COMMUNITY DETECTION IN THE SPARSE HYPERGRAPH STOCHASTIC BLOCK MODEL

SOUMIK PAL AND YIZHE ZHU

Abstract. We consider the community detection problem in sparse random hypergraphs. Angelini et al. in [6] conjectured the existence of a sharp threshold on model parameters for community detection in sparse hypergraphs generated by a hypergraph stochastic block model. We solve the positive part of the conjecture for the case of two blocks: above the threshold, there is a spectral algorithm which asymptotically almost surely constructs a partition of the hypergraph correlated with the true partition. Our method is a generalization to random hypergraphs of the method developed by Massoulié in [32] for sparse random graphs.

1. Introduction

Clustering is an important topic in network analysis, machine learning, and computer vision [24]. Many clustering algorithms are based on graphs, which represent pairwise relationships among data. Hypergraphs can be used to represent higher-order relationships among objects, including co-authorship and citation networks, and they have been shown empirically to have advantages over graphs [40]. Recently hypergraphs have been used as the data model in machine learning, including recommender system [38], image retrieval [30, 5] and bioinformatics [39]. The stochastic block model (SBM) is a generative model for random graphs with community structures, which serves as a useful benchmark for clustering algorithms on graph data. It is natural to have an analogous model for random hypergraphs to model higher-order relations. In this paper, we consider a higher-order SBM called the hypergraph stochastic block model (HSBM). Before describing HSBMs, let’s recall clustering on graph SBMs.

1.1. The Stochastic block model for graphs. In this section, we summarize the state-of-the-art results for graph SBM with two blocks of roughly equal size. Let $\Sigma_n$ be the set of all pairs $(G, \sigma)$, where $G = ([n], E)$ is a graph with vertex set $[n]$ and edge set $E$, $\sigma = (\sigma_1, \ldots, \sigma_n) \in \{+1, -1\}^n$ are spins on $[n]$, i.e., each vertex $i \in [n]$ is assigned with a spin $\sigma_i \in \{-1, +1\}$. From this finite set $\Sigma_n$, one can generate a random element $(G, \sigma)$ in two steps.

1. First generate i.i.d random variables $\sigma_i \in \{-1, +1\}$ equally likely for all $i \in [n]$.
2. Then given $\sigma = (\sigma_1, \ldots, \sigma_n)$, we generate a random graph $G$ where each edge $\{i, j\}$ is included independently with probability $p$ if $\sigma_i = \sigma_j$ and with probability $q$ if $\sigma_i \neq \sigma_j$.

The law of this pair $(G, \sigma)$ will be denoted by $G(n, p, q)$. In particular, we are interested in the model $G(n, p_n, q_n)$ where $p_n, q_n$ are parameters depending on $n$. We use the shorthand notation $P_{\sigma_n}$ to emphasize that the integration is taken under the law $G(n, p_n, q_n).

Imagine $C_1 = \{i : \sigma_i = +1\}$ and $C_2 = \{i : \sigma_i = -1\}$ as two communities in the graph $G$. Observing only $G$ from a sample $(G, \sigma)$ from the distribution $G(n, p_n, q_n)$, the goal of community detection is to estimate the unknown vector $\sigma$ up to a sign flip. Namely, we construct label estimators $\hat{\sigma}_i \in \{\pm 1\}$ for each $i$ and consider the empirical overlap between $\hat{\sigma}$ and unknown $\sigma$ defined by

$$ov_n(\hat{\sigma}, \sigma) := \frac{1}{n} \sum_{i \in [n]} \sigma_i \hat{\sigma}_i.$$

We may ask the following questions about the estimation as $n$ tends to infinity:

(1) Exact recovery (strong consistency):
\[
\lim_{n \to \infty} P_{\hat{G}_n}(\{ov_n(\hat{\sigma}, \sigma) = 1\} \cup \{ov_n(\hat{\sigma}, \sigma) = -1\}) = 1.
\]

(2) Almost exact recovery (weak consistency): for any \(\epsilon > 0\),
\[
\lim_{n \to \infty} P_{\hat{G}_n}(\{|ov_n(\hat{\sigma}, \sigma) - 1| > \epsilon\} \cap \{|ov_n(\hat{\sigma}, \sigma) + 1| > \epsilon\}) = 0.
\]

(3) Detection: Find a partition which is correlated with the true partition. More precisely, there exists a constant \(r > 0\) such that it satisfies the following: for any \(\epsilon > 0\),
\[
\lim_{n \to \infty} P_{\hat{G}_n}(\{|ov(\hat{\sigma}, \sigma) - r| > \epsilon\} \cap \{|ov(\hat{\sigma}, \sigma) + r| > \epsilon\}) = 0.
\]

There are many works on these questions using different tools, we list some of them. A conjecture of [14] based on non-rigorous ideas from statistical physics predicts a threshold of detection in the SBM, which is called the Kesten-Stigum threshold. In particular, if \(p_n = \frac{a}{n}\) and \(q_n = \frac{b}{n}\) where \(a, b\) are positive constants independent of \(n\), then the detection is possible if and only if \((a - b)^2 > 2(a + b)\). This conjecture was confirmed in [33, 35, 32, 8] where [35, 32, 8] provided efficient algorithms to achieve the threshold. Very recently, two alternative spectral algorithms were proposed based on distance matrices [36] and a graph powering method in [3], and they both achieved the detection threshold.

Suppose \(p_n = \frac{a \log n}{n}, q_n = \frac{b \log n}{n}\) where \(a, b\) are constant independent of \(n\). Then the exact recovery is possible if and only if \((\sqrt{a} - \sqrt{b})^2 > 2\), which was solved in [2, 23] with efficient algorithms achieving the threshold. Besides the phase transition behavior, various algorithms were proposed and analyzed in different regimes and more general settings beyond the 2-block SBM [10, 11, 22, 4, 28, 34, 13, 37, 7], including spectral methods, semidefinite programming, belief-propagation, and approximate message-passing algorithms. We recommend [1] for further details.

1.2. Hypergraph stochastic block models. The hypergraph stochastic block model (HSBM) is a generalization of the SBM for graphs, which was first studied in [18], where the authors consider hypergraphs generated by the stochastic block models that are dense and uniform. A faithful representation of a hypergraph is its adjacency tensor (see Definition 2.2). However, most of the computations involving tensors are not the same.

For detection of the HSBM with two blocks, the authors of [6] proposed a conjecture that the phase transition occurs in the regime of logarithmic average degrees in [29, 12, 11] and the exact threshold was given in [27], by a generalization of the techniques in [2]. Almost exact recovery for HSBMs was studied in [11, 12, 21].

