Abstract

Objective: To analyze the mortality associated with ethnicity, particularly of Indigenous peoples, in a large sample of patients with COVID-19 in Mexico.

Design: National, cross-sectional study.

Setting: Mexico.

Participants: 416546 adult patients; 4178 Indigenous peoples with COVID-19 were the primary population under study.

Main outcome measures: The primary outcome was mortality from COVID-19 up to August 3rd, 2020. Logistic regression was used to calculate odds ratios while adjusting for confounders.

Results: Among all patients with COVID-19, whether hospitalized or not, a higher proportion of Indigenous peoples died compared to non-Indigenous people (16.5% vs 11.1%, respectively). Among hospitalized patients, a higher proportion of Indigenous peoples died (37.1%) compared to non-Indigenous peoples (36.3%). Deaths outside the hospital were also higher among Indigenous peoples (3.7% vs 1.7%). A higher proportion of Indigenous peoples died in both the private and public health care sectors. The adjusted odds ratio for COVID-19 mortality among Indigenous peoples with COVID-19 was 1.13 (95% confidence interval 1.03 to 1.24). The adjusted odds ratio for COVID-19 mortality among Indigenous peoples with COVID-19 was higher among those who received only ambulatory care (1.55, 95% confidence interval 1.24 to 1.92).
Conclusions: In the large sample of patients with COVID-19, the findings suggest that Indigenous peoples in Mexico have a higher risk of death from COVID-19, especially outside the hospital. These findings suggest Indigenous peoples lack access to care more so than non-Indigenous people during the COVID-19 pandemic in Mexico. More research is needed regarding the impact of the COVID-19 among racial and ethnic minorities in Mexico.

Keywords: COVID-19; Indigenous health; ethnicity; mortality; Mexico

Introduction

As COVID-19 cases and deaths continue to increase around the world, an increasing amount of evidence shows that the current pandemic is disproportionately affecting socially disadvantaged groups. Several studies have demonstrated that older individuals and people with underlying medical conditions have an increased risk for adverse outcomes, including death. (1, 2) Moreover, emerging evidence from the USA, the UK, and Brazil has shown that racial and ethnic minorities (REM) have a higher risk of adverse outcomes and death from COVID-19 as well. (3–5) These health disparities may be due to a higher prevalence of underlying comorbidities and poor access to high quality health care services among REM. Furthermore, specific public health preventive measures to address COVID-19 are hard to implement in REM communities that live in densely populated areas, work on essential services, and use public transportation. (6)

Mexico has some of the highest numbers of confirmed cases and deaths in the world. As of August 5th, Mexico ranks seventh worldwide in total number of cases
and third in total number of deaths. (7) Access to testing has been a challenge in Mexico, which has one of the lowest testing rates worldwide. (8) Therefore, the true number of cases and deaths is probably higher. Similar to studies conducted in other settings, Mexicans who are older and who have an underlying medical comorbidity have a higher risk of adverse outcomes and death. (9–11) Mexico is a racially and ethnically diverse country, with an indigenous population of over 12 million (10.1% of the total population). (12) For centuries, indigenous peoples in Mexico have been marginalized and unfairly treated, resulting in unjust health inequities and unequitable access to health care.

The Epidemiological Surveillance System of Viral Respiratory Diseases of the Mexican Ministry of Health (MoH) collects sociodemographic and clinical data of diagnosed COVID-19 cases, across both public and private hospitals. These data are updated daily and are openly available to anyone. In this study, we aimed to analyze the relationship between risk factors, mainly ethnicity, and COVID-19 adverse outcomes (hospitalization and ICU admission) and mortality. The impact of COVID-19 on indigenous health needs be analyzed to address the existing health inequities that persist in Mexico. Furthermore, our results could help local, state, and federal governments identify high-risk groups for severe illness and death and help them with the implementation of specific preventive measures in these socioeconomically disadvantaged groups.

