A HIGHER LIMIT APPROACH TO HOMOLOGY THEORIES

SERGEI O. IVANOV AND ROMAN MIKHAILOV

Abstract. A lot of well-known functors such as group homology, cyclic homology of algebras can be described as limits of certain simply defined functors over categories of presentations. In this paper, we develop technique for the description of the higher limits over categories of presentations and show that certain homological functors can be described in this way. In particular, we give a description of Hochschild homology and the derived functors of tensor, symmetric and exterior powers in the sense of Dold and Puppe as higher limits.

1. Introduction

Let \( k \) be a ring, \( \text{Mod}(k) \) the category of \( k \)-modules and let \( \mathcal{C} \) be a category such that for any two objects \( c \) and \( c' \) there exists a morphism \( f : c \to c' \). Then for a functor \( F : \mathcal{C} \to \text{Mod}(k) \) the limit \( \varprojlim \mathcal{F} \) is the largest constant subfunctor in \( \mathcal{F} \). Therefore, one can perceive \( \varprojlim \mathcal{F} \) as the largest part of \( \mathcal{F}(c) \) which does not dependent on \( c \).

Let \( A \) be an “algebraic object” (group, abelian group, associative algebra, ...). We denote by \( \text{Pres}(A) \) the category of presentations of \( A \) as a quotient of a free object \( F \to A \). This category satisfies the condition above and a lot of interesting “homology theories of \( A \)” can be described as limits of simple functors \( \text{Pres}(A) \to \text{Mod}(k) \) without use of homological algebra. D. Quillen in [12] proved that if \( A \) is an algebra over a field of characteristic zero, then even cyclic homology can be described as the limit

\[
HC_{2n}(A) = \varprojlim F/(I_{n+1} + [F, F]).
\]

The limit is taken over the category of presentations \( I \to F \to A \), where \( F \) is a free algebra. In other words, \( HC_{2n}(A) \) is the largest part of \( F/(I^n + [F, F]) \) independent of the presentation \( I \to F \to A \). He also proved the similar formula for the odd reduced cyclic homology:

\[
\overline{HC}_{2n+1}(A) = \varprojlim I_{n+1}/[I, I^n].
\]

I. Emmanouil and R. Mikhailov [4] proved the similar formulas for the case of group homology:

\[
H_{2n}(G, M) = \varprojlim R_{ab}^{\otimes n} \otimes_{\mathbb{Z}[G]} M.
\]

The limit is taken over the category of presentations \( R \to F \to G \), where \( F \) is a free group and \( R_{ab} \) is the relation module. Further R. Mikhailov and I. B. S. Passi [10] described the highest nonzero Dold-Puppe derived functors of symmetric, exterior and tensor powers as limits in the category of free presentations of an abelian group. In this article we prove the following formula for even Hochschild homology of an algebra \( A \) over a field of any characteristic:

\[
H_{2n}(A, M) = \varprojlim (I^n/I_{n+1}) \otimes_{A^e} M,
\]

This research is supported by the Chebyshev Laboratory (Department of Mathematics and Mechanics, St. Petersburg State University) under RF Government grant 11.G34.31.0026 and by JSC "Gazprom Neft". The first author is supported by RFBR (grant no. 12-01-31100 mol_a, 13-01-00902 A).
where $A^e = A \otimes A^{\text{op}}$.

The most exiting thing in this approach is the fact that a lot of homology theories can be described without any recourse to homological algebra but using only presentations. Moreover, thanks to the interpretation of a limit as the largest part independent of presentation this description is very intuitive. On the other hand, this approach shows that homologies can be useful in work with an algebraic object by means of its presentation. The additional advantage of this approach is that it gives a way to observe different maps between homology theories. If we denote

$$H_{2n}(A) = \lim_{\leftarrow} (F/I^{n+1})$$

for algebras over a field of characteristic zero to the following formulas (see theorem 7.11)

$$H_{2n-i}(G, M) = \lim_{\leftarrow} R^n_{ab} \otimes_{\mathbb{Z}[G]} M, \quad \text{for } i < n,$$

$$H_{2n-i}(A, M) = \lim_{\leftarrow} (I^n/I^{n+1}) \otimes_{A^e} M, \quad \text{for } i < n,$$

and give the following description of the derived functors of symmetric, exterior and tensor powers (see theorem 8.1)

$$L_{n-i}^S(A) = \lim_{\leftarrow} \Lambda^n(H),$$

$$L_{n-i}^\Lambda(A) = \lim_{\leftarrow} \Gamma^n(H),$$

$$L_{n-i} \otimes^n (A) = \lim_{\leftarrow} \otimes^n(H).$$

The limits are taken over the category of presentations $H \rightarrow F \rightarrow A$, where $F$ is a free abelian group. The formulas (1.1)–(1.2) are generalised for the case of augmented algebras over a field of characteristic zero to the following formulas (see theorem 7.11)

$$H_{2n-i}(A) = \lim_{\leftarrow} F/(I^{n+1} + [F, F]), \quad \text{for } i \in \{0, 1\},$$

$$H_{2n-i}(A) = \lim_{\leftarrow} I^{n+1}/[I, I^n], \quad \text{for } i \in \{0, 1\}.$$

These formulas describe the homology theories for all indexes. It should be noted that any commutative algebra $A$ of finite type over the field $\mathbb{C}$ has an augmentation $A \rightarrow \mathbb{C}$. Thus the formulas (1.11) and (1.12) hold for all coordinate algebras of affine complex varieties.

Further, we give another point of view on group homology through the higher limits. Let $R \hookrightarrow F \twoheadrightarrow G$ be a presentation of a group $G$. Denote by $F_n(\pi)$ the $n$th fibred power
Then there are recurrence relations, which express higher homologies through the first homologies (see theorem 5.3)

\[(1.13) \quad H_{2n-2}(G, M) = \lim_{\leftarrow} H_{n-1}(F_n(\pi), M) \quad \text{for } n \geq 2,\]

\[(1.14) \quad H_{2n-3}(G, M) = \lim^1 H_{n-1}(F_n(\pi), M) \quad \text{for } n \geq 3.\]

Furthermore, we compute limits of some higher relation modules. For example, if \(G\) is a 2-torsion-free group then

\[(1.15) \quad \lim_{\leftarrow} [R, R]/[R, R, F] = H_4(G, \mathbb{Z}/2),\]

\[(1.16) \quad \lim^1 [R, R]/[R, R, F] = H_3(G, \mathbb{Z}/2).\]

The paper is organized as follows. In section 2 we recall the theory of representations of categories \([16], [6], [14]\). In section 3 we develop technique of computing of higher limits of representations of categories with pairwise coproducts. The main result in this section is proposition 3.1 which allows to compute the higher limits for so-called monoadditive functors. Section 4 is devoted to 4-term exact sequences of the form \(\mathcal{H}_*(A) \rightarrow \mathcal{F}_1 \rightarrow \mathcal{F}_2 \rightarrow \mathcal{H}_{*-1}(A)\) where \(\mathcal{F}_i\) are representations of \(\text{Pres}(A)\) and \(\mathcal{H}_*(A)\) is a one of the homology theories of an algebraic object \(A\) (considered as a constant functor). These sequences are very useful for computing of higher limits. Sections 5, 7, 8 are devoted to higher limit formulas of homology theories for groups, algebras and abelian groups respectively, and in section 6 we compute higher limits for some higher relation modules over groups.

2. Representations of categories and higher limits.

In this section we recall several facts about representations of categories and higher limits and colimits which the reader can find in \([16], [6], [14]\) with more details and proofs (see also \([11]\)).

2.1. Representations of categories. Let \(k\) be a commutative ring and \(\mathcal{C}\) be a category. Using considerations of Grothendieck universes we assume that all categories are small for an appropriate universe. By definition, a representation of \(\mathcal{C}\) (over \(k\)) is a functor \(\mathcal{F} : \mathcal{C} \rightarrow \text{Mod}(k)\). The category of representations \(\text{Mod}(k)^\mathcal{C}\) is an abelian category with enough projectives and injectives, and a sequence in this category is exact if and only if it is exact objectwise. Denote by \(k\mathcal{C}\) the category algebra of \(\mathcal{C}\) i.e. the algebra with the basis \(\text{Mor}(\mathcal{C})\) whose multiplication is induced by the composition and vanishes for non-composable morphisms. This algebra has an identity element if and only if \(\mathcal{C}\) has finitely many objects. The category of representations is naturally embedded into the category of (left) \(k\mathcal{C}\)-modules as an abelian subcategory:

\[\text{Mod}(k)^\mathcal{C} \hookrightarrow \text{Mod}(k\mathcal{C}), \quad \mathcal{F} \mapsto \bigoplus_{c \in \mathcal{C}} \mathcal{F}(c),\]

and its image consists of \(k\mathcal{C}\)-modules \(M\) such that \(M = \bigoplus_{c \in \mathcal{C}} \text{id}_c \cdot M\). We will identify a representation of \(\mathcal{C}\) and the corresponding \(k\mathcal{C}\)-module. All these definitions extend the corresponding notions for groups considered as a category with one object and for quivers which are replaced by the associated free categories.
2.2. Higher limits and cohomology. Consider the diagonal functor $\text{Mod}(k) \to \text{Mod}(k)^C$ which sends a $k$-module $M$ to a constant functor $C \to \text{Mod}(k)$ sending all objects to $M$ and all morphisms to $\text{id}_M$. We denote this constant representation by the same symbol $M : C \to \text{Mod}(k)$. Then the limit and colimit functors $\lim, \lim : \text{Mod}(k)^C \to \text{Mod}(k)$ are defined as the right and the left adjoint functors to the diagonal functor. Therefore, we have the natural isomorphisms:

$$\text{Hom}_{kC}(M, F) \cong \text{Hom}_k(M, \lim F), \quad \text{Hom}_{kC}(F, M) \cong \text{Hom}_k(\lim F, M),$$

for any representation $F$ and any $k$-module $M$. Since $\lim$ is a right adjoint functor, it is a left exact additive functor. Hence it has right derived functors, and similarly $\lim$ has left derived functors.

$$\lim^i = R^i \lim, \quad \lim_i = L_i \lim.$$  

The $n$th homology and cohomology group of $C$ with coefficients in a representation $F$ are defined as follows:

$$H_n(C, F) = \text{Tor}^k_n(k, F), \quad H^n(C, F) = \text{Ext}^n_k(k, F).$$

For any $n \geq 0$ there are isomorphisms

$$\lim^n F \cong H^n(C, F), \quad \lim F \cong H_n(C, F).$$

2.3. Preserving of higher limits. Recall that the nerve of a category $C$ is a simplicial set $\mathbb{N}C : \Delta^{op} \to \text{Sets}$ given by the formula $\mathbb{N}C = \text{Cat}(-, C)$ (here we consider $\Delta$ as a full subcategory of $\text{Cat}$ where $[n]$ is a free category generated by the graph $0 \to 1 \to \cdots \to n$), and the classifying space of the category $C$ is the geometrical realization of its nerve $BC = |\mathbb{N}C|$. A functor $\Phi : C \to D$ induces a morphism of simplicial sets $\Phi \circ \mathbb{N} : \mathbb{N}C \to \mathbb{N}D$ and a continuous map $B\Phi : BC \to BD$. Moreover, a natural transformation $\alpha : \Phi_1 \to \Phi_2$ induces a homotopy $B\alpha$ between $B\Phi_1$ and $B\Phi_2$ [11, §1 proposition 2]. (One could say that $B$ is a strict 2-functor.)