For detection of the HSBM with two blocks, the authors of [6] proposed a conjecture that the phase transition occurs in the regime of constant average degree, based on the performance of the belief-propagation algorithm. Also, they conjectured a spectral algorithm based on non-backtracking operators on hypergraphs could reach the threshold. In [17], the authors showed an algorithm for detection when the average degree is bigger than some constant by reducing it to a bipartite stochastic block model. They also mentioned a barrier to further improvement. We confirm the positive part of the conjecture in [6] for the case of two blocks: above the threshold, there is a spectral algorithm which asymptotically almost surely constructs a partition of the hypergraph correlated with the true partition.

Now we specify our \(d\)-uniform hypergraph stochastic block model with two clusters. Analogous to \(\mathcal{G}(n, p_n, q_n)\), we define \(\mathcal{H}(n, d, p_n, q_n)\) for \(d\)-uniform hypergraphs. Let \(\Sigma_n\) be the set of all pair \((H, \sigma)\), where \(H = ([n], E)\) is a \(d\)-uniform hypergraph (see Definition 2.1 below) with vertex set \([n]\) and hyperedge set \(E\), \(\sigma = (\sigma_1, \ldots, \sigma_n) \in \{+1, -1\}^n\) are the spins on \([n]\). From this finite set \(\Sigma_n\), one can generate a random element \((H, \sigma)\) in two steps:

(1) First generate i.i.d random variables \(\sigma_i \in \{-1, +1\}\) equally likely for all \(i \in [n]\).

(2) Then given \(\sigma = (\sigma_1, \ldots, \sigma_n)\), we generate a random hypergraph \(H\) where each hyperedge \(\{i_1, \ldots, i_d\}\) is included independently with probability \(p_n\) if \(\sigma_{i_1} = \cdots = \sigma_{i_d}\) and with probability \(q_n\) if the spins \(\sigma_{i_1}, \ldots, \sigma_{i_d}\) are not the same.

The law of this pair \((H, \sigma)\) will be denoted by \(\mathcal{H}(n, d, p_n, q_n)\). We use the shorthand notation \(\mathbb{P}_{\mathcal{H}_n}\) and \(\mathbb{E}_{\mathcal{H}_n}\) to emphasize that integration is taken under the law \(\mathcal{H}(n, d, p_n, q_n)\). Often we drop the index \(n\) from our notation, but it will be clear from \(\mathbb{P}_{\mathcal{H}_n}\).
1.3. Main results. We consider the detection problem of the HSBM in the constant expected degree regime. Let
\[ p_n := \frac{a}{\binom{n}{d-1}}, \quad q_n := \frac{b}{\binom{n}{d-1}}, \]
for some constants \( a \geq b > 0 \) and a constant integer \( d \geq 3 \). Let
\[ \alpha := (d-1)\frac{a}{2d-1}, \quad \beta := (d-1)\frac{a-b}{2d-1}. \]
(1.3)

Here \( \alpha \) is a constant which measures the expected degree of any vertex, and \( \beta \) measures the discrepancy between the number of neighbors with + sign and − sign of any vertex. For \( d = 2 \), \( \alpha, \beta \) are the same parameters for the graph case in [32]. Now we are able to state our main result which is an extension of the result of for graph SBMs in [32]. Note that with the definition of \( \alpha, \beta \), we have \( \alpha > \beta \). The condition \( \beta^2 > \alpha \) in the statement of Theorem (1.1) below implies \( \alpha, \beta > 1 \), which will be assumed for the rest of the paper.

**Theorem 1.1.** Assume \( \beta^2 > \alpha \). Let \((H, \sigma)\) be a random labeled hypergraph sampled from \( \mathcal{H}(n, d, p_n, q_n) \) and \( B^{(l)} \) be its \( l \)-th self-avoiding matrix (see Definition 2.6 below). Set \( l = c \log(n) \) for a constant \( c \) such that \( c \log(\alpha) < 1/8 \). Let \( x \) be a \( l_2 \)-normalized eigenvector corresponding to the second largest eigenvalue of \( B^{(l)} \).

There exists a constant \( t \) such that, if we define the label estimator \( \hat{\sigma}_i \) as
\[
\hat{\sigma}_i = \begin{cases} 
+1 & \text{if } x_i \geq t/\sqrt{n}, \\
-1 & \text{otherwise},
\end{cases}
\]
then detection is possible. More precisely, there exists a constant \( r > 0 \) such that the empirical overlap between \( \hat{\sigma} \) and \( \sigma \) defined similar to (1.1) satisfies the following: for any \( \varepsilon > 0 \),
\[
\lim_{n \to \infty} \mathbb{P}_{H_n} \left( \{|\text{ov}_n(\hat{\sigma}, \sigma) - r| > \varepsilon\} \cap \{|\text{ov}_n(\hat{\sigma}, \sigma) + r| > \varepsilon\} \right) = 0.
\]

**Remark 1.2.** If we take \( d = 2 \), the condition \( \beta^2 > \alpha \) is the threshold for detection in graph SBMs proved in [32, 33, 35]. When \( d \geq 3 \), the conjectured detection threshold for HSBMs is given in Equation (48) of [6]. With our notations, in the 2-block case, Equation (48) in [6] can be written as \( \frac{\alpha-\beta}{\alpha+\beta} = \sqrt{\frac{\alpha-1}{\alpha+1}} \), which says \( \beta^2 = \alpha \) is the conjectured detection threshold for HSBMs. This is an analog of the Kesten-Stigum threshold proved in the graph case [14, 35, 32, 8]. Our Theorem 1.1 proves the positive part of the conjecture.

Our algorithm can be summarized in two steps. The first step is a dimension reduction: \( B^{(l)} \) has \( n^2 \) many entries from the original adjacency tensor \( T \) (see Definition 2.2) of \( n^d \) many entries. Since the \( l \)-neighborhood of any vertex contains at most one cycle with high probability (see Lemma 4.4), by breadth-first search, the matrix \( B^{(l)} \) can be constructed in polynomial time. The second step is a simple spectral clustering according to leading eigenvectors as the common clustering algorithm in the graph case.

Unlike graph SBMs, in the HSBMs, the random hypergraph \( H \) we observe is essentially a random tensor. Getting the spectral information of a tensor is NP-hard [25] in general, making the corresponding problems in HSBMs very different from graph SBMs. It is not immediately clear which operator to associate to \( H \) that encodes the community structure in the bounded expected degree regime. The novelty of our method is a
way to project the random tensor into matrix forms (the self-avoiding matrix $B^{(l)}$ and the adjacency matrix $A$) that give us the community structure from their leading eigenvectors. In practice, the hypergraphs we observed are usually not $d$-uniform, which can not be represented as a tensor. However, we can still construct the matrix $B^{(l)}$ since the definition of self-avoiding walks does not depend on the uniformity assumption. In this paper, we focus on the $d$-uniform case to simplify the presentation, but our proof techniques can be applied to the non-uniform case.