Methods

Study design and population
The present cross-sectional study is based on national and open access data reported by the MoH. These data set is published through the Epidemiological Surveillance System for Viral Respiratory Diseases (SISVER) and it includes data on all suspected COVID-19 patients who were tested for SARS-CoV-2. For this study, we included data from laboratory-confirmed patients with COVID-19 in Mexico from February 28 to August 3rd, 2020. The SISVER reports laboratory-confirmed cases through 475 Viral Respiratory Diseases Monitoring Units (USMERs) across the country, which consist of both public and private providers in primary care and hospitals. Patient information is collected by physicians based on an epidemiological study format for all suspected cases of COVID-19. Laboratory-confirmed cases were defined as a positive result of real-time reverse transcriptase-polymerase chain reaction (RT-PCR) assay.

A total of 443813 laboratory-confirmed COVID-19 cases were included in the SISVER data set. We excluded 11312 patients who were 17 years or younger, 12562 patients whose ethnicity was not recorded and another 3393 patients with missing or unknown data for type of health care sector (public or private) in which they were treated for COVID-19. The total sample for our study consisted of 416546 patients. We further divided our sample by hospital admission, resulting in two samples of 113853 hospitalized patients and 302693 non-hospitalized patients. Missing or unknown data on comorbidities and risk factors were treated as negative for that comorbidity or risk factor as they were most likely left blank on the form if the patient did not have it or did not know they had it. The variables included in our study were sociodemographic characteristics (age, gender, ethnicity, and
health care sector), comorbidities (diabetes, chronic obstructive pulmonary
disease, high blood pressure, and chronic kidney disease), risk factors (obesity
and smoking status), and adverse outcomes (hospital admission, ICU admission,
endotracheal intubation, and death). Ethnicity was assessed by asking if the
patient spoke any indigenous language, regardless of whether they also spoke
Spanish or not. These data are openly available at https://coronavirus.gob.mx/.

Statistical analysis

Continuous variables were described using the mean and standard deviation.
Categorical variables were described in frequencies and percentages. We
estimated odds ratios (ORs) with 95% confidence intervals (95%CIs) and their
Corresponding p-values for death by sociodemographic characteristics,
comorbidities and risk factors. A multiple logistic regression model was used
adjusting by age, gender, and health care sector for each of the comorbidities and
risk factors previously mentioned. The selection of variables for our model was
based on a review of the literature. All statistical analysis was performed using R
version 4.0.2 and RStudio Desktop version 1.3.1073.

Patient and Public Involvement

For this study, patients or the public were not involved in the design, conduct,
reporting or dissemination plans of our research.

Results

The MoH COVID-19 database included 1011050 suspected cases of COVID-19 as
of August 3rd, 2020. Of these, 432501 adult patients tested positive for COVID-19.
A total of 12562 had missing data on their ethnicity and 3393 had missing data on the type of health care sector (private or public) where they received treatment. In the end, our sample consisted of 416546 adult patients with COVID-19 (see Figure 1). Of these, 113853 required hospitalization (hospitalized sample) and 302693 received only ambulatory care (non-hospitalized sample).

Table 1 shows the demographic, comorbidity, and risk factor data among survivors and non-survivors in all three of our samples. Across all samples, the mean age of non-survivors was similar (61.0 in non-hospitalized patients and 62.0 in hospitalized patients) and higher than survivors. Among survivors, the mean age of hospitalized patients was higher than non-hospitalized patients (53.6 and 41.8, respectively). Across all samples, a higher proportion of men, Indigenous peoples and patients treated in the public sector died. A higher proportion of patients with chronic kidney disease (CKD) and chronic obstructive pulmonary disease (COPD) died inside or outside the hospital. The most common comorbidities in all patients with COVID-19 that resulted in death were high blood pressure (20383) and diabetes (17660). Among hospitalized patients, more than 40% of them with any of the four comorbidities analyzed died.