For a $k$-module $M$ the (co)homology groups of $C$ with coefficients in the constant representation $M$ are isomorphic to (co)homology groups of the classifying space $BC$ with coefficients in $M$:

$$H_n(C, M) = H_n(BC, M), \quad H^n(C, M) = H^n(BC, M).$$

A category $C$ is said to be contractible if its classifying space $BC$ is contractible and it is said to be $k$-acyclic if the reduced homology groups $\tilde{H}_*(BC, k)$ vanish. Of course, a contractible category is $k$-acyclic.

Let $\Phi : C \to D$ be a functor. For an object $d \in D$ we denote by $\Phi \downarrow d$ the comma category (see [9]) consisting of objects $(c, \alpha)$, where $c \in C$ and $\alpha \in D(\Phi(c), d)$. A morphism in the comma category from $(c, \alpha)$ to $(c', \alpha')$ is given by $f : c \to c'$, which satisfies $\alpha \Phi(f) = \alpha'$. If $C = D$ and $\Phi = \text{id}_D$, the corresponding comma category is denoted by $D \downarrow d$.

**Proposition 2.1.** (see [9, 5.4]). Let $\Phi : C \to D$ be a functor satisfying the condition that $\Phi \downarrow d$ is $k$-acyclic for any $d \in D$. Then for any representation $F$ of $D$ there is an isomorphism

$$\theta_\Phi : \lim^n F \cong \lim^n(F\Phi),$$

which is natural by $F$ and $\Phi$. 
Remark 2.2. In the previous proposition by the naturalness by $\Phi$ we mean that for a natural transformation $\alpha : \Phi_1 \to \Phi_2$ of functors satisfying the condition of the proposition we have $\alpha_n : \lim^n(\mathcal{F}\Phi_1) \to \lim^n(\mathcal{F}\Phi_2)$ is the map induced by $\alpha$. In [9] the fact that the isomorphism is natural did not state, but it follows easily from the proof and the fact that the obvious map $\theta^0_\Phi : \lim \mathcal{F} \to \lim(\mathcal{F}\Phi)$ is natural by $\mathcal{F}$ and $\Phi$.

Corollary 2.3. Let $\Phi_1, \Phi_2 : \mathcal{C} \to \mathcal{D}$ be functors satisfying the condition of proposition 2.1 and $\alpha : \Phi_1 \to \Phi_2$ is a natural transformation. The induced homomorphism $\alpha_n : \lim^n(\mathcal{F}\Phi_1) \to \lim^n(\mathcal{F}\Phi_2)$ is an isomorphism.

Proof. Since the isomorphism in proposition 2.1 is natural by $\Phi$, there is a commutative diagram

$$
\begin{array}{ccc}
\lim^n \mathcal{F} & \cong & \lim^n(\mathcal{F}\Phi_1) \\
\alpha^n & \cong & \alpha_n \\
\lim^n(\mathcal{F}\Phi_2) & \cong & \lim^n \mathcal{F}
\end{array}
$$

Hence, $\alpha_n$ is an isomorphism.

Lemma 2.4. Left adjoint functors satisfy the condition of proposition 2.1. In particular, if $\Phi : \mathcal{C} \to \mathcal{D}$ is a left adjoint functor and $\mathcal{F}$ is a representation of $\mathcal{D}$, then there is an isomorphism $\lim^n \mathcal{F} \cong \lim^n(\mathcal{F}\Phi)$ for any $n \geq 0$.

Proof. Let $\Psi : \mathcal{D} \to \mathcal{C}$ be a right adjoint functor to $\Phi$. Then the comma category $\Phi \downarrow \mathcal{D}$ has a terminal object which is given by the the pair $(\Psi(d), \varepsilon_d)$, where $\varepsilon_d : \Phi \Psi(d) \to d$ is the counit of adjunction ([9], IV.1). Thus the category $\Phi \downarrow \mathcal{D}$ is contractible ([11], §1 Corollary 2]).

2.4. Spectral sequence of higher limits.

Proposition 2.5. Let $\Phi : \mathcal{A} \to \mathcal{B}$ be a left exact functor between abelian categories with enough injectives and $a^\bullet \in \text{Com}_+(\mathcal{A})$ be a bounded below complex with $\Phi$-acyclic cohomologies. Then there exists a cohomological spectral sequence $E$ of objects of $\mathcal{B}$ so that

$$E \Rightarrow \Phi(H^n(a^\bullet)) \quad \text{and} \quad E_1^{pq} = R^q\Phi(a^p).$$

Proof. Consider an injective Cartan-Eilenberg resolution $I^\bullet$ of $a^\bullet$ with an injection $a^\bullet \hookrightarrow I^{\bullet,0}$ and differentials $d^i_{pq} : I^p \to I^{p+1,q}$ and $d^i_{pq} : I^p \to I^{p,q+1}$. Then there are two spectral sequences $E$ and $E$ associated with the bicomplex $B^{\bullet \bullet} = \Phi(I^{\bullet \bullet})$ which converge to the cohomology of the totalisation $H^n(\text{Tot}(B^{\bullet \bullet}))$ so that $E_1^{pq} = H^n_{\text{II}}(B^{\bullet \bullet})$, $E_2^{pq} = H^n_\Phi(\text{Tot}(B^{\bullet \bullet}))$ and $\Pi E_1^{pq} = H^n_\Pi(B^{\bullet \bullet})$, $\Pi E_2^{pq} = H^n_{\text{II}}(H^n_\Phi(B^{\bullet \bullet}))$. Since $I^{\bullet \bullet}$ is a Cartan-Eilenberg resolution, the complex $I^{\bullet \bullet}$ is homotopy equivalent to the complex of its cohomologies $H^n_\Phi(I^{\bullet \bullet})$ with zero differentials, and hence $H^n_{\text{II}}(H^n_\Phi(B^{\bullet \bullet})) = \text{R}^q\Phi(H^n_\Phi(a^\bullet))$. The complex $H^n_{\text{II}}(I^{\bullet \bullet})$ is an injective resolution of $H^n_\Phi(a^\bullet)$. It follows that $H^n_{\text{II}}(H^n_\Phi(B^{\bullet \bullet})) = \text{R}^q\Phi(H^n_\Phi(a^\bullet))$. Using the fact that the objects $H^n(a^\bullet)$ are $\Phi$-acyclic, we obtain

$$E_2^{pq} = \begin{cases} 0, & q \neq 0 \\ \Phi(H^n(a^\bullet)), & q = 0. \end{cases}$$

Hence we get $H^n(\text{Tot}(B^{\bullet \bullet})) = \Phi(H^n(a^\bullet))$. Therefore the spectral sequence $E := E$ converges to $\Phi(H^n(a^\bullet))$, and since $I^{p,\bullet}$ is an injective resolution of $a^p$, we have $E_1^{pq} = H^n_\Phi(I^{p,\bullet}) = \text{R}^q\Phi(a^p)$.

$\square$
Corollary 2.6. Let $\mathcal{F}^\bullet$ be a bounded below complex of representations of a category $\mathcal{C}$ with $\varprojlim$-acyclic cohomologies. Then there exists a cohomological spectral sequence $E$ such that

\[ E \Rightarrow \varprojlim H^n(\mathcal{F}^\bullet) \quad \text{and} \quad E_1^{pq} = \varprojlim^q \mathcal{F}^p. \]

3. Representations of categories with pairwise coproducts.

3.1. Shifting of higher limits. Let $\mathcal{C}$ be a category with pairwise coproducts i.e. for any objects $c_1, c_2 \in \mathcal{C}$ there exists the coproduct $c_1 \xrightarrow{i_1} c_1 \sqcup c_2 \xleftarrow{i_2} c_2$ in $\mathcal{C}$ ($\mathcal{C}$ is not necessary has an initial object). For any representation $\mathcal{F}$ of $\mathcal{C}$ there is a natural transformation

\[ (3.1) \quad \tau_{\mathcal{F},c} : \mathcal{F}(c) \oplus \mathcal{F}(c) \rightarrow \mathcal{F}(c \sqcup c), \]

given by $\tau_{\mathcal{F},c} = (\mathcal{F}(i_1), \mathcal{F}(i_2))$. A representation $\mathcal{F}$ of $\mathcal{C}$ is said to be additive (resp. monoadditive, epiaadditive) if $\tau_{\mathcal{F}}$ is an isomorphism (resp. monomorphism, epimorphism). If we put $\mathcal{F}_{sq}(c) = \mathcal{F}(c \sqcup c)$, we can write the previous natural transformation as $\tau_{\mathcal{F}} : \mathcal{F}^2 \rightarrow \mathcal{F}_{sq}$.

By a representation $\mathcal{F}$ we construct the representation $\Sigma^n \mathcal{F} := \text{coker}(\tau_{\mathcal{F}})$, and by recursion $\Sigma^{n+1} \mathcal{F} = \Sigma(\Sigma^n \mathcal{F})$. Then a representation $\mathcal{F}$ is monoadditive if and only if the following sequence is exact

\[ (3.2) \quad 0 \rightarrow \mathcal{F}^2 \xrightarrow{\tau_{\mathcal{F}} \mathcal{F}} \mathcal{F}_{sq} \rightarrow \Sigma \mathcal{F} \rightarrow 0 \]

Proposition 3.1. Let $\mathcal{C}$ be a category with pairwise coproducts and $\mathcal{F}$ be a monoadditive representation of $\mathcal{C}$. Then there is an isomorphism

\[ (3.3) \quad \varprojlim^n \mathcal{F} \cong \varprojlim^{n-1} \Sigma \mathcal{F} \]

for any $n \geq 0$.

Corollary 3.2. If $\mathcal{F}$ is a monoadditive representation of a category with pairwise coproducts, then $\varprojlim \mathcal{F} = 0$.

Corollary 3.3. If $\mathcal{F}$ is a representation of a category with pairwise coproducts such that the functor $\Sigma^n \mathcal{F}$ is monoadditive for $0 \leq n < l$, then

\[ (3.4) \quad \varprojlim^n \mathcal{F} = \varprojlim^{n-l} \Sigma^l \mathcal{F} \]

for any $n \geq 0$. In particular, $\varprojlim^n \mathcal{F} = 0$ for $0 \leq n < l$.

Corollary 3.4. If $\mathcal{F}$ is an additive representation of a category with pairwise coproducts, then $\varprojlim^n \mathcal{F} = 0$ for any $n \geq 0$.

In order to prove proposition 3.1 we need to prove two lemmas. The following lemma seems to be well-known, but we provide a proof for completeness.

Lemma 3.5. A category $\mathcal{C}$ with pairwise coproducts is contractible.