The analysis of HSBMs is harder than the original graph SBMs due to the extra dependency in the hypergraph structure and the lack of linear algebra tools for tensors. To overcome these difficulties, new techniques are developed in this paper to establish the desired results.

There are multiple ways to define self-avoiding walks on hypergraphs, and our definition (see Definition 2.4) is the only one that works for us when applying the moment method. We develop a moment method suitable for sparse random hypergraphs in Section 7 that controls the spectral norms by counting concatenations of self-avoiding walks on hypergraphs. The combinatorial counting argument in the proof of Lemma 7.1 is more involved as we need to consider labeled vertices and labeled hyperedges. The moment method for hypergraphs developed here could be of independent interest for other random hypergraph problems.

The growth control of the size of the local neighborhood (Section 4) for HSBMs turns out to be more challenging compared to graph SBMs in [32] due to the dependency between the number of vertices with spin $+$ and $-$, and overlaps between different hyperedges. We use a new second-moment estimate to obtain a matching lower bound and upper bound for the size of the neighborhoods in the proof of Theorem 8.4. The issues mentioned above do not appear in the sparse random graph case.

To analyze the local structure of HSBMs, we prove a new coupling result between a typical neighborhood of a vertex in the sparse random hypergraph $H$ and a multi-type Galton-Watson hypertree described in Section 5, which is a stronger version of local weak convergence of sparse random hypergraphs (local weak convergence for hypergraphs was recently introduced in [15]). Compared to the classical 2-type Galton-Watson tree in the graph case, the vertex $\pm$ labels in a hyperedge is not assigned independently. We carefully designed the probability of different types of hyperedges that appear in the hypertree to match the local structure of the HSBM. Combining all the new ingredients, we obtain the weak Ramanujan property of $B^{(l)}$ for sparse HSBMs in Theorem 6.1 as a generalization of the results in [32]. We conclude the proof of our Theorem 1.1 in Section 6.

Our Theorem 1.1 deals with the positive part of the phase transition conjecture in [6]. To have a complete characterization of the phase transition, one needs to show an impossibility result when $\beta^2 < \alpha$. Namely, below this threshold, no algorithms (even with exponential running time) will solve the detection problem with high probability. For graph SBMs, the impossibility result was proved in [33] based on a reduction to the broadcasting problem on Galton-Watson trees analyzed in [16]. To answer the corresponding problem in the HSBMs, one needs to establish a similar information-theoretical lower bound for the broadcasting problem on hypertrees and relate the problem to the detection problem on HSBMs. To the best of our knowledge, even for the very first step, the broadcasting problem on hypertrees has not been studied yet. The multi-type Galton-Watson hypertrees described in Section 5 can be used as a model to study this type of problem on hypergraphs. We leave it as a future direction.

2. Preliminaries

**Definition 2.1** (hypergraph). A hypergraph $H$ is a pair $H = (V, E)$ where $V$ is a set of vertices and $E$ is the set of non-empty subsets of $V$ called hyperedges. If any hyperedge $e \in E$ is a set of $d$ elements of $V$, we call $H$ $d$-uniform. In particular, 2-uniform hypergraph is an ordinary graph. A $d$-uniform hypergraph is complete if any set of $d$ vertices is a hyperedge and we denote a complete $d$-uniform hypergraph on $[n]$ by $K_{n,d}$. The degree of a vertex $i \in V$ is the number of hyperedges in $H$ that contains $i$.

**Definition 2.2** (adjacency tensor). Let $H = (V, E)$ be a $d$-uniform hypergraph with $V = [n]$. We define $T$ to be the adjacency tensor of $H$ such that for any set of vertices $\{i_1, i_2, \ldots, i_d\}$,

$$T_{i_1, \ldots, i_d} = \begin{cases} 1 & \text{if } \{i_1, \ldots, i_d\} \in E, \\ 0 & \text{otherwise}. \end{cases}$$
We set $T_{\sigma(i_1), \sigma(i_2), \ldots, \sigma(i_d)} = T_{i_1, \ldots, i_d}$ for any permutation $\sigma$. We may write $T_e$ in place of $T_{i_1, \ldots, i_d}$ where $e = \{i_1, \ldots, i_d\}$.

**Definition 2.3** (adjacency matrix). The adjacency matrix $A$ of a $d$-uniform hypergraph $H = (V, E)$ with vertex set $[n]$ is a $n \times n$ symmetric matrix such that for any $i \neq j$, $A_{ij}$ is the number of hyperedges in $E$ which contains $i, j$ and $A_{ii} = 0$ for $i \in [n]$. Equivalently, we have

$$A_{ij} = \begin{cases} \sum_{e: (i, j) \in e} T_e & \text{if } i \neq j, \\ 0 & \text{if } i = j. \end{cases}$$

**Definition 2.4** (walk). A walk of length $l$ on a hypergraph $H$ is a sequence $(i_0, e_1, i_1, \ldots, e_l, i_l)$ such that $i_{j-1} \neq i_j$ and $\{i_{j-1}, i_j\} \subseteq e_j$ for all $1 \leq j \leq l$. A walk is closed if $i_0 = i_l$ and we call it a circuit. A self-avoiding walk of length $l$ is a walk $(i_0, e_1, i_1, \ldots, e_l, i_l)$ such that

1. $|\{i_0, i_1, \ldots, i_l\}| = l + 1$.
2. Any consecutive hyperedges $e_{j-1}, e_j$ satisfy $e_{j-1} \cap e_j = \{i_{j-1}\}$ for $2 \leq j \leq l$.
3. Any two hyperedges $e_j, e_k$ with $1 \leq j < k \leq l, k \neq j + 1$ satisfy $e_j \cap e_k = \emptyset$.

See Figure 2 for an example of a self-avoiding walk in a 3-uniform hypergraph. Recall that a self-avoiding walk of length $l$ on a graph is a walk $(i_0, \ldots, i_l)$ without repeated vertices. Our definition is a generalization of the self-avoiding walks to hypergraphs.

**Definition 2.5** (cycle and hypertree). A cycle of length $l$ with $l \geq 2$ in a hypergraph $H$ is a walk $(i_0, e_1, i_1, \ldots, i_{l-1}, e_l, i_0)$ such that $i_0, \ldots, i_{l-1}$ are distinct vertices and $e_1, \ldots, e_l$ are distinct hyperedges. A hypertree is a hypergraph which contains no cycles.