### Table 1. Sociodemographic characteristics and present comorbidities and risk factors among survivors and non-survivors of all COVID-19 patients, hospitalized patients and non-hospitalized patients.

|                              | All COVID-19 patients (n=416546) | Hospitalized patients (n=113853) | Non-hospitalized patients (n=302693) |
|------------------------------|----------------------------------|----------------------------------|-------------------------------------|
| Age (years ± SD)             | Survivors n=370038 (88.8%)       | Non-survivors n=46,508 (11.2%)   | Survivors n=72566 (63.7%)           | Non-survivors n=41287 (36.3%)       |
|                              | 44.1 ± 14.7                      | 61.9 ± 13.8                      | 53.6 ± 15.0                         | 62.0 ± 13.8                          |
|                              | 41.8 ± 13.6                      | 61.0 ± 14.1                      |                                    |
| Gender                       | Women (n=195153)                 | Men (n=221393)                   |                                    |
|                              | 178795 (91.6%)                   | 191243 (86.4%)                   | 16358 (8.4%)                        | 30150 (13.6%)                       |
|                              | 29357 (66.8%)                    | 43299 (61.8%)                    | 14588 (33.2%)                       | 26999 (38.2%)                       |
|                              | 149438 (98.8%)                   | 148034 (97.7%)                   | 1770 (1.2%)                         | 3451 (2.3%)                         |
| Ethnic group                 | Non-indigenous (n=412368)        | Indigenous (n=4178)              |                                    |
|                              | 336551 (88.9%)                   | 3467 (83.5%)                     |                                    |
|                              | 45817 (11.1%)                    | 691 (16.5%)                      |                                    |
|                              | 71559 (63.7%)                    | 1007 (62.9%)                     |                                    |
|                              | 40692 (36.3%)                    | 595 (37.1%)                      |                                    |
|                              | 294992 (98.3%)                   | 2480 (96.3%)                     | 5125 (1.7%)                         |
|                              | 1770 (1.2%)                      | 96 (3.7%)                        |                                    |
| Sector                       | Private (n=11476)                | Public (n=405070)                |                                    |
|                              | 10911 (95.1%)                    | 359127 (88.7%)                   |                                    |
|                              | 565 (4.9%)                       | 45943 (11.3%)                    |                                    |
|                              | 2579 (84.2%)                     | 69987 (63.2%)                    |                                    |
|                              | 485 (15.8%)                      | 40802 (36.8%)                    |                                    |
|                              | 8332 (99.0%)                     | 289140 (98.3%)                   | 80 (1.0%)                           |
| Comorbidities                |                                  |                                  |                                    |

Table 1. Sociodemographic characteristics and present comorbidities and risk factors among survivors and non-survivors of all COVID-19 patients, hospitalized patients and non-hospitalized patients.
Table 2 shows admissions to hospitals, ICUs, and deaths among Indigenous peoples and non-Indigenous people. A total of 4178 (1.0%) of patients with COVID-19 were Indigenous. Of these, a total of 1602 (38.3%) were admitted to the hospital compared to only 27.2% of non-Indigenous people. Additionally, 155 (3.7%) Indigenous peoples were admitted to the ICU compared to only 2.1% of non-Indigenous people. Regarding deaths (outside and inside a hospital), 691 (16.5%) of all Indigenous peoples died. Only 11.1% of non-Indigenous people died.

The proportion of deaths among Indigenous peoples was higher compared to non-Indigenous people inside the hospital (37.1% vs 36.3%, respectively) and in the ICU (52.9% and 51.6%). Deaths outside the hospital were also higher among Indigenous peoples (3.7% vs 1.7%).