Proof. Chose an object $c_0 \in \mathcal{C}$ and consider the functor $\Phi : \mathcal{C} \rightarrow \mathcal{C}$ given by the formula $\Phi(\mathcal{F}) = - \sqcup c_0$. By definition of coproduct, we obtain natural transformations from the identity functor $\text{Id}_\mathcal{C} \rightarrow \Phi$ and from the constant functor $\text{Const}_{c_0} \rightarrow \Phi$. Using the fact that a natural transformation of two functors induces a homotopy between the corresponding continuous maps on the classifying spaces, we obtain that the identity map of the classifying space $\text{id}_{\mathcal{C}}$ is homotopic to $B\Phi : B\mathcal{C} \rightarrow B\mathcal{C}$, and the map $B\Phi$ is homotopic to the constant map $\text{const}_{c_0}$. Therefore, $\text{id}_{\mathcal{C}} \sim \text{const}_{c_0}$, and hence, $\mathcal{C}$ is contractible. \[\square\]
Lemma 3.6. Let $F$ be a representation of a category with coproducts. Then the morphisms $i_1, i_2 : c \to c \sqcup c$ induce isomorphisms

$$(3.5) \quad (i_k)_* : \lim^n F(c) \xrightarrow{\cong} \lim^n F(c \sqcup c).$$

Proof. We denote by $sq$ a functor $C \to C$ given by $c \mapsto c \sqcup c$. Then $F_{sq} = F \circ sq$. An object of the comma category $sq \downarrow c_0$ is a pair $(c, \alpha : c \sqcup c \to c_0)$. An arrow $\alpha : c \sqcup c \to c_0$ is defined by the pair of arrows $\alpha_1 = \alpha \circ i_1 : c \to c_0$ and $\alpha_2 = \alpha \circ i_2 : c \to c_0$. Thus the category $sq \downarrow c_0$ is isomorphic to the category, whose objects are triples $(c, \alpha_1 : c \to c_0, \alpha_2 : c \to c_0)$ and morphisms $f : (c, \alpha_1, \alpha_2) \to (c', \alpha_1', \alpha_2')$ are morphisms $f : c \to c'$ such that $\alpha_1' f = \alpha_1$ and $\alpha_2' f = \alpha_2$. It is easy to see that the object $(c \sqcup c', \alpha_1 + \alpha_1', \alpha_2 + \alpha_2')$ is the coproduct of objects $(c, \alpha_1, \alpha_2)$ and $(c', \alpha_1', \alpha_2')$ in this category. Hence the category $sq \downarrow c_0$ has coproducts and by lemma 3.5 it is contractible. Therefore, the functor $sq$ satisfies the condition of proposition 2.3. Finally, applying corollary 2.3 to the natural transformation $i_k : \text{Id}_C \to sq$, we obtain the claimed isomorphism. 

Proof of proposition 2.3 Consider the long exact sequence of higher limits associated with the short exact sequence $0 \to F \oplus F \to F_{sq} \to F' \to 0$. Using lemma 3.6 we obtain that the homomorphism $((i_1)_*, (i_2)_*) : \lim^n F \oplus \lim^n F \to \lim^n F_{sq}$ is an epimorphism, and hence the map $\lim^n F_{sq} \to \lim^n F'$ vanishes. Therefore we get the short exact sequences

$$(3.6) \quad 0 \to \lim^n F' \to \lim^{n+1} F \oplus \lim^{n+1} F \to \lim^{n+1} F_{sq} \to 0,$$

which are the totalisations of the bicartesian squares

$$\begin{array}{ccc}
\lim^n F' & \xrightarrow{s_1} & \lim^{n+1} F \\
\downarrow s_2 & & \downarrow \cong (i_1)_* \\
\lim^{n+1} F & \xrightarrow{(i_2)_*} & \lim^{n+1} F_{sq}.
\end{array}$$

By lemma 3.6 $(i_1)_*$ and $(i_2)_*$ are isomorphisms, and hence $s_1$ and $s_2$ are isomorphisms. 

3.2. Relative additivity and vanishing of higher limits. We denote by $\text{Mod}$ the category of modules over $k$-algebras. Its objects are pairs $(A, M)$ where $A$ is an algebra, $M$ is an $A$-module and a morphism $(A, M) \to (B, N)$ is a pair $(\varphi, f)$ where $\varphi : A \to B$ is a morphism of algebras and $f : M \to N$ is a linear map such that $f(am) = \varphi(a)f(m)$. If $M$ is an $A$-module, $N$ is a $B$-module and $\varphi : A \to B$ is a homomorphism of algebras, we will denote by $N_{\varphi}$ the reduced $A$-module, and by $M_{\varphi} = B \otimes_A M$ the induced $B$-module. If $f$ is obvious we denote $N_{\varphi} = N_{\varphi} = M^B := M^\varphi$. Then for a morphism $f : (A, M) \to (B, N)$, the map $f$ can be considered as an $A$-homomorphism $f : M \to N_{\varphi}$. Since the functor $\uparrow \varphi$ is left adjoint to $\varphi$, a homomorphism $f : M \to N_{\varphi}$ induces a homomorphism $f^\# : M^\varphi \to N$ given by $f^\# (b \otimes m) = b \cdot f(m)$. 
Let $\mathcal{C}$ be a category with coproducts and $\mathcal{O}: \mathcal{C} \to \text{Alg}$ be a functor to the category of $k$-algebras. $\mathcal{O}$-representation is a functor $\mathcal{F}: \mathcal{C} \to \text{Mod}$ such that the diagram

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{\mathcal{F}} & \text{Mod} \\
\downarrow \mathcal{O} & & \downarrow \\
\text{Alg} & & \\
\end{array}
\]

is commutative, where the right-hand functor is given by $(A, M) \mapsto A$. Hence $\mathcal{F}(c)$ could be written as $(\mathcal{O}(c), \mathcal{F}_m(c))$, where $\mathcal{F}_m(c)$ is a $\mathcal{O}(c)$-module. We will usually consider $\mathcal{F}(c)$ not as a pair but as the vector space $\mathcal{F}_m(c)$ with the fixed structure of $\mathcal{O}(c)$-module.

For an algebra $A$ we denote by $A^{\text{op}}$ the opposite algebra with multiplication $a \ast b = ba$. Similarly for a functor $\mathcal{O}: \mathcal{C} \to \text{Alg}$ we denote by $\mathcal{O}_{\text{op}}$ the functor given by $\mathcal{O}_{\text{op}}(c) = \mathcal{O}(c)^{\text{op}}$. If $\mathcal{F}$ is an $\mathcal{O}$-representation and $\mathcal{H}$ is an $\mathcal{O}_{\text{op}}$-representation, then one can define the representation $\mathcal{H} \otimes_{\mathcal{O}} \mathcal{F}: \mathcal{C} \to \text{Mod}(k)$ given by $(\mathcal{H} \otimes_{\mathcal{O}} \mathcal{F})(c) = \mathcal{H}(c) \otimes_{\mathcal{O}(c)} \mathcal{F}(c)$.

Let $\mathcal{C}$ be a category with pairwise coproducts. An $\mathcal{O}$-representation $\mathcal{F}$ is said to be additive if the morphism

\[(3.7) \quad T_\mathcal{F}: \mathcal{F}(c) \uparrow_{i_1} \oplus \mathcal{F}(c) \uparrow_{i_2} \rightarrow \mathcal{F}(c \sqcup c)
\]

is an isomorphism of $\mathcal{O}(c \sqcup c)$-modules, where $T_\mathcal{F} = (\mathcal{F}(i_1)^\#, \mathcal{F}(i_2)^\#)$.

**Proposition 3.7.** Let $\mathcal{C}$ be a category with pairwise coproducts, $\mathcal{O}: \mathcal{C} \to \text{Alg}$ be a functor, $\mathcal{F}$ be an additive $\mathcal{O}$-representation and $\mathcal{H}$ be an $\mathcal{O}_{\text{op}}$-representation. Then

\[\lim^i \mathcal{H} \otimes_{\mathcal{O}} \mathcal{F} = 0 \quad \text{for any } i \geq 0.\]

**Proof.** We put $t_{l,c} := \mathcal{H}(i_l) : \mathcal{H}(c) \to \mathcal{H}(c \sqcup c) \downarrow_{i_l}$ and $\sigma_l \mathcal{H} := \text{coker}(t_l)$ for $l \in \{1, 2\}$. Since $(\text{id}_c, \text{id}_c) \circ i_l = \text{id}_c$, the morphism $t_{l,c}$ is a $\mathcal{O}(c)$-split monomorphism, and hence $\mathcal{H}(c \sqcup c) \downarrow_{i_l} \cong \mathcal{H}(c) \oplus \sigma_l \mathcal{H}(c)$. Consider a commutative diagram

\[
\begin{array}{ccc}
\bigoplus_{l \in \{1, 2\}} \mathcal{H}(c \sqcup c) \downarrow_{i_l} \otimes_{\mathcal{O}(c)} \mathcal{F}(c) & \xrightarrow{id \otimes T_\mathcal{F}} & \mathcal{H}(c \sqcup c) \otimes_{\mathcal{O}(c \sqcup c)} \mathcal{F}(c \sqcup c) \\
(t_1 \otimes \text{id}_{\mathcal{F}(c)}) \oplus (t_2 \otimes \text{id}_{\mathcal{F}(c)}) & & \\
\bigoplus_{l \in \{1, 2\}} \mathcal{H}(c) \otimes_{\mathcal{O}(c)} \mathcal{F}(c) & & \mathcal{T}_{\mathcal{H} \otimes_{\mathcal{O}} \mathcal{F}, c}
\end{array}
\]

Since $t_l$ is a $\mathcal{O}(c)$-split monomorphism, the left-hand morphism is a split monomorphism, and hence $\mathcal{H} \otimes_{\mathcal{O}} \mathcal{F}$ is monoadditive. Moreover, we obtain $\Sigma(\mathcal{H} \otimes_{\mathcal{O}} \mathcal{F}) = \bigoplus_{l \in \{1, 2\}} \sigma_l \mathcal{H} \otimes_{\mathcal{O}} \mathcal{F} = (\sigma_1 \mathcal{H} \oplus \sigma_2 \mathcal{H}) \otimes_{\mathcal{O}} \mathcal{F}$. Using the fact that $\Sigma(\mathcal{H} \otimes_{\mathcal{O}} \mathcal{F})$ has the same form as $\mathcal{H} \otimes_{\mathcal{O}} \mathcal{F}$ and induction, we get that $\Sigma^n(\mathcal{H} \otimes_{\mathcal{O}} \mathcal{F})$ is monoadditive for all $n$, and thus, $\lim^i (\mathcal{H} \otimes_{\mathcal{O}} \mathcal{F}) = 0$. 

\[\square\]

4. 4-TERM EXACT SEQUENCES

A natural way to get different presentations of homology groups as derived limits is to use certain homological 4-term exact sequences of the form

Homology(object) $\hookrightarrow$ Functor$_1$(presentation) $\rightarrow$ Functor$_2$(presentation) $\rightarrow$ Homology(object) $\rightarrow$
Generally such sequences appear from homological spectral sequences. Here we give the examples of 4-term sequences and related computations of $\lim\lim^1$-functors in two cases: 1) group homology, 2) cyclic homology of algebras.

4.1. Relation modules and group homology. For a group $G$, consider a free presentation of $G$:

$$1 \to R \to F \xrightarrow{\pi} G \to 1,$$

where $F$ is a free group with a generating set $S$. The augmentation ideal $\Delta(F) = \ker\{Z[F] \to Z\}$ of $F$ is the free $Z[F]$-module on the set $\{s-1 : s \in S\}$. There is an exact sequence of $ZG$-modules

$$0 \to R_{ab} \xrightarrow{\mu} ZG \otimes_{Z[F]} \Delta(F) \xrightarrow{\sigma} \Delta(G) \to 0,$$

where $\mu$ maps $r[R, R]$ onto $1 \otimes (r-1)$ for all $r \in R$, $\sigma$ maps the basis element $1 \otimes (s-1)$ onto $\pi(s)-1$ for all $s \in S$ and $\Delta(G)$ is the augmentation ideal in the group ring $Z[G]$. The map $\mu$ is called the Magnus embedding of the relation module $R_{ab}$.