Let $\binom{[n]}{d}$ be the collection of all subsets of $[n]$ with size $d$. For any subset $e \in \binom{[n]}{d}$ and $i \neq j \in [n]$, we define

$$A^e_{ij} = \begin{cases} 1 & \text{if } \{i, j\} \in e \text{ and } e \in E, \\ 0 & \text{otherwise,} \end{cases}$$

and we define $A^e_{ii} = 0$ for all $i \in [n]$. With our notation above, $A_{ij} = \sum_{e \in \binom{[n]}{d}} A^e_{ij}$. We have the following expansion of the trace of $A^k$ for any integer $k \geq 0$:

$$\text{tr}A^k = \sum_{i_0, i_2, \ldots, i_{k-1} \in [n]} A^e_{i_0 i_1} A^e_{i_2 i_3} \cdots A^e_{i_{k-1} i_0} = \sum_{i_0, i_1, \ldots, i_{k-1} \in [n]} A^e_{i_0 i_1} \cdots A^e_{i_{k-2} i_{k-1}} A^e_{i_{k-1} i_0}.$$
$B^{(l)}$ is a symmetric matrix since a time-reversing self avoiding walk from $i$ to $j$ is a self avoiding walk from $j$ to $i$. Let $\text{SAW}_{ij}$ be the set of all self-avoiding walks of length $l$ connecting $i$ and $j$ in the complete $d$-uniform hypergraph on vertex set $[n]$. We denote a walk of length $l$ by $w = (i_0, e_{i_1}, \ldots, i_{l-1}, e_{i_l}, i_l)$. Then for any $i, j \in [n]$,

$$B^{(l)}_{ij} = \sum_{w \in \text{SAW}_{ij}} \prod_{t=1}^{l} A^{e_{i_t}}_{i_{t-1}i_t}. \tag{2.1}$$

3. Matrix expansion and spectral norm bounds

Consider a random labeled $d$-uniform hypergraph $H$ sampled from $\mathcal{H}(n,d,p_n,q_n)$ with adjacency matrix $A$ and self-avoiding matrix $B^{(l)}$. Let $\overline{A} := \mathbb{E}_{\mathcal{H}_n}[A | B]$. Let $\rho(A) := \sup_{\|x\|_2 = 1} \|Ax\|_2$ be the spectral norm of a matrix $A$. Recall (2.1), define

$$\Delta^{(l)}_{ij} := \sum_{w \in \text{SAW}_{ij}} \prod_{t=1}^{l} (A^{e_{i_t}}_{i_{t-1}i_t} - \overline{A}^{e_{i_t}}_{i_{t-1}i_t}), \tag{2.3}$$

where $\overline{A}^{e_{i_t}}_{i_{t-1}i_t} = \mathbb{E}_{\mathcal{H}_n}[A^{e_{i_t}}_{i_{t-1}i_t} | B]$. $\Delta^{(l)}$ can be regarded as a centered version of $B^{(l)}$. We will apply the classical moment method to estimate the spectral norm of $\Delta^{(l)}$, since this method works well for centered random variables. Then we can relate the spectrum of $\Delta^{(l)}$ to the spectrum of $B^{(l)}$ through a matrix expansion formula which connects $\overline{A}$, $B^{(l)}$ and $\Delta^{(l)}$ in the following theorem. Recall the definition of $\alpha$ in (1.3).

**Theorem 3.1.** Let $H$ be a random hypergraph sampled from $\mathcal{H}(n,d,p_n,q_n)$ and $B^{(l)}$ be its $l$-th self avoiding matrix. Then the following holds.

1. There exist some matrices $\{\Gamma^{(l,m)}\}_{m=1}^{l}$ such that for any $l \geq 1$, $B^{(l)}$ satisfies the identity

$$B^{(l)} = \Delta^{(l)} + \sum_{m=1}^{l} (\Delta^{(l-m)}\overline{A}B^{(m-1)}) - \sum_{m=1}^{l} \Gamma^{(l,m)}. \tag{3.2}$$

2. For any sequence $l_n = O(\log n)$ and any fixed $\varepsilon > 0$,

$$\lim_{n \to \infty} \mathbb{P}_{\mathcal{H}_n} \left( \rho(\Delta^{(l_n)}) \leq n^{\varepsilon} \alpha^{(l_n)/2} \right) = 1, \tag{3.3}$$

$$\lim_{n \to \infty} \mathbb{P}_{\mathcal{H}_n} \left( \bigcap_{m=1}^{l_n} \left\{ \rho(\Gamma^{(l_n,m)}) \leq n^{\varepsilon-1} \alpha^{(l_n+m)/2} \right\} \right) = 1. \tag{3.4}$$

Theorem 3.1 is one of the main ingredients to show $B^{(l)}$ has a spectral gap. Together with the local analysis in Section 4, we will show in Theorem 6.1 that the bulk eigenvalues of $B^{(l)}$ are separated from the first and second eigenvalues. The proof of Theorem 3.1 is deferred to Section 7. The matrices $\{\Gamma^{(l,m)}\}_{m=1}^{l}$ in Theorem 3.1 record concatenations of self-avoiding walks with different weights, which will be carefully analyzed in Lemma 7.2 of Section 7.

4. Local analysis

In this section, we study the structure of the local neighborhoods in the HSBM. Namely, what the neighborhood of a typical vertex in the random hypergraph looks like.

**Definition 4.1.** In a hypergraph $H$, we define the distance $d(i, j)$ between two vertices $i, j$ to be the minimal length of walks between $i$ and $j$. Define the $t$-neighborhood $V_t(i)$ of a fixed vertex $i$ to be the set of vertices which have distance $t$ from $i$. Define $V_{\leq t}(i) := \bigcup_{k \leq t} V_k(i)$ to be the set all of vertices which have distance at most $t$ from $i$ and $V_{> t} = [n] \setminus V_{\leq t}$. Let $V^\pm_t(i)$ be the vertices in $V_t(i)$ with spin $\pm$ and define it similarly for $V^\pm_{\leq t}(i)$.
For \( i \in [n] \), define
\[
S_t(i) := |V_t(i)|, \quad D_t(i) := \sum_{j:d(i,j)=t} \sigma_j.
\]

Let \( \mathbf{1} = (1, \ldots, 1) \in \mathbb{R}^n \) and recall \( \sigma \in \{-1, 1\}^n \). We will show that when \( l = c \log n \) with \( c \log \alpha < 1/8 \), \( S_t(i), D_t(i) \) are close to the corresponding quantities \((B^{(l)}\mathbf{1})_i, (B^{(l)}\sigma)_i\) (see Lemma 11.1). In particular, the vector \((D_t(i))_{1 \leq t \leq n}\) is asymptotically aligned with the second eigenvector of \( B^{(l)} \), from which we get the information on the partitions. We give the following growth estimates of \( S_t(i) \) and \( D_t(i) \). The proof of Theorem 4.2 is given in Section 8.