Table 2. Hospital admission, ICU admission and deaths by ethnicity

| Risk Factors | Indigenous n = 4178 (1.0%) | Not Indigenous n = 412368 (99.0%) | Total n = 416546 |
|--------------|----------------------------|----------------------------------|-----------------|
| Diabetes     | 50477 (74.1%)              | 17660 (25.9%)                   | 113853          |
| COPD         | 4394 (66.2%)               | 2239 (33.8%)                    | 2267 (48.2%)    |
| High blood pressure | 64194 (75.9%) | 20383 (24.1%)                   | 2730 (48.9%)    |
| Chronic kidney disease | 5264 (62.3%) | 3180 (37.7%)                    | 2534 (48.5%)    |
| Obesity      | 68205 (85.6%)              | 14110 (14.4%)                   | 16930 (62.7%)   |
| Smoking      | 27001 (87.6%)              | 3817 (12.4%)                    | 3426 (38.6%)    |
| Diabetes     | 51359 (97.3%)              | 21552 (98.2%)                   | 32111 (97.3%)   |

Table 3 shows the distribution of sociodemographic characteristics and the prevalence of comorbidities and risk factors among Indigenous and non-Indigenous non-survivors. A higher proportion of Indigenous non-survivors died in almost all age groups compared to non-Indigenous people. Men are more likely to
die in both Indigenous and non-Indigenous people; however, Indigenous men and women were more likely to die from COVID-19 than non-Indigenous people. While a higher proportion of deaths happened in the public sector, Indigenous peoples were more likely to die in both sectors. Finally, a higher proportion of Indigenous peoples with comorbidities and risk factors died compared to non-Indigenous people.

Table 3. Sociodemographic characteristics and present comorbidities and risk factors among all non-survivors by ethnicity.

|                | Indigenous n = 691 | Non-Indigenous n = 45817 |
|----------------|-------------------|-------------------------|
| Age (years ± SD) | 63.4 ± 13.0       | 61.9 ± 13.8             |
| Age group       |                   |                         |
| 18-39           | 28 (2.3%)         | 2724 (1.7%)             |
| 40-49           | 73 (8.8%)         | 5828 (6.2%)             |
| 50-59           | 153 (18.0%)       | 10705 (14.0%)           |
| 60-69           | 94 (13.6%)        | 12599 (26.4%)           |
| 70 or older     | 243 (39.6%)       | 13961 (39.2%)           |
| Gender          |                   |                         |
| Female          | 230 (13.6%)       | 16128 (8.3%)            |
| Male            | 461 (18.5%)       | 29689 (13.6%)           |
| Sector          |                   |                         |
| Private         | 4 (12.1%)         | 561 (4.9%)              |
| Public          | 687 (16.6%)       | 45256 (11.3%)           |
| Comorbidities   |                   |                         |
| Diabetes        | 258 (28.7%)       | 17402 (25.9%)           |
| COPD            | 47 (34.8%)        | 2192 (33.7%)            |
| HBP             | 270 (29.6%)       | 20113 (24.0%)           |
| CKD             | 40 (44.4%)        | 3140 (37.6%)            |

Regarding our multiple logistic regression models (see table 4), we observed that, compared to non-Indigenous people, Indigenous peoples in general and those who received ambulatory care had significantly higher odds of dying (OR 1.13, 95%CI 1.03 to 1.24 in all COVID-19 patients; OR 1.55, 95%CI 1.24 to 1.92 in non-hospitalized patients). Interestingly, people treated in the public health care sector also had higher odds of death compared to people treated in the private sector in all the models. However, this was the only factor where the OR was higher among
hospitalized patients than non-hospitalized patients (OR 3.22, 95%CI 2.91 to 3.55 vs OR 2.14, 95%CI 1.72 to 2.71). Men, older people, patients with obesity and patients with comorbidities had higher odds of dying as well, especially among non-hospitalized patients.