Let $M$ be a $Z[G]$-module. The module $M$ can be viewed as a module over $R$ and $F$ where the action of $R$ is trivial and the action of $F$ is induced by the action of $G$. Consider the homology spectral sequence for the extension (4.1) with the coefficients $M$:

$$E^2_{pq} = H_p(G, H_q(R, M)) \Rightarrow H_{p+q}(F, M).$$

Since all homology groups of $R$ and $F$ are zero in dimensions $\ge 2$, this spectral sequence gives the natural isomorphisms:

$$E^2_{p,0} = H_p(G, M) \overset{d^2_{p,0}}{\to} E^2_{p-2,1} = H_{p-2}(G, R_{ab} \otimes M), \ p \ge 3,$$

and the following 4-term exact sequence:

$$0 \to H_2(G, M) \to H_0(G, R_{ab} \otimes M) \to H_1(F, M) \to H_1(G, M) \to 0.$$  

For $n \ge 1$, take the module $R_{ab}^{\otimes n} \otimes M$ as coefficients in homology. The sequence (4.4) and isomorphism (4.3) induce the following 4-term exact sequence:

$$0 \to H_{2n}(G, M) \to H_0(G, R_{ab}^{\otimes n} \otimes M) \to H_1(F, R_{ab}^{\otimes n-1} \otimes M) \to H_{2n-1}(G, M) \to 0.$$  

Observe that, for $n \ge 2$,

$$\lim_{\leftarrow} H_1(F, R_{ab}^{\otimes n-1} \otimes M) = \lim_{\leftarrow}^1 H_1(F, R_{ab}^{\otimes n-1} \otimes M) = 0.$$  

For the proof see the proof of theorem 5.3. The exact sequence (4.5) and triviality of limits (4.6) implies that, for $n \ge 2$,

$$\lim_{\leftarrow} H_0(G, R_{ab}^{\otimes n} \otimes M) = H_{2n}(G, M)$$

$$\lim_{\leftarrow}^1 H_0(G, R_{ab}^{\otimes n} \otimes M) = H_{2n-1}(G, M).$$  

In the next section we will show how to extend this result to the higher limits.

Now we will consider the similar 4-term sequence, where the homology group is presented not as a kernel, but as a cokernel.

**Proposition 4.1.** The sequence (4.2) induces the following 4-term exact sequence

$$0 \to H_1(F, R_{ab} \otimes M) \to H_1(F, Z[G] \otimes_{Z[F]} \Delta(F) \otimes M) \to H_1(F, \Delta(G) \otimes M) \to H_2(G, M) \to 0$$
Proof. Applying the functor $H_*(F, -)$ to the Magnus embedding, we get three left terms of the needed sequence. It remains to show that the image of the boundary map

$$H_1(F, \Delta(G) \otimes M) \to H_0(F, R_{ab} \otimes M)$$

is exactly $H_2(G, M)$. This follows from the natural commutative diagram

$$\begin{array}{ccc}
H_1(F, \Delta(G) \otimes M) & \longrightarrow & H_0(F, R_{ab} \otimes M) \\
\downarrow & & \downarrow \\
H_1(G, \Delta(G) \otimes M) & \longrightarrow & H_0(G, R_{ab} \otimes M)
\end{array}$$

and the isomorphism $H_1(G, \Delta(G) \otimes M) = H_2(G, M)$. \qed

**Corollary 4.2.** For $n \geq 1$, there is the following exact 4-term sequence

$$(4.7) \quad 0 \to H_1(F, R_{ab}^\otimes \otimes M) \to H_1(F, R_{ab}^\otimes \otimes \mathbb{Z}[G] \otimes \mathbb{Z}[F] \Delta(F) \otimes M) \to H_1(F, R_{ab}^\otimes \otimes \Delta(G) \otimes M) \to H_{2n}(G, M) \to 0$$

### 4.2. Quillen sequences.

Let $k$ be a field of characteristic zero, $E$ an associative $k$-algebra, $I$ a two-sided ideal of $E$ and $M$ an $E$-bimodule. Let $\mathcal{B}(E)$ be the free bimodule resolution of $E$: $\mathcal{B}(E)_n = E^\otimes_{n+2}$, $(n + 2)$-fold tensor product over $k$, $n \geq 0$, with differential $b'$ given by

$$b'(x_0 \otimes \ldots \otimes x_{n+1}) = \sum_{j=0}^{n} (-1)^j (x_0 \otimes \ldots \otimes x_j x_{j+1} \otimes \ldots \otimes x_{n+1}), x_i \in E.$$

Following [12], denote by $M \otimes_E$ the Hochschild homology group $H_0(E, M)$; set

$$M \otimes_E^n = M \otimes_E \mathcal{B}(E) \otimes_E \ldots \otimes_E \mathcal{B}(E) \otimes_E \ldots$$

and denote by $(M \otimes_E^n)_{/n}$ its quotient under the the action the cyclic group $\mathbb{Z}/n$.

Recall from [12] (Theorem 5.5) that there exists the following spectral sequence

$$E^1_{pq} = H_{q-p}((E \otimes_E^n)_{/n+1}/(I \otimes_E^n)_{/n+1}) \Rightarrow HC_{p+q}(E/I).$$

In the case $E$ is free, the spectral sequence collapses to the exact sequence (for $n \geq 1$)

$$HC_{2n}(E/I) \longrightarrow E^1_{nn} \xrightarrow{d^n_{nn}} E^1_{n-1,n} \longrightarrow HC_{2n-1}(E/I)$$

Since, for $n \geq 1$, $HC_0(E/I_{n+1}) = E/(I_{n+1} + [E, E])$, where $[E, E]$ is the $k$-submodule of $R$ generated by $rs - sr$, $r, s \in E$, one has the following 4-term sequence:

$$(4.8) \quad 0 \to HC_{2n}(E/I) \to E/(I_{n+1} + [E, E]) \to H_1(E, E/I_{n}) \to HC_{2n-1}(E/I) \to 0$$
The similar spectral sequence argument is used in [12] (Theorem 5.11) for an analogous 4-term spectral sequence for the odd dimensional reduced cyclic homology (for \( n \geq 0 \)):

\[
0 \to \overline{HC}_{2n+1}(E/I) \to I^{n+1}/[I, I^n] \to H_1(E, I^n) \to \overline{HC}_{2n}(E/I) \to 0
\]

Note that, by definition, \( H_1((E/I^n)\otimes_E) = H_1(E, E/I^n) \).

5. Group homology as higher limits

5.1. Group homology. In this section, we will consider the category \( \text{Pres}(G) \) of free presentations of a group \( G \). The objects of \( \text{Pres}(G) \) are surjective homomorphisms \( \pi : F \twoheadrightarrow G \) where \( F \) is a free group and morphisms \( f : (\pi_1 : F_1 \twoheadrightarrow G) \rightarrow (\pi_2 : F_2 \twoheadrightarrow G) \) are homomorphisms \( f : F_1 \rightarrow F_2 \) such that \( \pi_1 = \pi_2 f \). The category \( \text{Pres}(G) \) has coproducts given by

\[
(\pi_1 : F_1 \twoheadrightarrow G) \sqcup (\pi_2 : F_2 \twoheadrightarrow G) = (\pi_1 + \pi_2 : F_1 * F_2 \twoheadrightarrow G),
\]

and hence it is contractible. In particular, for any abelian group \( A \) higher limits \( \lim^i A \) vanish for \( i > 0 \). We will always denote by \( R \) the kernel of an epimorphism \( \pi : F \twoheadrightarrow G \). Therefore an object of \( \text{Pres}(G) \) defines a short exact sequence of groups

\[
1 \rightarrow R \rightarrow F \xrightarrow{\pi} G \rightarrow 1,
\]

and \( R \) can be considered as a functor \( R : \text{Pres}(G) \rightarrow \text{Gr} \). All the limits considered below in this section are taken over the category \( \text{Pres}(G) \).

**Theorem 5.1.** For a group \( G \) and a \( \mathbb{Z}[G] \)-module \( M \), for \( n \geq 1 \), there are natural isomorphisms

\[
\lim^i H_0(G, R_{ab}^\otimes \otimes M) = \begin{cases} H_{2n-i}(G, M) & \text{for } i < n, \\ 0 & \text{for } i > n \end{cases}
\]

For \( i = n \), there is a natural short exact sequence

\[
0 \rightarrow H_n(G, M) \rightarrow \lim_{\leftarrow} H_0(G, R_{ab}^\otimes \otimes M) \rightarrow (\Delta(G)^{\otimes n-1} \otimes M)\Delta(G) \rightarrow 0
\]

**Corollary 5.2.** For any group \( G \) and \( n \geq 1 \), there are natural isomorphisms

\[
H_{2n-i}(G) = \lim^i (R_{ab}^\otimes)_G \text{ for } i < n.
\]

**Proof.** First lets prove the theorem for \( n = 1 \). Observe that the representation \( H_1(F, M) \) is monoadditive and

\[
\Sigma H_1(F, M) = M\Delta(G).
\]

Hence, by proposition 3.1

\[
\lim^i H_1(F, M) = \begin{cases} M\Delta(G) & \text{for } i = 1 \\ 0 & \text{for } i \neq 1 \end{cases}
\]

The needed isomorphisms follow now from the sequence (1.4) and corollary 2.6 applied to the complex

\[
H_0(G, R_{ab} \otimes M) \rightarrow H_1(F, M)
\]

whose zeroth homology is \( H_1(G, M) \) and the first homology is \( H_2(G, M) \). For \( i = n = 1 \), the spectral sequence 2.6 implies that there is following natural short exact sequence

\[
0 \rightarrow H_1(G, M) \rightarrow \lim^1 H_0(G, R_{ab} \otimes M) \rightarrow M\Delta(G) \rightarrow 0.
\]
In particular, for a trivial \( \mathbb{Z}[G] \)-module \( M \), there is an isomorphism

\[
H_1(G, M) = \lim_{\leftarrow}^1 H_0(G, R_{ab} \otimes M).
\]

Now assume that the isomorphisms (5.1) are proved for a given \( n \). Consider the next step. Since the category \( \text{Pres}(G) \) is acyclic, the 4-term sequence (4.5) implies that there is a natural isomorphism

\[
\lim_{\leftarrow}^i H_0(G, R_{ab}^{n+1} \otimes M) = \lim_{\leftarrow}^i H_1(F, R_{ab}^n \otimes M), \quad i \geq 2.
\]

For any \( \mathbb{Z}[G] \)-module \( N \) (which may depend on \( F \) and \( R \)),

\[
\lim_{\leftarrow}^i H_1(F, \mathbb{Z}[G] \otimes \mathbb{Z}[F] \Delta(F) \otimes N) = 0, \quad i \geq 0
\]

Now the sequence (4.7) implies that

\[
\lim_{\leftarrow}^i H_1(F, R_{ab}^n \otimes M) = \lim_{\leftarrow}^{i-1} W_n(F, R), \quad n \geq 1
\]

for all \( i \geq 0 \), where \( W_n(F, R) \) is the part of the following short exact sequence

\[
0 \to W_n(F, R) \to H_1(F, R_{ab}^{n-1} \otimes \Delta(G) \otimes M) \to H_{2n}(G, M) \to 0.
\]

First consider the case \( i = 2 \). For \( n \geq 2 \),

\[
\lim_{\leftarrow}^i H_1(F, R_{ab}^{n-1} \otimes \Delta(G) \otimes M) = 0, \quad i = 0, 1.
\]

Therefore, there is a natural isomorphism

\[
H_{2n}(G, M) = \lim_{\leftarrow}^1 W_n(F, R) = \lim_{\leftarrow}^2 H_1(F, R_{ab}^n \otimes M) = \lim_{\leftarrow}^2 H_0(F, R_{ab}^{n+1} \otimes M)
\]

and (5.1) follows for \( i = 2 \). In the case \( n = i = 2 \), we get the natural exact sequence

\[
0 \to H_2(G, M) \to \lim_{\leftarrow}^2 H_0(F, R_{ab}^2 \otimes M) \to \Delta(G) \otimes M) \Delta(G) \to 0,
\]

where the last term comes from the isomorphism

\[
\lim_{\leftarrow}^1 H_1(F, \Delta(G) \otimes M) = (\Delta(G) \otimes M) \Delta(G).
\]