**Theorem 4.2.** Assume \( \beta^2 > \alpha > 1 \) and \( l = c \log n \), for a constant \( c \) such that \( c \log \alpha < 1/4 \). There exists constants \( C, \gamma > 0 \) such that for sufficiently large \( n \), with probability at least \( 1 - O(n^{-\gamma}) \) the following holds for all \( i \in [n] \) and \( 1 \leq t \leq l \):

\[
(4.1) \quad S_t(i) \leq C \log(n) \alpha^t,
\]
\[
(4.2) \quad |D_t(i)| \leq C \log(n) \beta^t;
\]
\[
(4.3) \quad S_t(i) = \alpha^{t-1} S_t(i) + O(\log(n) \alpha^{t/2}),
\]
\[
(4.4) \quad D_t(i) = \beta^{t-1} D_t(i) + O(\log(n) \alpha^{t/2}).
\]

The approximate independence of neighborhoods of distinct vertices is given in the following lemma. It will be used later to analyze the martingales constructed on the Galton-Watson hypertree defined in Section 5. The proof of Lemma 4.3 is given in Appendix A.1.

**Lemma 4.3.** For any two fixed vertices \( i \neq j \), let \( l = c \log(n) \) with constant \( c \log(\alpha) < 1/4 \). Then the total variation distance between the joint law \( \mathcal{L}((U_k^\pm(i))_{k \leq l}, (U_k^\pm(j))_{k \leq l}) \) and the law with the same marginals and independence between them, denoted by \( \mathcal{L}((U_k^\pm(i))_{k \leq l} \otimes (U_k^\pm(j))_{k \leq l}) \), is \( O(n^{-\gamma}) \) for some \( \gamma > 0 \).

Now we consider number of cycles in \( V_{\leq l}(i) \) of any vertex \( i \in [n] \). We say \( H \) is \( l \)-tangle-free if for any \( i \in [n] \), there is no more than one cycle in \( V_{\leq l}(i) \).

**Lemma 4.4.** Assume \( l = c \log n \) with \( c \log(\alpha) < 1/4 \). Let \( (H, \sigma) \) be a sample from \( \mathcal{H}(n, d, p_n, q_n) \). Then
\[
\lim_{n \to \infty} \mathbb{P}_{\mathcal{H}_n} \left( \left| \{ i \in [n] : V_{\leq l}(i) \text{ contains at least one cycle} \} \right| \leq \log^2(n) \alpha^{2l} \right) = 1,
\]
\[
\lim_{n \to \infty} \mathbb{P}_{\mathcal{H}_n} (H \text{ is } l\text{-tangle-free}) = 1.
\]

The proof of Lemma 4.4 is given in Appendix A.2. In the next lemma, we translate the local analysis of the neighborhoods to the control of vectors \( B^{(m)} \mathbf{1}, B^{(m)} \sigma \). The proof is similar to the proof of Lemma 4.3 in [32], and we include it in Appendix A.3. For any event \( A_n \), we say \( A_n \) happens asymptotically almost surely if \( \lim_{n \to \infty} \mathbb{P}_{\mathcal{H}_n}(A_n) = 1 \).

**Lemma 4.5.** Let \( B \) be the set of vertices \( i \) whose \( l \)-neighborhood contains a cycle. For \( l = c \log n \) with \( c \log(\alpha) < 1/4 \), asymptotically almost surely the following holds:

1. For all \( m \leq l \) and all \( i \notin B \) the following holds
\[
(4.5) \quad (B^{(m-1)} \mathbf{1})_i = \alpha^{m-1-l} (B^{(l)} \mathbf{1})_i + O(\alpha^{(m-1)/2} \log n),
\]
\[
(4.6) \quad (B^{(m-1)} \sigma)_i = \beta^{m-1-l} (B^{(l)} \sigma)_i + O(\alpha^{(m-1)/2} \log n).
\]

2. For all \( i \in B \):
\[
(4.7) \quad |(B^{(m)} \sigma)_i| \leq |(B^{(m)} \mathbf{1})_i| \leq 2 \sum_{t=0}^m S_t(i) = O(\alpha^m \log n).
\]

Combining Theorem 3.1, Theorem 4.2, and Lemma 4.5, we are able to prove the following theorem.

**Theorem 4.6.** Assume \( \beta^2 > \alpha > 1 \) and \( l = c \log n \) with \( c \log(\alpha) < 1/8 \). Then the following holds: for any \( \varepsilon > 0 \)
\[
\lim_{n \to \infty} \mathbb{P}_{\mathcal{H}_n} \left( \sup_{\|x\|_2=1, x^\top (B^{(l)} \mathbf{1}) = x^\top (B^{(l)} \sigma) = 0} \|B^{(l)}x\|_2 \leq n^{\varepsilon} \alpha^{l/2} \right) = 1.
\]
Theorem 4.6 is a key ingredient to prove the bulk eigenvalues of $B^{(l)}$ are $O(n^{\alpha_l/2})$ in Theorem 6.1. The proof of Theorem 4.6 is given in in Section 9.

5. Coupling with multi-type Poisson hypertrees

Recall the definition of a hypertree from Definition 2.5. We construct a hypertree growth process in the following way. The hypertree is designed to obtain a coupling with the local neighborhoods of the random hypergraph $H$.

- Generate a root $\rho$ with spin $\tau(\rho) = +$, then generate $\text{Pois} \left( \frac{\alpha}{a - 1} \right)$ many hyperedges that only intersect at $\rho$. Call the vertices in these hyperedges except $\rho$ to be the children of $\rho$ and of generation 1. Call $\rho$ to be their parent.
- For $0 \leq r \leq d - 1$, we define a hyperedge is of type $r$ if $r$ many children in the hyperedge has spin $\tau(\rho)$ and $(d - 1 - r)$ many children has spin $-\tau(\rho)$. We first assign a type for each hyperedge independently. Each hyperedge will be of type $(d - 1)$ with probability $\frac{(d-1)^a}{\alpha^2 a!}$ and of type $r$ with probability $\frac{(d-1)^a r^{-1}}{\alpha^2 a!}$ for $0 \leq r \leq d - 2$. Since $\sum_{r=0}^{d-2} \frac{(d-1)^a r^{-1}}{\alpha^2 a!} = 1$, the probabilities of being various types of hyperedges add up to 1. Because the type is chosen i.i.d for each hyperedge, by Poisson thinning, the number of hyperedges of different types are independent and Poisson.
- We draw the hypertree in a plane and label each child from left to right. For each type $r$ hyperedge, we uniformly randomly pick $r$ vertices among $d - 1$ vertices in the first generation to put spins $\tau(\rho)$, and the rest $d - 1 - r$ many vertices are assigned with spins $-\tau(\rho)$.
- After defining the first generation, we keep constructing subsequent generations by induction. For each children $v$ with spin $\tau(v)$ in the previous generation, we generate $\text{Pois} \left( \frac{\alpha}{a - 1} \right)$ many hyperedges that pairwise intersects at $v$ and assign a type to each hyperedge by the same rule with $\tau(\rho)$ replaced by $\tau(v)$. We call such random hypergraphs with spins a multi-type Galton-Watson hypertree, denoted by $(T, \rho, \tau)$ (see Figure 3).

