Osmium Dioxide (OsO\(_2\)) and Osmium Tetroxide (OsO\(_4\)) nano capsules delivery in DNA/RNA of cancer cells at concentrations of (a) 0.5\%, (b) 1\%, (c) 1.5\% and (p) non–doped.

Comparison of the results were shown that the sample containing 0.5\% of Os (sample a) has shown more reflectivity than samples containing 1\% and 1.5\% of Osmium Dioxide (OsO\(_2\)) and Osmium Tetroxide (OsO\(_4\)) (samples b and c). As can be seen in Figure (1), the reflection of thin films is decreased by increase in mole concentration of Os to Osmium Dioxide (OsO\(_2\)) and Osmium Tetroxide (OsO\(_4\)). This reduction can be attributed to various reasons such as increasing roughness, increasing thickness and increasing the concentration of contaminant. The results of investigation about surface roughness using AFM method confirms the increasing of roughness by increasing the concentration of Os. Therefore, dispersion of incident light is increased in thin films. Variation of thickness of thin film by increasing the percentage of Os is effective in variation of reflectivity of thin films which is due to sol viscosity. Changing the crystalline structure and chemical composition of thin films induced by penetration of Os ions into the crystalline lattice of Osmium Dioxide (OsO\(_2\)) and Osmium Tetroxide (OsO\(_4\)) is another effective factor which leads to changing the reflection spectrum. The results of structural analysis using XRD confirms the tendency to be amorphous by increasing the concentration of contaminant.

The best fitting parameters obtained from optimization process and experimental data fitting are listed in Table 1.

![Table 1](image2.png)

**Table 1.** Fitting parameters of di–electric function of DL model

As can be seen in Table 1, more increase in Os leads to increase in \( \Gamma, f, E_0 \) and \( d \) and decrease in other parameters as crystalline structure and inter–atom distance changes in lattice of Osmium Dioxide (OsO\(_2\)) and Osmium Tetroxide (OsO\(_4\)) thin film. According to [7], \( E_0 \) in the range of 2.9-3.1 (eV) shows optical transition capacity band to displaced state of conducting band which according to the data of Table 1, it can be concluded that optical transition energy (gaff energy) increases with increase in Os concentration. The calculation results of optical constants including reflection coefficient and extinction coefficient using the parameters of obtained di–electric function from the optimization process of thin films at various concentrations of Osmium Dioxide (OsO\(_2\)) and Osmium Tetroxide (OsO\(_4\)) as 0.5\% (sample a), 1\% (sample b) and 1.5\% (sample c) are shown in Figure 2 and Figure 3, respectively.

![Figure 2](image3.png)

**Figure 2.** Reflection coefficient of Osmium Dioxide (OsO\(_2\)) and Osmium Tetroxide (OsO\(_4\)) thin films with Os concentrations of (a) 0.5\%, (b) 1\%, (c) 1.5\% and (p) pure sample.
As can be seen in Figure 2, reflection coefficient of samples at 500–1100 (nm) are the same and are decreased by increasing wavelength. By increasing the concentration of Os, reflection coefficient is totally reduced which is in good agreement with the results related to variations of reflectivity in Figure 1 in which, increasing roughness leads to increase in dispersion and hence, reducing the amount of reflection spectrum. It can be seen in Figure 3 that $k(\lambda)$ for two samples of p and a are of increasing rate at wavelength range of 400-500 (nm). Further, all samples are of decreasing rate at the range of 500-800 (nm). Totally, $k(\lambda)$ is reduced by increase in Os concentration. In other words, optical absorption is reduced in this range and the emerged peaks at extinction coefficient are in agreement with parameters of Drude–Lorentz obtained from the optimization algorithm.

4. Conclusions, Summary, Recommendations, Perspectives, Useful Suggestions and Future Studies

The results of optimization algorithm of Lovenberg–Marquardt with physical model of Drude–Lorentz for determining optical constants of Osmium Dioxide (OsO$_2$) and Osmium Tetroxide (OsO$_4$) catalytic effectiveness of synchrotron and synchrocyclotron radiations on Osmium Dioxide (OsO$_2$) and Osmium Tetroxide (OsO$_4$) nano capsules delivery in DNA/RNA of cancer cells produced using sol–gel method through a single reflection spectrum show that higher doping leads to lower reflectivity and reflection coefficient and also, leads to increase in thickness of thin layer.