For \( i \geq 3 \), there is a natural isomorphism

\[
\lim_{\leftarrow}^i H_1(F, R_{ab}^n \otimes M) \cong \lim_{\leftarrow}^{i-1} H_1(F, R_{ab}^{n-1} \otimes \Delta(G) \otimes M).
\]

Since

\[
\lim_{\leftarrow}^{i-1} H_1(F, R_{ab}^{n-1} \otimes \Delta(G) \otimes M) = \lim_{\leftarrow}^{i-1} H_0(G, R_{ab}^n \otimes \Delta(G) \otimes M),
\]

the inductive assumption implies that

\[
\lim_{\leftarrow}^i H_1(F, R_{ab}^n \otimes M) = \begin{cases} H_{2n-i+1}(G, \Delta(G) \otimes M) = H_{2n-i+2}(G, M) & \text{for } i < n + 1 \\ 0 & \text{for } i > n + 1 \end{cases}
\]

For \( i = n + 1 \), we get the natural exact sequence

\[
0 \to H_{n+1}(G, M) \to \lim_{\leftarrow}^{n+1} H_0(G, R_{ab}^{n+1} \otimes M) \to (\Delta(G)^{\otimes n} \otimes M) \Delta(G) \to 0
\]

and the inductive step is completed for \( i \geq 3 \). \( \square \)
5.2. **Fibre products.** For \( n \geq 2 \) and an epimorphism \( p : F \to G \), consider the fibre product

\[
F_n(\pi) := F \times_G \cdots \times_G F = \{(x_1, \ldots, x_n) \in F^{\times n} \mid \pi(x_1) = \cdots = \pi(x_n)\}
\]

There is a natural split exact sequence \((n \geq 2)\):

\[
(5.2) \quad 1 \to R \to F_n(\pi) \to F_{n-1}(\pi) \to 1.
\]

For any \( \mathbb{Z}[G] \)-module \( M \), there is a split exact sequence of homology groups which follows from the spectral sequence applied to the extension \((5.2)\):

\[
(5.3) \quad 0 \to H_i(F_{n-1}(\pi), R_{ab} \otimes M) \to H_{i+1}(F_n(\pi), M) \to H_{i+1}(F_{n-1}(\pi), M) \to 0.
\]

For \( i = n - 1 \), we have a natural isomorphism

\[
(5.4) \quad H_n(F_n(\pi), M) \simeq H_1(F, R_{ab}^{\otimes n-1} \otimes M).
\]

**Theorem 5.3.** For any \( \mathbb{Z}[G] \)-module \( M \), there are natural isomorphisms

\[
(5.5) \quad \varprojlim H_{n-1}(F_n(\pi), M) = H_{2n-2}(G, M) \text{ for } n \geq 2
\]

\[
(5.6) \quad \varprojlim^1 H_{n-1}(F_n(\pi), M) = H_{2n-3}(G, M) \text{ for } n \geq 3.
\]

**Proof.** We first show that

\[
(5.7) \quad \varprojlim H_1(F_2(\pi), M) = H_2(G, M).
\]

To see this, consider the short exact sequence

\[
0 \to H_0(F, R_{ab} \otimes M) \to H_1(F_2(\pi), M) \to H_1(F, M) \to 0
\]

The representation \( H_1(F, M) \) is monoadditive, hence \( \varprojlim H_1(F, M) = 0 \). Now the isomorphism \((5.7)\) follows from theorem \((5.1)\) for \( n = 1, i = 0 \).

Now we can assume that \( n \geq 3 \). We will show that, for any module \( N \) (which may depend on \( F \) and \( R \)) and \( k \geq 1 \),

\[
(5.8) \quad \varprojlim H_1(F, R_{ab}^{\otimes k} \otimes N) = \varprojlim^1 H_1(F, R_{ab}^{\otimes k} \otimes N) = 0.
\]

For a presentation \( F/R = G \), consider its free square:

\[
1 \to \tilde{R} \to F \ast F \to G \to 1,
\]

where \( \tilde{R} \) is the kernel of the natural projection \( F \ast F \to G \), which sends both copies of \( F \) via \( p \). The representation \( H_1(F, R_{ab}^{\otimes k} \otimes N) \) is monoadditive. The cokernel \( Cok(F, R) \) of the natural map

\[
H_1(F, R_{ab}^{\otimes k} \otimes N) \otimes 2 \to H_1(F \ast F, \tilde{R}_{ab}^{\otimes n} \otimes N)
\]
can be described with the help of Mayer-Vietoris sequence for group homology of a free product as follows. There is a natural diagram

\[
\begin{array}{cccccc}
H_1(F, R_{ab}^\otimes \otimes N)^{\otimes 2} & \rightarrow & H_1(F, R_{ab}^\otimes \otimes N)^{\otimes 2} \\
\downarrow & & \downarrow \\
H_1(F * F, R_{ab}^\otimes \otimes N) & \rightarrow & H_1(F * F, \tilde{R}_{ab}^\otimes \otimes N) & \rightarrow & H_1(F * F, \tilde{R}_{ab}^\otimes \otimes N) \\
\downarrow & & \downarrow & & \downarrow \\
\Delta(G)(R_{ab}^\otimes \otimes N) & \rightarrow & \text{Cok}(F, R) & \rightarrow & \text{Coker}(\text{inj}) \\
\end{array}
\]

The triviality of \( \lim^1 \) in (5.8) now follows from proposition 3.1, since both representations \( R_{ab}^\otimes \otimes N \) and \( H_1(F * F, \tilde{R}_{ab}^\otimes \otimes N) \) are monoadditive.

The exact sequence (5.3) for \( i \leq n - 2 \), and the isomorphism (5.4) imply that

\[
\lim^i H_{n-1}(F_n(\pi), M) = \lim^i H_{n-2}(F_{n-1}(\pi), R_{ab} \otimes M), \quad \text{for } j = 0, 1.
\]

Continuing this process, we get the isomorphisms

\[
\lim^i H_{n-1}(F_n(\pi), M) = \lim^i H_0(F, R_{ab}^{n-1} \otimes M), \quad \text{for } j = 0, 1.
\]

The needed statement now follows from theorem 5.1.

6. Higher relation modules

For a free presentation of a group \( G \),

\[
1 \rightarrow R \rightarrow F \rightarrow G \rightarrow 1,
\]

the lower central series quotients \( \gamma_n(R)/\gamma_{n+1}(R) \) are called higher relation modules. Here \( \{\gamma_n(R)\}_{n \geq 1} \) is the lower central series of \( R \) defined inductively as \( \gamma_1(R) = R, \ \gamma_{n+1}(R) = [\gamma_n(R), R] \). The action of \( G \) on \( \gamma_n(R)/\gamma_{n+1}(R) \) is defined via conjugation in \( F \). The properties of functors

\[
\lim^i \gamma_n(R)/[\gamma_n(R), F] = \lim^i H_0(G, \gamma_n(R)/\gamma_{n+1}(R))
\]

are considered in [4]. These functors are interesting since the map between higher relation modules and tensor powers of the ordinal relation module

\[
\begin{array}{cccc}
(\text{the } n\text{th Lie power of } R_{ab} =) & \gamma_n(R)/\gamma_{n+1}(R) & \rightarrow & R_{ab}^\otimes \rightarrow \gamma_n(R)/\gamma_{n+1}(R) \\
\end{array}
\]

induces, for all \( 0 \leq i < n \), the natural map between corresponding limits

\[
\lim^i \gamma_n(R)/[\gamma_{n+1}(R), F] \rightarrow H_{2n-i}(G) \rightarrow \lim^i \gamma_n(R)/[\gamma_{n+1}(R), F]
\]

by corollary 5.2. Here we describe the functor (6.2) for \( n = 2 \).
Proposition 6.1. There is a natural isomorphism

\[
\lim_{\text{lim}} \gamma_2(R)[/\gamma_2(R), F] = H_2(G, S^2(\Delta(G))),
\]

where \( S^2 \) is the symmetric square functor. If \( G \) is a 2-torsion-free group, then

\[
\lim_{\text{lim}} \gamma_2(R)[/\gamma_2(R), F] = H_4(G, \mathbb{Z}/2) \]

(6.5)

\[
\lim_{\text{lim}}^1 \gamma_2(R)[/\gamma_2(R), F] = H_3(G, \mathbb{Z}/2).
\]

Proof. Recall that, for a short exact sequence of free abelian groups

\[
0 \to A \to B \to C \to 0,
\]

there exists a natural long exact sequence, called the Koszul complex

\[
0 \to \Lambda^2(A) \to A \otimes B \to S^2(B) \to S^2(C) \to 0,
\]

where \( \Lambda^2 \) is the exterior square functor. Using the Magnus embedding instead of (6.6), we obtain the following exact sequence, which is a sequence not only of abelian groups, but also of \( \mathbb{Z}[G] \)-modules:

\[
0 \to \Lambda^2(R_{ab}) \to R_{ab} \otimes (\mathbb{Z}[G] \otimes \mathbb{Z}[F] \Delta(F)) \to S^2(\mathbb{Z}[G] \otimes \mathbb{Z}[F] \Delta(F)) \to S^2(\Delta(G)) \to 0
\]

Denote

\[
N(R, F) := R_{ab} \otimes (\mathbb{Z}[G] \otimes \mathbb{Z}[F] \Delta(F))
\]

and the cokernel of the left hand map in the above sequence

\[
Cok(F, R) := \text{coker}\{\Lambda^2(R_{ab}) \hookrightarrow N(F, R)\}
\]

After applying the functor \( H_*(G, -) \) to the exact sequence of \( \mathbb{Z}[G] \)-modules

\[
0 \to \Lambda^2(R_{ab}) \to N(F, R) \to Cok(F, R) \to 0
\]

we obtain the sequence

\[
0 \to H_1(G, Cok(F, R)) \to \gamma_2(R)[/\gamma_2(R), F] \to H_0(G, N(F, R)) \to H_0(G, Cok(F, R)) \to 0.
\]

Now we observe that \( H_0(F, N(F, R)) \) is a monoadditive representation and the sequence (6.8) implies that there is an isomorphism

\[
\lim_{\text{lim}} H_1(G, Cok(F, R)) = \lim_{\text{lim}} \gamma_2(R)[/\gamma_2(R), F].
\]

Recall that, for any group \( G \) and a free \( \mathbb{Z}[G] \)-module \( P \), \( H_{2k}(G, S^2(P)) = 0 \), \( k \geq 1 \) and \( H_i(G, S^2(P)) = 0 \) for all \( i \) if \( G \) is 2-torsion-free. The description of \( Cok(F, R) \) as a kernel

\[
0 \to Cok(F, R) \to S^2(\mathbb{Z}[G] \otimes \mathbb{Z}[F] \Delta(F)) \to S^2(\Delta(G)) \to 0
\]

implies that there is the following exact sequence

\[
0 \to H_2(G, S^2(G)) \to H_1(G, Cok(F, R)) \to H_1(G, S^2(\mathbb{Z}[G] \otimes \mathbb{Z}[F] \Delta(F)) \to 0
\]