Table 4. Multiple logistic regression models (ORs and 95%CIs) on all COVID-19 patients, hospitalized patients and non-hospitalized patients

|                          | All COVID-19 patients | Hospitalized patients | Non-hospitalized patients |
|--------------------------|-----------------------|-----------------------|---------------------------|

Discussion

To our knowledge, this is the most extensive study of hospital and ambulatory mortality of COVID-19 patients in Mexico. Among all patients, we found that patients who died were more likely to be older, men, Indigenous, receive treatment in the public sector, and have comorbidities and lifestyle risk factors. Similar to previous studies, we found that age, gender, and the presence of comorbidities are
important predictors of death among patients with COVID-19. (1, 2, 4, 5, 9–11)

Overall, Mexicans have a high burden of chronic diseases such as diabetes, high blood pressure, and chronic kidney disease, although the prevalence of some of these diseases seems to be higher among Indigenous peoples. (13–17) Our results show that a higher proportion of Indigenous peoples in almost all age groups, in both genders, and with comorbidities died in our sample, which suggests access to care and the quality of care might play a role on the impact of COVID-19 among Indigenous peoples.

We found that ethnicity was mostly associated with death in those who received ambulatory care even after adjusting for health care sector. This finding suggests that poor access to health care services might be a driver of higher mortality among Indigenous peoples. Despite progress in the socioeconomic and health conditions of Indigenous peoples in recent years, most of them remain uninsured or are affiliated to the public health care sector, which is often of poorer quality compared to the private sector. (12,18–20) Furthermore, one study found that Indigenous peoples in Mexico were less likely to receive any type of health care among those seeking medical care. (21) The current COVID-19 pandemic has strained health care systems worldwide. Therefore, an inequitable distribution of health resources could be playing a role in access to care as well. For example, municipalities with a high proportion of Indigenous peoples have only 63 clinics, 31 beds and 86 doctors per 100000, while those with a low proportion of Indigenous peoples have 377 clinics, 336 beds and 670 doctors per 100000. (12)
Our study had some limitations. Selection bias could be present as Mexico is mainly using a sentinel surveillance system to identify and report COVID-19 cases. This system mainly identifies people seeking care. Thus, asymptomatic and mild cases might be missed. This could be particularly problematic for our sample of patients who did not require hospitalization and, thus, our whole sample as well. Ethnicity was also missing in 12562 (2.9%) of 432501 adult patients with COVID-19. However, this percentage is much lower than previous studies conducted in the UK and Brazil. (4, 5) Ethnicity was determined in this data set by asking the patient if they spoke an Indigenous language. According to a recent national survey, 21.5% of Mexicans consider themselves Indigenous, but only 6.5% of the population actually spoke an Indigenous language. (22) Only 4178 (1.0%) patients spoke an Indigenous language in our sample, which suggests Indigenous peoples lack access to adequate testing and are, therefore, underrepresented in our sample. Finally, our models were not able to be adjusted for socioeconomic status. For this reason, we included health care sector as a variable in our model unlike previous studies in Mexico, as income is associated with insurance type.

Mexico is a racially and ethnically diverse country. However, most Mexicans are considered mestizos, or people of mixed European, African and Indian ancestry. This has resulted in the erasure of racial identities and it poses a challenge to the study of race in the country. (23) However, some studies have attempted to measure health inequities by using skin color rather than race self-identity. For example, one study showed that light brown, dark brown and black Mexicans had lower levels of self-rated health compared to White Mexicans. (24) We were only
able to classify ethnicity as Indigenous and non-Indigenous based on language.

Further research is need on how the COVID-19 pandemic has affected non-White Mexicans in general, regardless of self-identify.

Our study also has several strengths. To our knowledge, our study is the first study to address the impact of a pandemic in a specific vulnerable group, such as Indigenous peoples in Mexico. Our study adds to the growing evidence of how ethnic and racial inequities affect the health of REM across different settings in the world. Another key strength of the study was the large sample size with relatively few missing data for all the predictors that were analyzed. The large sample size also enabled high statistical power which yielded narrow confidence intervals for our multiple regression model. Our study also accounted for the health care sector in which patients were treated, which had not been included in previous studies conducted in Mexico.