Let $W_t^\pm$ be the number of vertices with $\pm$ spins at the $t$-th generation and $W_t^{(r)}$ be the number of hyperedges which contains exactly $r$ children with spin $\pm$ in the $t$-th generation. Let $\mathcal{G}_{t-1} := \sigma(W_k^\pm, 1 \leq k \leq t - 1)$ be the $\sigma$-algebra generated by $W_k^\pm, 1 \leq k \leq t - 1$. From our definition, $W_0^+ = 1, W_0^- = 0$ and $(W_t^{(r)})_{0 \leq r \leq d-1}$ are independent conditioned on $\mathcal{G}_{t-1}$, and the conditioned laws of $W_t^{(r)}$ are given by

\begin{align}
\mathcal{L}(W_t^{(d-1)}|\mathcal{G}_{t-1}) &= \text{Pois} \left( \frac{a}{2d-1} W_{t-1}^+ + \frac{b}{2d-1} W_{t-1}^- \right), \\
\mathcal{L}(W_t^{(0)}|\mathcal{G}_{t-1}) &= \text{Pois} \left( \frac{a}{2d-1} W_{t-1}^- + \frac{b}{2d-1} W_{t-1}^+ \right), \\
\mathcal{L}(W_t^{(r)}|\mathcal{G}_{t-1}) &= \text{Pois} \left( \frac{b^{(d-1)r}}{2d-1} (W_{t-1}^- + W_{t-1}^+) \right), \quad 1 \leq r \leq d - 2.
\end{align}
We also have

\[(5.4)\]
\[
W_t^+ = \sum_{r=0}^{d-1} rW_t^{(r)}, \quad W_t^- = \sum_{r=0}^{d-1} (d - 1 - r)W_t^{(r)}.
\]

**Definition 5.1.** A rooted hypergraph is a hypergraph \(H\) with a distinguished vertex \(i \in V(H)\), denoted by \((H, i)\). We say two rooted hypergraphs \((H, i)\) and \((H', i')\) are isomorphic and if and only if there is a bijection \(\phi : V(H) \to V(H')\) such that \(\phi(i) = i'\) and \(e \in E(H)\) if and only if \(\phi(e) := \{\phi(j) : j \in e\} \in E(H')\).

Let \((H, i, \sigma)\) be a rooted hypergraph with root \(i\) and each vertex \(j\) is given a spin \(\sigma(j) \in \{-1, +1\}\). Let \((H', i', \sigma')\) be a rooted hypergraph with root \(i'\) where for each vertex \(j \in V(H')\), a spin \(\sigma'(j) \in \{-1, +1\}\) is given. We say \((H, i, \sigma)\) and \((H', i', \sigma')\) are spin-preserving isomorphic and denoted by \((H, i, \sigma) \equiv (H', i', \sigma')\) if and only if there is an isomorphism \(\phi : (H, i) \to (H', i')\) with \(\sigma(v) = \sigma'(\phi(v))\) for each \(v \in V(H)\).

Let \((H, i, \sigma), (T, \rho, \tau)\) be the rooted hypergraphs \((H, i, \sigma), (T, \rho, \tau)\) truncated at distance \(t\) from \(i, \rho\) respectively, and let \((T, \rho, -\tau)\) be the corresponding hypertree growth process where the root \(\rho\) has spin \(-1\). We prove a local weak convergence of a typical neighborhood of a vertex in the hypergraph \(H\) to the hypertree process \(T\) we described above. In fact, we prove the following stronger statement. The proof of Theorem 5.2 is given in Section 5.

**Theorem 5.2.** Let \((H, \sigma)\) be a random hypergraph \(H\) with spin \(\sigma\) sampled from \(\mathcal{H}_n\). Let \(i \in [n]\) be fixed with spin \(\sigma_i\). Let \(l = c \log(n)\) with \(c \log(n) < 1/4\), the following holds for sufficiently large \(n\).

1. If \(\sigma_i = +1\), there exists a coupling between \((H, i, \sigma)\) and \((T, \rho, \tau)\) such that \((H, i, \sigma)_l \equiv (T, \rho, \tau)_l\) with probability at least \(1 - n^{-1/5}\).
2. If \(\sigma_i = -1\), there exists a coupling between \((H, i, \sigma)\) and \((T, \rho, -\tau)\) such that \((H, i, \sigma)_l \equiv (T, \rho, -\tau)_l\) with probability at least \(1 - n^{-1/5}\).

Now we construct two martingales from the Poisson hypertree growth process. Define two processes

\[
M_t := \alpha^{-t}(W_t^+ + W_t^-), \quad \Delta_t := \beta^{-t}(W_t^+ - W_t^-).
\]

**Lemma 5.3.** The two processes \(\{M_t\}, \{\Delta_t\}\) are \(\mathbb{G}_t\)-martingales. If \(\beta^2 > \alpha > 1\), \(\{M_t\}\) and \(\{\Delta_t\}\) are uniformly integrable. The martingale \(\{\Delta_t\}\) converges almost surely and in \(L^2\) to a unit mean random variable \(\Delta_\infty\). Moreover, \(\Delta_\infty\) has a finite variance and

\[(5.5)\]
\[
\lim_{t \to \infty} \mathbb{E}|\Delta_t^2 - \Delta_\infty^2| = 0.
\]

The following Lemma will be used in the proof of Theorem 1.1 to analyze the correlation between the estimator we construct and the correct labels of vertices based on the random variable \(\Delta_\infty\). The proof is similar to the proof of Theorem 4.2 in [32], and we include it in Appendix A.5.