Again we observe that \( H_1(G, S^2(\mathbb{Z}[G] \otimes \mathbb{Z}[F] \Delta(F)) \) is a monoadditive representation. The sequence (6.11) implies that

\[
\lim_{\text{lim}} H_1(G, Cok(F, R)) = \lim_{\text{lim}} H_2(G, S^2(G)) = H_2(G, S^2(G))
\]

and (6.3) follows from (6.9).
Now assume that \( G \) is 2-torsion-free. Then \( H_1(G, \text{Cok}(F, R)) = H_2(G, S^2(G)) = H_4(G, \mathbb{Z}/2) \) (see, for example, \([8]\)) and the isomorphism \((6.4)\) follows. To compute \( \lim^{-1}_1 \)-term, consider the sequence \((6.8)\) and observe that \( \lim^{-1}_i H_1(G, \text{Cok}(F, R)) = 0, \ i \geq 1 \), hence

\[
\lim^{-1}_1 \gamma_2(R)/[\gamma_2(R), F] = \lim H_0(G, \text{Cok}(F, R)).
\]

Applying the homology functor \( H_* \) to the sequence \((6.10)\) we get the exact sequence

\[
0 \to H_1(G, S^2(\Delta(G))) \to H_0(G, \text{Cok}(F, R)) \to H_0(G, S^2(\Delta(G))) \to H_0(G, S^2(\Delta(G))) \to 0.
\]

The representation \( H_0(G, S^2(\mathbb{Z}[G] \otimes_{\mathbb{Z}[F]} \Delta(F))) \) is monoadditive, hence

\[
\lim H_0(G, \text{Cok}(F, R)) = \lim H_1(G, S^2(\Delta(G))) = H_1(G, S^2(\Delta(G))) = H_3(G, \mathbb{Z}/2)
\]

and the isomorphism \((6.5)\) follows. \(\square\)

One can use the results and methods from \([8]\) and \([13]\) to get the descriptions of limits like \((6.4)\) and \((6.5)\). For example, consider the next higher relation module. In order to compute the limit

\[
\lim \gamma_3(R)/[\gamma_3(R), F]
\]

consider the following exact sequence from \([13]\):

\[
0 \to H_1(G, K_1^3) \to \gamma_3(R)/[\gamma_3(R), F] \to H_0(G, \mathbb{Z}[G] \otimes_{\mathbb{Z}[F]} \Delta(F) \otimes S^2(R_{ab})) \to H_0(G, K_1^3) \to 0,
\]

where \(K_1^3\) is a \(\mathbb{Z}[G]\)-module which lives in the following diagram with short exact sequences

\[
R_{ab} \otimes S^2(\Delta(G)) \quad \longrightarrow \quad S^3(\mathbb{Z}[G] \otimes_{\mathbb{Z}[F]} \Delta(F)) \quad \longrightarrow \quad S^3(\mathbb{Z}[G] \otimes_{\mathbb{Z}[F]} \Delta(F))
\]

\[
\quad \downarrow \quad K_1^3 \quad \downarrow \quad S^3(\mathbb{Z}[G] \otimes_{\mathbb{Z}[F]} \Delta(F))
\]

\[
\quad \downarrow \quad S^3(\Delta(G))
\]

Suppose that \( G \) is a 3-torsion-free group. Then the torsion subgroup of the quotient \( \gamma_3(R)/[\gamma_3(R), F] \) consists of 3-torsion elements only \([13]\). The reasoning from the proof of proposition \((6.1)\) leads to the following:

for a 3-torsion-free group \( G \), \( \lim \gamma_3(R)/[\gamma_3(R), F] = H_4(G, \mathbb{Z}/3) \).

### 7. Hochschild and Cyclic homology.

Let \( k \) be a field. All algebras in this section are assumed to be associative unital algebras over \( k \), and \( \otimes = \otimes_k \). If \( F \) is an algebra and \( M \) is an \( F \)-bimodule, we denote by \( F^e = F \otimes F^{op} \) the enveloping algebra of \( F \) and following Quillen we denote the space of coinvariants \( M_3 := M/[F, M] = H_0(F, M) \).
7.1. **Magnus embedding for algebras.** Let $A_1$ and $A_2$ be algebras and $L$ and $N$ be $(A_1, A_2)$-bimodules. A **bimodule derivation** $\delta : L \to N$ is a $k$-linear map such that $\delta(amb) = \delta(am)b - a\delta(m)b + a\delta(mb)$. Given a left-right split short exact sequence of $(A_1, A_2)$-bimodules

$$0 \to N \xrightarrow{f} M \xrightarrow{g} L \to 0 \quad (7.1)$$

one associates to it a bimodule derivation by choosing to it for $f$ a left $A_1$-splitting $l : L \to M$ and a right $A_2$-splitting $r : L \to M$. There is then a unique $k$-linear map $\delta : L \to N$ such that $g\delta = l - r$ and this map is a bimodule derivation.

Let $B_1 = A_1/I_1$ and $B_2 = A_2/I_2$ be quotient algebras and $M$ be a $(A_1, A_2)$-bimodule. Then we put $M^{(B_1, B_2)} := M/(I_1M + MI_2) \cong B_1 \otimes_{A_1} M \otimes_{A_2} B_2$. It gives a well defined functor $(-)^{(B_1, B_2)} : \text{Bimod}(A_1, A_2) \to \text{Bimod}(B_1, B_2)$. For the sake of simplicity, we put $\uparrow := \uparrow^{(B_1, B_2)}$.

**Lemma 7.1.** ([2, proposition 3.2]) As above, let $(7.1)$ be a right-left split sequence of $(A_1, A_2)$-bimodules, let $\delta : L \to N$ be an associated bimodule derivation and $B_i = A_i/I_i$ be quotient algebras. Then there is an exact sequence of $(B_1, B_2)$-bimodules

$$\frac{I_1M \cap MI_2}{I_1MI_2} \to \frac{I_1L \cap LI_2}{I_1LI_2} \xrightarrow{\delta} N^{\uparrow} \xrightarrow{f^{\uparrow}} M^{\uparrow} \xrightarrow{g^{\uparrow}} L^{\uparrow} \to 0,$$

where $\bar{\delta}$ is the bimodule homomorphism induced by $\delta$.

We denote by $\Omega(A)$ the universal derivation $A$-bimodule of a $k$-algebra $A$. It is defined as the kernel of the multiplication map $\Omega(A) = \ker(\mu : A \otimes A \to A)$. The universal derivation $\delta : A \to \Omega(A)$ is given by $\delta(a) = a \otimes 1 - 1 \otimes a$, and it is the associated bimodule derivation to the left-right split short exact sequence

$$0 \to \Omega(A) \to A \otimes A \xrightarrow{\mu} A \to 0 \quad (7.2)$$

with splittings $l(a) = a \otimes 1$ and $r(a) = 1 \otimes a$. Let $\bar{A}$ denote the vector space quotient $A/k$. Then there is a well-defined isomorphism of vector spaces $A \otimes \bar{A} \cong \Omega(A)$ given by $x \otimes \bar{y} \mapsto x \otimes y - xy \otimes 1$ (see [3, proposition 10.1.3]). The composition of $\delta$ with this isomorphism is the map $A \to A \otimes \bar{A}$ given by $a \mapsto 1 \otimes \bar{a}$. It follows that

$$\ker(\delta) = k \quad \text{and} \quad \coker(\delta) = \bar{A}^{\otimes 2}. \quad (7.3)$$

Let $B = A/I$ be a quotient algebra, then we denote the enveloping algebra by $B^e = B \otimes B^{op}$ and $\uparrow^{B^e} \equiv \uparrow^{(B, B)} : \text{Bimod}(A) \to \text{Bimod}(B)$.

**Proposition 7.2.** Let $A$ be a $k$-algebra and $B = A/I$ be its quotient algebra. Then there is an exact sequence of $B$-bimodules

$$0 \to I/I^2 \xrightarrow{\bar{\delta}} \Omega(A)^{(B, B)} \xrightarrow{d} B \otimes B \xrightarrow{\mu} B \to 0,$$

where $\mu$ is the multiplication map, $d$ is induced by inclusion $\Omega(A) \hookrightarrow A \otimes A$ and $\bar{\delta}$ is induced by the universal derivation $\delta : A \to \Omega(A)$.

**Proof.** It follows from the previous lemma and the equations $B = A^{(B, B)}$, $B \otimes B = (A \otimes A)^{(B, B)}$, $I/I^2 = (IA \cap AI)/(IAI)$ and $((I \otimes A) \cap (A \otimes I))/(I \otimes I) = 0$. $\square$
If $F$ is a (quasi-)free algebra and $A \cong F/I$, then $A$-bimodule $I/I^2$ is said to be a relation bimodule. By the previous proposition we have a short exact sequence of $A$-bimodules

$$(7.4) \quad 0 \to I/I^2 \xrightarrow{\delta} \Omega(F)^{\uparrow Ae} \to \Omega(A) \to 0.$$  

$\Omega(F)$ is a projective $F$-bimodule, and hence, $\Omega(F)^{\uparrow Ae}$ is a projective $A$-bimodule. Since $\Omega(A)$ is left-right projective, the sequence (7.4) left-right splits, and hence $I/I^2$ is left-right projective. The map $\delta : I/I^2 \to \Omega(F)^{\uparrow Ae}$ is called Magnus embedding of the relation bimodule $I/I^2$.

### 7.2. Higher limit formula for Hochschild homology.

In this section, we will consider the category $\text{Pres}(A)$ of free presentations of an algebra $A$. The objects of $\text{Pres}(A)$ are surjective homomorphisms $\pi : F \to A$ where $F$ is a free algebra and morphisms $f : (\pi_1 : F_1 \to A) \to (\pi_2 : F_2 \to A)$ are homomorphisms $f : F_1 \to F_2$ such that $\pi_1 = \pi_2 f$. The category $\text{Pres}(G)$ has coproducts given by $(\pi_1 : F_1 \to G) \sqcup (\pi_2 : F_2 \to G) = (\pi_1 + \pi_2 : F_1 * F_2 \to G)$, where $F_1 * F_2$ is the free product of algebras. Therefore this category is contracible. In particular, for any vector space $V$ higher limits $\lim^i V$ vanish for $i > 0$. We will always denote by $I$ the kernel of an epimorphism $\pi : F \to A$. Hence an object of $\text{Pres}(G)$ defines a short exact sequence

$$(7.5) \quad 1 \to I \to F \xrightarrow{\pi} A \to 1.$$  

and $I$ can be considered as a functor $I : \text{Pres}(A) \to \text{Mod}(A)$. All the limits considered below in this section are taken over the category $\text{Pres}(A)$.

**Lemma 7.3.** If we consider $F^e$ as a functor $F^e : \text{Pres}(A) \to \text{Alg}$, sending $(F \to A)$ to $F^e$, then for any $F^e$-representation $\mathcal{H}$ of the category $\text{Pres}(A)$

$$\lim^i \mathcal{H} \otimes_{F^e} \Omega(F) = 0$$

for all $i$.

**Proof.** It follows from proposition [3.7] and the fact that $\Omega(F)$ is a $F^e$-additive representation (see [1] 2.3). \hfill \Box

**Lemma 7.4.** Let $F$ be a quasi-free algebra, $I$ its ideal and $A = F/I$. Then the map induced by multiplication

$$(I^n/I^{n+1}) \otimes_A (I^m/I^{m+1}) \to I^{n+m}/I^{n+m+1}$$

is an isomorphism of $A$-bimodules. In particular, $(I/I^2)^{\otimes_n}_A \cong I^n/I^{n+1}$.