In conclusion, we present evidence suggesting that Indigenous peoples in Mexico have a higher risk of death from COVID-19. Our results also suggest that access to care might be playing an important role on the impact of COVID-19 among Indigenous peoples. The COVID-19 pandemic has highlighted what we have known for quite a long time: Indigenous peoples and ethnic minorities continue to be marginalized, and urgent action is needed to address the health inequities that persist among the most vulnerable. Beyond addressing the current inequities in the COVID-19 response, the financial, social, and educational barriers need be addressed as well if we hope to achieve social and health justice for Mexican Indigenous peoples and other ethnic minorities.
Contributions: IIN planned the study with the input of KGFR, VRH, HCOB, ASZ, MPO, and RGSM. All authors designed the study, critically revised the manuscript for important intellectual content and approved the final version of the manuscript. IIN and KGFR acquired the data. IIN drafted the manuscript. IIN and KGFR did the statistical analysis. HCOB and RGSM serve as guarantors and affirm that the manuscript is an honest, accurate, and transparent account of the study being reported; that no important aspects of the study have been omitted; and any discrepancies from the study as originally planned (and, if relevant, registered) have been explained. All authors had full access to all of the data in the study and take responsibility for the integrity of the data and accuracy of the data analysis. The corresponding author attests that all listed authors meet authorship criteria, and that no others meeting the criteria have been omitted.

Copyright/license for publication: The Corresponding Author has the right to grant on behalf of all authors and does grant on behalf of all authors, a worldwide licence to the Publishers and its licensees in perpetuity, in all forms, formats and media (whether known now or created in the future), to i) publish, reproduce, distribute, display and store the Contribution, ii) translate the Contribution into other languages, create adaptations, reprints, include within collections and create summaries, extracts and/or, abstracts of the Contribution, iii) create any other derivative work(s) based on the Contribution, iv) to exploit all subsidiary rights in the Contribution, v) the inclusion of electronic links from the Contribution to third party material where-ever it may be located; and, vi) licence any third party to do any or all of the above.
**Ethical approval:** No ethics approval was required for this study.

**Role of the funding source:** There was no funding source for this study.

**Competing interests:** All authors have completed the ICMJE uniform disclosure form at www.icmje.org/coi_disclosure.pdf and declare: no support from any organization for the submitted work; no financial relationships with any organizations that might have an interest in the submitted work in the previous three years; and no other relationships or activities that could appear to have influenced the submitted work.

**Dissemination declaration:** The authors do not plan to disseminate the results of this study to patient groups.

**Data sharing:** The authors had full access to all the data in the study, which is available at [https://coronavirus.gob.mx/](https://coronavirus.gob.mx/). Requests for access to the data could also be addressed to IIN or KGFR. Requests for the statistical code should be made to IIN or KGFR.

Summary boxes

What is already known on this topic

• Racial and ethnic minorities have been reported to have an increased risk of COVID-19 transmission because they tend to live in densely populated areas and have essential jobs that do not allow them to easily implement preventive measures

• Racial and ethnic minorities have been reported to have increased risks of adverse outcomes from COVID-19 in other settings, but little is known about how COVID-19 is affecting Indigenous peoples in Mexico

What this study adds

• In a large national sample of patients with COVID-19, ethnicity was an independent risk factor for COVID-19 mortality, particularly in Indigenous peoples who were not hospitalized

• Even after controlling for comorbidities, more prevalent among Indigenous peoples, and sociodemographic factors, Indigenous peoples have had worse outcomes during the COVID-19 pandemic in Mexico

• COVID-19 mortality among Indigenous peoples is probably underestimated considering only 1% of our sample reported speaking an Indigenous language, compared to 6.5% of Mexicans who do
Figure 1. Flowchart of the data set by the MoH used for this study.

- 101,105,000 suspected cases of COVID-19 included in the data set

- 432,501 adult patients with a positive COVID-19 test

  - 125,622 had missing data on ethnicity

- 419,939 adult patients with their ethnicity recorded

  - 33,933 had missing data on health care sector where they received treatment

- 416,546 adult patients with health care sector recorded