**Lemma 5.4.** Let \(l = c \log n\) with \(c \log(n) < 1/8\). For any \(\varepsilon > 0\),

\[(5.6)\]
\[
\lim_{n \to \infty} \mathbb{P}_{\mathcal{H}_n} \left( \left| \frac{1}{n} \sum_{i=1}^{n} \beta^{-2l}D_l^2(i) - \mathbb{E}[\Delta_\infty^2] \right| > \varepsilon \right) = 0.
\]

Let \(y_n^{(n)} \in \mathbb{R}^n\) be a random sequence of \(l_2\)-normalized vectors defined by

\[
y_i^{(n)} := \frac{D_l(i)}{\sqrt{\sum_{j=1}^{n} D_l(j)^2}} 1 \leq i \leq n.
\]

Let \(x_n\) be any sequence of random vectors in \(\mathbb{R}^n\) such that for any \(\varepsilon > 0\),

\[
\lim_{n \to \infty} \mathbb{P}_{\mathcal{H}_n}(\|x_n - y_n^{(n)}\|_2 > \varepsilon) = 0.
\]
For all $\tau \in \mathbb{R}$ that is a point of continuity of the distribution of both $\Delta_\infty$ and $-\Delta_\infty$, for any $\varepsilon > 0$, one has the following

\begin{equation}
\lim_{n \to \infty} \mathbb{P}_{\mathcal{H}_n} \left( \frac{1}{n} \sum_{i \in [n], \sigma_i = +} 1 \{ x_i^{(n)} \geq \tau / \sqrt{n \mathbb{E}[\Delta_\infty^2]} \} - \frac{1}{2} \mathbb{P}(\Delta_\infty \geq \tau) > \varepsilon \right) = 0,
\end{equation}

\begin{equation}
\lim_{n \to \infty} \mathbb{P}_{\mathcal{H}_n} \left( \frac{1}{n} \sum_{i \in [n], \sigma_i = -} 1 \{ x_i^{(n)} \geq \tau / \sqrt{n \mathbb{E}[\Delta_\infty^2]} \} - \frac{1}{2} \mathbb{P}(-\Delta_\infty \geq \tau) > \varepsilon \right) = 0.
\end{equation}

6. PROOF OF THE MAIN RESULT

Let $\bar{S}_l := (S_l(1), \ldots, S_l(n))$ and $\bar{D}_l := (D_l(1), \ldots, D_l(n))$. We say the sequence of vectors $\{v_n\}_{n \geq 1}$ is asymptotically aligned with the sequence of vectors $\{w_n\}_{n \geq 1}$ if

\[ \lim_{n \to \infty} \frac{\langle v_n, w_n \rangle}{\|v_n\|_2 \cdot \|w_n\|_2} = 1. \]

With all the ingredients in Sections 3-5, we establish the following weak Ramanujan property of $B^{(l)}$. The proof of Theorem 6.1 is given in Section 11.

**Theorem 6.1.** For $l = c \log(n)$ with $c \log(\alpha) < 1/8$, asymptotically almost surely the two leading eigenvectors of $B^{(l)}$ are asymptotically aligned with vectors $\bar{S}_l, \bar{D}_l$, where the first eigenvalue is of order $\Theta(\alpha^l)$ up to some logarithmic factor and the second eigenvalue is of order $\Omega(\beta^l)$. All other eigenvalues are of order $O(n^{\sigma} \alpha^{l/2})$ for any $\varepsilon > 0$.

Theorem 6.1 connects the leading eigenvectors of $B^{(l)}$ with the local structures of the random hypergraph $H$ and shows that the bulk eigenvalues of $B^{(l)}$ are separated from the two top eigenvalues. Equipped with Theorem 6.1 and Lemma 5.4, we are ready to prove our main result.

**Proof of Theorem 1.1.** Let $x^{(n)}$ be the $l_2$-normalized second eigenvector of $B^{(l)}$, by Theorem 6.1, $x^{(n)}$ is asymptotically aligned with the $l_2$-normalized vector

\[ y_i^{(n)} = \frac{D_l(i)}{\sqrt{\sum_{j=1}^{n} D_l(j)^2}} \]

asymptotically almost surely. So we have $\|x^{(n)} - y^{(n)}\|_2 \to 0$ or $\|x^{(n)} + y^{(n)}\|_2 \to 0$ asymptotically almost surely. We first assume $\|x^{(n)} - y^{(n)}\|_2 \to 0$. Since $\mathbb{E}[\Delta_\infty] = 1$, from the proof of Theorem 2.1 in [32], there exists a point $\tau \in \mathbb{R}$, in the set of continuity points of both $\Delta_\infty$ and $-\Delta_\infty$, that satisfies $r := \mathbb{P}(\Delta_\infty \geq \tau) - \mathbb{P}(-\Delta_\infty \geq \tau) > 0$. Take $t = \tau / \sqrt{\mathbb{E}[\Delta_\infty^2]}$ and let $N^+, N^-$ be the set of vertices with spin + and -, respectively. From the definition of $\hat{\sigma}$, we have

\begin{equation}
\frac{1}{n} \sum_{i \in [n]} \sigma_i \hat{\sigma}_i = \frac{1}{n} \sum_{i \in [n]} \sigma_i \left( 1 \{ x_i^{(n)} \geq t / \sqrt{n} \} - 1 \{ x_i^{(n)} < t / \sqrt{n} \} \right)
\end{equation}

\begin{equation}
= \frac{1}{n} \sum_{i \in [n]} \sigma_i + \frac{2}{n} \sum_{i \in N^+} 1 \{ x_i^{(n)} \geq \tau / \sqrt{n \mathbb{E}[\Delta_\infty]} \} - \frac{2}{n} \sum_{i \in N^-} 1 \{ x_i^{(n)} \geq \tau / \sqrt{n \mathbb{E}[\Delta_\infty]} \}.
\end{equation}

Note that $\frac{1}{n} \sum_{i \in [n]} \sigma_i \to 0$ in probability by the law of large numbers. From (5.7) in Lemma 5.4, we have (6.1) converges in probability to $\mathbb{P}(\Delta_\infty \geq \tau) - \mathbb{P}(-\Delta_\infty \geq \tau) = r$. If $\|x^{(n)} + y^{(n)}\|_2 \to 0$, similarly we have $\frac{1}{n} \sum_{i \in [n]} \sigma_i \hat{\sigma}_i$ converges to $-r$ in probability. From these two cases, for any $\varepsilon > 0$,

\[ \lim_{n \to \infty} \mathbb{P}_{\mathcal{H}_n} \left( \{ |ov_n(\hat{\sigma}, \sigma) - r| > \varepsilon \} \cap \{ |ov_n(\hat{\sigma}, \sigma) + r| > \varepsilon \} \right) = 0. \]

This concludes the proof of Theorem 1.1. \qed
7. Proof of Theorem 3.1

7.1. Proof of (3.2) in Theorem 3.1. For ease of notation, we drop the index \( n \) in the proof, and it will be clear from the law \( H_n \). For any sequences of real numbers \( \{a_t\}_{t=1}^l, \{b_t\}_{t=1}^l \), we have the following expansion identity for \( l \geq 2 \) (see for example, Equation (15) in [32] and Equation (27) in [8]):

\[
\prod_{t=1}^l (a_t - b_t) = \prod_{t=1}^l a_t - \sum_{m=1}^{l-1} \left( \prod_{t=1}^{l-m} (a_t - b_t) \right) b_{l-m+1} \prod_{t=l-m+2}^l a_t.
\]

Therefore the following identity holds.