**Proof.** It is sufficient to prove that the multiplication map induces an isomorphism $(I/I^2)^{\otimes_n}_A \cong I^n/I^{n+1}$ for any two ideals $I, J \triangleleft F$ (of any algebra $F$) there is a short exact sequence

$$(7.6) \quad 0 \to \text{Tor}^F_1(F/I, F/J) \to I \otimes_F J \to IJ \to 0$$

where the right-hand map is the multiplication map. Since $F$ is quasi-free, its global dimension is less than or equal to 1, and hence $I \otimes_F J \cong IJ$ for any ideals $I, J$ of $F$. By induction we obtain $I^{\otimes_n} \cong I^n$. Applying the functor $- \otimes_F A$ to the last isomorphism, we get $I^{\otimes_{n-1}} \otimes_F (I/I^2) \cong I^n/I^{n+1}$. Finally, using the isomorphism $I \otimes_F (I/I^2) \cong (I/I^2) \otimes_A (I/I^2)$, we obtain $(I/I^2)^{\otimes_n}_A \cong I^n/I^{n+1}$. \hfill \Box
Lemma 7.5. For any $A$-bimodule $M$ the following holds
\[ \lim_{\leftarrow}^i (I^n/I^{n+1}) \otimes_A M = \begin{cases} \Omega_{\text{nc}}^n(A) \otimes_A M, & \text{if } i = n \\ 0, & \text{if } i \neq n \end{cases} \]
for $n \geq 0$, where $\Omega_{\text{nc}}^n(A) = \Omega(A)^{\otimes n}$ (see [5]).

Proof. Consider the left-right split exact sequence of Magnus embedding
\[ \frac{I}{I^2} \to \Omega(F)^{\uparrow A^e} \to \Omega(A). \]
Tensoring by $(I^n/I^{n+1}) \otimes_A M$, we obtain the following short exact sequence
\[ 0 \to (I^n/I^{n+1}) \otimes_A M \to \Omega(F)^{\uparrow A^e} \otimes_A (I^n/I^{n+1}) \otimes_A M \to \Omega(A) \otimes_A (I^n/I^{n+1}) \otimes_A M \to 0. \]
If we denote $L := (I^n/I^{n+1}) \otimes_A M$, the middle term can be written as follows
\[ (A \otimes_F \Omega(F) \otimes_F A) \otimes_A L = A \otimes_F \Omega(F) \otimes_F L = (L \otimes A) \otimes_{F^e} \Omega(F). \]
By lemma 7.3 all the higher limits of the middle term vanish. Then using the long exact sequence and the fact that $\Omega(A)$ is a projective as a left $A$-module, we obtain
\[ \lim_{\leftarrow}^i ((I^n/I^{n+1}) \otimes_A M) = \lim_{\leftarrow}^i (\Omega(A) \otimes (I^n/I^{n+1}) \otimes_A M) = \Omega(A) \otimes \lim_{\leftarrow}^i ((I^n/I^{n+1}) \otimes_A M). \]
Then by induction we get the claimed statement. \hfill \qed

Theorem 7.6. For an algebra $A$ and an $A$-bimodule $M$, for $n \geq 1$, there are natural isomorphism
\[ H_{2n-i}(A, M) \simeq \lim_{\leftarrow}^i (I^n/I^{n+1}) \otimes_{A^e} M \text{ for } i < n. \]

Corollary 7.7. There is an isomorphism
\[ HH_{2n-i}(A) \simeq \lim_{\leftarrow}^i (I^n/I^{n+1}) \text{ for } i < n. \]

Proof. If $P$ is a projective $A$-bimodule and $M$ and $N$ are left-right projective $A$-bimodules then $P \otimes_A M$ is a projective $A$-bimodule and $M \otimes_A N$ is left-right projective. It follows from the fact that the functors $\text{Hom}_{A^e}(P \otimes A, M, -) \cong \text{Hom}_{A^e}(P, \text{Hom}_{A}(M, -))$, $\text{Hom}_{A}(M \otimes A N, -) \cong \text{Hom}_{A}(M, \text{Hom}_{A}(N, -))$ and $\text{Hom}_{A^e}(P \otimes A, N, -) \cong \text{Hom}_{A^e}(P, \text{Hom}_{A^e}(N, -))$ are exact.

The Magnus embedding gives the following exact sequence of representations $I/I^2 \to \Omega(F)^{\uparrow A^e} \to A^e \to A$. Then tensoring by $I^n/I^{n+1}$ we obtain exact sequences
\[ 0 \to I^{n+1}/I^{n+2} \to \Omega(F)^{\uparrow A^e} \otimes_A (I^n/I^{n+1}) \to A^e \otimes_A (I^n/I^{n+1}) \to I^n/I^{n+1} \to 0. \]
Consider the projective resolution $P_\bullet$ of the bimodule $A$ given by the infinite Yoneda product of these sequences. Then $P_{2n} = A^e \otimes_A (I^n/I^{n+1})$ and $P_{2n+1} = \Omega(F)^{\uparrow A^e} \otimes_A (I^n/I^{n+1})$ and there is an embedding $I^n/I^{n+1} \to P_{2n-1}$. Since $P_\bullet$ is a projective resolution, the homology of the complex $P_\bullet \otimes_{A^e} M$ coincides with $H_i(A, M)$. Let $F^\bullet$ be the following cochain complex concentrated in non-negative degrees:
\[ 0 \to (I^n/I^{n+1}) \otimes_{A^e} M \to P_{2n-1} \otimes_{A^e} M \to P_{2n-2} \otimes_{A^e} M \to \ldots \to P_0 \otimes_{A^e} M \to 0. \]
It is easy to see that $H^i(F^\bullet) = H_{2n-i}(A, M)$ for $i \geq 0$. The terms of $F^\bullet$ are given by $F^0 = (I^n/I^{n+1}) \otimes_A M$ and $F^p = P_{2p-\bullet} \otimes_{A^e} M$ for $p > 0$. Therefore we obtain
\[ F^{2i} = M \otimes_A (I^{n-i}/I^{n-i+1}) \quad \text{and} \quad F^{2i-1} = \left((I^{n-i}/I^{n-i+1}) \otimes_A M\right) \otimes_{F^e} \Omega(F) \]
for $i > 0$. Consider the spectral sequence $E$ from corollary 2.6 associated with the complex $\mathcal{F}^\bullet$. Its first page is $E_1^{pq} = \lim^q F^p$, and $E \Rightarrow H_{2n-1}(A, M)$. The functor $\Omega(F)$ is an additive $O$-representation, where $O(F \to A) = F^e$ (see [1, 2.3]). Using proposition 3.7 and the previous lemma we get

$$E_1^{pq} = \lim^q F^p = \begin{cases} 0, & \text{if } p \neq 2(n-q) \text{ and } p \neq 0 \\ \lim^q (I^n/I^{n+1}) \otimes_A M, & \text{if } p = 0 \\ \Omega^p_{\text{inc}}(A) \otimes_A M, & \text{if } p = 2(n-q) > 0 \end{cases}$$

Since for any $i \leq n$ on the diagonal $p + q = i$ on $E_1$ all nonzero terms concentrated in the column $p = 0$ and equal to $\lim^i (I^n/I^{n+1}) \otimes_A M$, we obtain the required isomorphisms. □

7.3. Cyclic homology of augmented algebras.

**Lemma 7.8.** Let $A$ be an algebra. Then the following holds.

$$\lim^i F/I^2 = \begin{cases} k, & i = 0 \\ \bar{A}^2, & i = 1 \\ 0, & i > 1. \end{cases}$$

**Proof.** Note that $\Omega(F) \uparrow^A \cong \Omega(F)/(I\Omega(F) + \Omega(F)I)$ and the composition of the universal derivation and the projection $F \to \Omega(F) \to \Omega(F) \uparrow^A$ vanishes on $I^2$. Hence the universal derivation induces the map $\delta : F/I^2 \to \Omega(F) \uparrow^A$ so that $\delta[I/I^2]$ coincides with Magnus embedding $\delta : I/I^2 \to \Omega(F) \uparrow^A$. Then the commutative triangle

$$\begin{array}{ccc}
I/I^2 & \xrightarrow{\delta} & \Omega(F) \uparrow^A \\
\downarrow & & \downarrow \\
F/I^2 & \xrightarrow{\delta} & \Omega(F) \uparrow^A \\
\end{array}$$

and short exact sequences $I/I^2 \to \Omega(F) \uparrow^A \to \Omega(A)$, $I/I^2 \to F/I^2 \to A$ give an octahedron in the derived category $D^+(\text{Vect}_{k}^{\text{Pres}(A)})$:

$$\begin{array}{c}
I/I^2 \xrightarrow{\delta} I/I^2 \\
\downarrow \downarrow \downarrow \downarrow \\
\Omega^{[0,1]}(A) \xrightarrow{\delta} F/I^2 \xrightarrow{\delta} \Omega(F) \uparrow^A \xrightarrow{\delta} \Omega^{[0,1]}(A)[1] \\
\downarrow \downarrow \downarrow \downarrow \\
\Omega^{[0,1]}(A) \xrightarrow{\delta} A \xrightarrow{\delta} \Omega(A) \xrightarrow{\delta} \Omega^{[0,1]}(A)[1] \\
\downarrow \downarrow \downarrow \downarrow \\
I/I^2[1] \xrightarrow{\delta} I/I^2[1],
\end{array}$$

where $\Omega^{[0,1]}(A)$ is the complex $\cdots \to 0 \to A \xrightarrow{\delta} \Omega(A) \to 0 \to \cdots$. By lemma 7.3 we have $\lim^i \Omega(F) \uparrow^A = 0$, and hence $\text{Rlim} \Omega(F) \uparrow^A = 0$. Then, applying the total derived functor $\text{Rlim}$ to the distinguished triangle $\Omega^{[0,1]}(A) \to F/I^2 \to \Omega(F) \uparrow^A \to \Omega^{[0,1]}(A)[1]$, we obtain the
isomorphism \( \text{Rlim} F/I^2 \cong \Omega^{[0,1]}(A) \) in the derived category \( D^+(\text{Vect}_k) \). Since \( \ker(\delta) = k \) and \( \text{Coker}(\delta) = \hat{A} \otimes k \) (see (7.3)), we get the claimed statement.

\[ \square \]

\textbf{Lemma 7.9.} Let \( A \) be an algebra and \( n \geq 2 \). Then the unit homomorphism \( \eta_F : k \rightarrow F \) induces an isomorphism

\[ \lim F/I^n \cong k. \]  

\textbf{Proof.} The proof is by induction on \( n \). The base case is given by the previous lemma. The inductive step follows from the short exact sequence \( I^n/I^{n+1} \rightarrow F/I^{n+1} \rightarrow F/I^n \) and the fact that \( \lim F/I^n = \lim I^n/I^{n+1} = 0 \) for \( n \geq 2 \) (lemma 7.5). \( \square \)

An augmented algebra is a \( k \)-algebra together with an algebra homomorphism \( \varepsilon_A : A \rightarrow k \) called augmentation map. The augmentation map provides a natural structure of \( A \)-module on \( k \). The augmentation ideal is denoted by \( \Delta(A) := \ker(\varepsilon_A) \). The unit homomorphism \( \eta_A : k \rightarrow A \) and the augmentation map \( \varepsilon_A : A \rightarrow k \) give a natural decomposition \( A = k \oplus \Delta(A) \). If \( \pi : F \rightarrow A \) is a presentation of an augmented algebra, then the free algebra \( F \) has a natural augmentation map \( \varepsilon_F = \varepsilon_A \circ \pi \).

\textbf{Lemma 7.10.} Let \( A \) be an augmented algebra and \( n \geq 1 \). Then there are isomorphisms

\[ \lim^i \Delta(F) = 0, \quad \lim^i I^n = \lim^{i-1} \Delta(F)/I^n \]  

for all \( i \). In particular, \( \lim I^n = 0 \).

\textbf{Proof.} It is easy to see that \( \Delta(F) \cong \Omega(F) \otimes_F k \). Then the isomorphism \( \Omega(F_1 \ast F_2) \cong \Omega(F_1)^{(F_1 \ast F_2)^{n}} \otimes \Omega(F_2)^{(F_1 \ast F_2)^{n}} \) implies \( \Delta(F_1 \ast F_2) \cong \Delta(F_1)^{(F_1 \ast F_2)} + \Delta(F_2)^{(F_1 \ast F_2)} \). Hence the representation \( \Delta(F) \) is \( F \)-additive, and by proposition 3.7 \( \lim^i \Delta(F) = \lim^i F \otimes_F \Delta(F) = 0 \). This equality and the short exact sequence \( I^n \rightarrow \Delta(F) \rightarrow \Delta(F)/I^n \) imply that \( \lim^i I^n = \lim^{i-1} \Delta(F)/I^n \).

\[ \square \]

\textbf{Theorem 7.11.} Let \( A \) be an augmented algebra over a field \( k \) of characteristic 0. Then there are isomorphisms

\[ \HC_{2n}(A) \cong \lim F/(I^{n+1} + [F, F]), \]  

\[ \HC_{2n-1}(A) \cong \lim I^n/[I, I^n], \]  

\[ \HHC_{2n+1}(A) = \lim I^{n+1}/[I, I^n], \]  

\[ \HHC_{2n}(A) = \lim I^{n+1}/[I, I^n], \]

\textbf{Remark 7.12.} The first and the third isomorphism was proved by Quillen but we prove it for completeness.

\textbf{Proof.} First of all, we prove that \( \lim^i H_1(F/I^n) = 0 \) for \( i = 0, 1 \). Consider the natural projection \( p_F : F/I^n \rightarrow F/(I^n + [F, F]) \). The unit homomorphism \( \eta_F : k \rightarrow F \) induces the map \( \tilde{\eta} : k \rightarrow F/I^n \), the augmentation map \( \varepsilon_F : F \rightarrow k \) induces the map \( \tilde{\varepsilon} : (F/I^n)_2 \rightarrow k \) and the equation \( \tilde{\varepsilon} \circ p_F \circ \tilde{\eta} = \text{id}_k \) holds. Then we obtain the equation
\[\lim(\xi) \circ \lim(p_F) \circ \lim(\eta) = \text{id},\] and hence \(\lim(p_F) : \lim F/I^n \cong k \rightarrow \lim (F/I^n)_2\) is a monomorphism. Divide the exact sequence

\[(7.14) \quad 0 \rightarrow H_1(F, F/I^n) \rightarrow \Omega(F) \otimes_{F^e} (F/I^n) \rightarrow F/I^n \xrightarrow{p_F} (F/I^n)_2 \rightarrow 0\]

into two short exact sequences \(\mathcal{S} \rightarrow F/I^n \rightarrow (F/I^n)_2\) and \(H_1(F, F/I^n) \rightarrow \Omega(F) \otimes_{F^e} (F/I^n) \rightarrow \mathcal{S}\), where \(\mathcal{S}\) is some representation of \(\text{Pres}(A)\). Since \(\lim p_F : \lim F/I^n \rightarrow \lim (F/I^n)_2\) is a monomorphism, the first short exact sequence show that \(\lim \mathcal{S} = 0\). By lemma \(7.3\) we get \(\lim^i \Omega(F) \otimes_{F^e} (F/I^n) = 0\) for all \(i\). These equalities and the second short exact sequence imply that \(\lim^i H_1(F, F/I^n) = 0\) for \(i = 0, 1\).

Consider the Quillen’s exact sequence \((4.8)\)

\[(7.15) \quad 0 \rightarrow HC_{2n}(A) \rightarrow (F/I^{n+1})_2 \rightarrow H_1(F, F/I^n)_{\sigma} \rightarrow HC_{2n-1}(A) \rightarrow 0\]

and divide it into two short exact sequences \(\mathcal{T} \rightarrow H_1(F, F/I^n)_{\sigma} \rightarrow HC_{2n-1}(A)\) and \(HC_{2n}(A) \rightarrow (F/I^{n+1})_2 \rightarrow H_1(F, F/I^n)_{\sigma}\). Since the field \(k\) is of characteristic 0, the vector space \(H_1(F, F/I^n)_{\sigma}\) is a functorial direct summand of \(H_1(F, F/I^n)\). It follows that \(\lim^i H_1(F, F/I^n)_{\sigma} = 0\) for \(i \in \{0, 1, \}\), and hence, \(\lim \mathcal{T} = 0\) and \(\lim^1 \mathcal{T} = HC_{2n-1}(A)\). Using these isomorphisms, the second short exact sequence and the equality \(\lim^1 HC_{2n}(A) = 0\), we obtain \(HC_{2n}(A) = \lim F/(I^{n+1} + [F, F])\) and \(HC_{2n-1}(A) = \lim^1 F/(I^{n+1} + [F, F])\).

By the similar argument the exact sequence

\[(7.16) \quad 0 \rightarrow H_1(F, I^n) \rightarrow \Omega(F) \otimes_{F^e} I^n \rightarrow I^n \rightarrow (I^n)^2 \rightarrow 0\]

and isomorphisms \(\lim I^n = 0\) (lemma \(7.10\)) imply \(\lim^i H_1(F, I^n) = 0\) for \(i \in \{0, 1\}\). Finally, using the second Quillen’s sequence \((4.9)\), one can similarly prove the rest two isomorphisms.

**Corollary 7.13.** Let \(A\) be a commutative algebra of finite type over \(\mathbb{C}\). Then there are isomorphisms

\[(7.17) \quad HC_{2n}(A) = \lim F/(I^{n+1} + [F, F]),\]

\[(7.18) \quad HC_{2n-1}(A) = \lim^1 F/(I^{n+1} + [F, F]).\]

\[(7.19) \quad HC_{2n-1}(A) = \lim I^{n+1}/[I, I^n]\]

\[(7.20) \quad HC_{2n}(A) = \lim^1 I^{n+1}/[I, I^n].\]

**Proof.** The isomorphisms \((7.17)\) and \((7.19)\) are proved by Quillen. The others follow from the previous theorem and the fact that any maximal ideal \(m \triangleleft A\) gives an augmentation \(A \rightarrow A/m \cong \mathbb{C}\).

8. Derived functors in the sense of Dold-Puppe as higher limits

Let \(T\) be an endofunctor on the category of abelian groups. The family \(L_iT(-)\) of derived functors, in the sense of Dold-Puppe \(3\), of \(T\) are defined by

\[L_iT(A) = \pi_iTN^{-1}P_*, \quad i \geq 0, \ A \in \text{abelian groups},\]
where $P_* \to A$ is a projective resolution of $A$, and $N^{-1}$ is the Dold-Kan transform, which is the the inverse of the Moore normalization functor

$$N : S(\text{abelian groups}) \to Ch(\text{abelian groups})$$

from the category of simplicial abelian groups to the category of chain complexes (see, for example [15], Section 8.4).

We will use the standard notation of the tensor, symmetric, exterior and divided powers:

$$\otimes^n, S^n, \Lambda^n, \Gamma^n : \text{abelian groups} \to \text{abelian groups}, \quad n \geq 1$$

For an abelian group $A$, we consider the category $\text{Pres}(A)$ of presentations $H \hookrightarrow F \twoheadrightarrow A$ with a free abelian group $F$.

**Theorem 8.1.** For $n \geq 1$ and $i \geq 0$, there are natural isomorphisms

$$\lim_{\leftarrow}^i \Lambda^n(H) = L_{n-i}S^n(A) \quad (8.1)$$

$$\lim_{\leftarrow}^i \Gamma^n(H) = L_{n-i}A^n(A) \quad (8.2)$$

$$\lim_{\leftarrow}^i \otimes^n(H) = L_{n-i} \otimes^n(A) \quad (8.3)$$

where the derived limits are taken over the category $\text{Pres}(A)$.

**Lemma 8.2.** Let $F, G$ be functors in the category of abelian groups, which can be presented as tensor products of certain symmetric, exterior and divided powers. Then, for any $i \geq 0$,

$$\lim_{\leftarrow}^i (F(H) \otimes G(F)) = 0.$$

**Proof.** The functors $F(H) \otimes G(F)$ are monoadditive, therefore, the statement follows for $i = 0$. Observe that the cokernel of the natural map

$$(F(H) \otimes G(F))^2 \hookrightarrow F(H \oplus F) \otimes G(F \oplus F)$$

also can be presented as a directs sum of functors of the type considered in lemma. The statement now follows by induction on $i$, using proposition 3.1. \qed

**Proof of theorem 8.1.** Given an element

$$0 \to H \to F \to A \to 0$$

of $\text{Ext}(A)$, the Koszul complexes

$$Kos(H \to F) : 0 \to \Lambda^n(H) \to \Lambda^{n-1}(H) \otimes F \to \cdots \to H \otimes S^{n-1}(F) \to S^n(F) \quad (8.4)$$

and

$$Kos'(H \to F) : 0 \to \Gamma^n(H) \to \Gamma^{n-1}(H) \otimes F \to \cdots \to H \otimes A^{n-1}(F) \to A^n(F) \quad (8.5)$$

represent models of the objects $LS^n(A)$ and $L\Lambda^n(A)$ in the derived category (see [7], Proposition 2.4 and Remark 2.7). Here the maps between the terms of Koszul complexes are standard. In particular, there are natural isomorphism

$$L_iSP^n(A) = H_i(Kos(H \to F)), \quad L_i\Lambda^n(A) = H_i(Kos'(H \to F)).$$

Observe that, for any polynomial functor $F$, such that $F(0) = 0$, $\lim_{\leftarrow}^i F(F) = 0$. This follows by induction on $i$, using proposition 3.1. The isomorphisms (8.1) and (8.2) follow from lemma 8.2 and corollary 2.6.
It turns out from the Eilenberg-Zilber theorem that the derived functors of the $n$-th tensor power can be described as

$$L_i \otimes^n (A) = H_i\left( A \otimes \cdots \otimes A \right) = H_i((H \to F)^{\otimes n}), \quad 0 \leq i \leq n-1.$$ 

Now observe that, all terms of the complex $(H \to F)^{\otimes n}$ in degrees $0 < i < n$ are direct sums of the functors from lemma 8.2 and hence

$$\lim_{\leftarrow}^j (\left( H \to F \right)^{\otimes n})_i = 0, \quad j \geq 0, \quad 0 < i < n.$$ 

Applying proposition 3.1, we also get

$$\lim_{\leftarrow}^j (\left( H \to F \right)^{\otimes n})_0 = \lim_{\leftarrow}^j \otimes^n (F) = 0, \quad j \geq 0.$$ 

The isomorphism (8.3) follows from corollary 2.6 applied to the complex $(H \to F)^{\otimes n}$. □

Recall that, for an abelian group $H$, there are natural isomorphisms

$$L_n S^n(H, 1) = \Lambda^n(H), \quad L_n \Lambda^n(H, 1) = \Gamma^n(H), \quad L_n \otimes^n (H, 1) = \otimes^n(H).$$

Therefore, the formulas (8.1)-(8.3) can be written as

$$(8.6) \quad \lim_{\leftarrow}^i L_n F(H, 1) = L_{n-i} F(A)$$

where $F = S^n, \Lambda^n, \otimes^n$. It is natural to conjecture that the formulas like (8.6) take place for more general class of polynomial functors of degree $n$, for example, for strictly $n$-polynomial functors. It is easy to show using the above methods that (8.6) is true for iterated tensor products of symmetric and exterior powers.