\[
\prod_{t=1}^l (A_{it-1}^{e_{it}} - A_{it-1}^e) = \prod_{t=1}^l A_{it-1}^{e_{it}} - \sum_{m=1}^{l-1} \left( \prod_{t=1}^{l-m} (A_{it-1}^{e_{it}} - A_{it-1}^e) \right) A_{it-1}^{e_{i-m+1}} \prod_{t=l-m+2}^l A_{it-1}^{e_{it}}.
\]

Summing over all \( w \in \text{SAW}_{ij} \), \( \Delta_{ij}^{(l)} \) can be written as

\[
B_{ij}^{(l)} - \sum_{m=1}^{l} \sum_{w \in \text{SAW}_{ij}} \left( \prod_{t=1}^{l-m} (A_{it-1}^{e_{it}} - A_{it-1}^e) \right) A_{it-1}^{e_{i-m+1}} \prod_{t=l-m+2}^l A_{it-1}^{e_{it}}.
\]

Introduce the set \( Q_{ij}^m \) of walks \( w \) defined by concatenations of two self-avoiding walks \( w_1, w_2 \) such that \( w_1 \) is a self-avoiding walk of length \( l - m \) from \( i \) to some vertex \( k \), and \( w_2 \) is a self-avoiding walk of length \( m \) from \( k \) to \( j \) for all possible \( 1 \leq m \leq l \) and \( k \in [n] \). Then \( \text{SAW}_{ij} \subset Q_{ij}^m \) for all \( 1 \leq m \leq l \). Let \( R_{ij}^m = Q_{ij}^m \setminus \text{SAW}_{ij} \).

Define the matrix \( \Gamma^{(l,m)} \) as

\[
\Gamma_{ij}^{(l,m)} := \sum_{w \in R_{ij}^m} \left( \prod_{t=1}^{l-m} (A_{it-1}^{e_{it}} - A_{it-1}^e) \right) A_{it-1}^{e_{i-m+1}} \prod_{t=l-m+2}^l A_{it-1}^{e_{it}}.
\]

From (7.1), \( \Delta_{ij}^{(l)} \) can be expanded as

\[
B_{ij}^{(l)} - \sum_{m=1}^{l} \sum_{w \in Q_{ij}^m \setminus R_{ij}^m} \left( \prod_{t=1}^{l-m} (A_{it-1}^{e_{it}} - A_{it-1}^e) \right) A_{it-1}^{e_{i-m+1}} \prod_{t=l-m+2}^l A_{it-1}^{e_{it}} + \sum_{m=1}^{l} \Gamma_{ij}^{(l,m)}.
\]

It can be further written as

\[
B_{ij}^{(l)} - \sum_{m=1}^{l} \sum_{w \in Q_{ij}^m} \left( \prod_{t=1}^{l-m} (A_{it-1}^{e_{it}} - A_{it-1}^e) \right) A_{it-1}^{e_{i-m+1}} \prod_{t=l-m+2}^l A_{it-1}^{e_{it}} + \sum_{m=1}^{l} \Gamma_{ij}^{(l,m)}.
\]

From the definition of matrix multiplication, we have

\[
\sum_{w \in Q_{ij}^m} \prod_{t=1}^{l-m} (A_{it-1}^{e_{it}} - A_{it-1}^e) A_{it-1}^{e_{i-m+1}} \prod_{t=l-m+2}^l A_{it-1}^{e_{it}} = \sum_{1 \leq u, v \leq n} \Delta_{iu}^{(l-m)} \overline{A}_{uv} B_{vj}^{(m-1)} = \Delta_{ij}^{(l-m)} \overline{A} B^{(m-1)}
\]

Combining the expansion of \( \Delta_{ij}^{(l)} \) above and (7.3), we obtain

\[
\Delta_{ij}^{(l)} = B_{ij}^{(l)} - \sum_{m=1}^{l} (\Delta_{ij}^{(l-m)} \overline{A} B^{(m-1)}) + \sum_{m=1}^{l} \Gamma_{ij}^{(l,m)}.
\]

Since (7.4) is true for any \( i, j \in [n] \), it implies (3.2).
7.2. Proof of (3.3) in Theorem 3.1. We first prove the following spectral norm bound on $\Delta(1)$.

Lemma 7.1. For $l = O(\log n)$ and fixed $k$, we have

$$E_{H_n}[\rho(\Delta(1))^{2k}] = O(na^{kl}\log^6 n). \quad (7.5)$$

Proof. Note that $E_{H_n}[\rho(\Delta(1))^{2k}] \leq E_{H_n}[\text{tr}(\Delta(1))^{2k}]$. The estimation is based on a coding argument, and we modify the proof in [32] to count circuits in hypergraphs. Let $W_{2k,l}$ be the set of all circuits of length $2kl$ in the complete hypergraph $K_{n,d}$ which are concatenations of $2k$ many self-avoiding walks of length $l$. For any circuits $w \in W_{2k,l}$, we denote it by $w = (i_0, e_{i_1}, i_1, \ldots, e_{i_{2kl}}, i_{2kl})$, with $i_{2kl} = i_0$. From (3.1), we have

$$E_{H_n}[\text{tr}(\Delta(1))^{2k}] = \sum_{j_1, \ldots, j_{2k} \in [n]} E_{H_n}[\Delta_{j_1j_2}(1) \Delta_{j_2j_3}(1) \cdots \Delta_{j_{2k}j_1}(1)] = \sum_{w \in W_{2k,l}} E_{H_n}\left[\prod_{i=1}^{2kl} (A_{i_{i-1}i_i} - A_{i_{i-1}i_i})\right]. \quad (7.6)$$

For each circuit, the weight it contributes to the sum is the product of $(A_{ij} - A_{ij})$ over all the hyperedges $e$ traversed in the circuits. In order to have an upper bound on $E_{H_n}[\text{tr}(\Delta(1))^{2k}]$, we need to estimate how many such circuits are included in the sum and what are the weights they contribute.

We also write $w = (w_1, w_2, \ldots, w_{2k})$, where each $w_i$ is a self-avoiding walk of length $l$. Let $v$ and $h$ be the number of distinct vertices and hyperedges traversed by the circuit respectively. The idea is to bound the number of all possible circuits $w$ in (7.6) with given $v$ and $h$, and then sum over all possible $(v, h)$ pairs.

Fix $v$ and $h$, and for any circuit $w$ we form a labeled multigraph $G(w)$ with labeled vertices $\{1, \ldots, v\}$ and labeled multiple edges \{e_{1}, \ldots, e_{h}\} by the following rules:

- Label the vertices in $G(w)$ by the order they first appear in $w$, starting from 1. For any pair vertices $i, j \in [v]$, we add an edge between $i, j$ in $G(w)$ whenever a hyperedge appears between the $i$-th and $j$-th distinct vertices in the circuit $w$. $G(w)$ is a multigraph since it’s possible that for some $i, j$, there exists two distinct hyperedges connecting the $i$-th and $j$-th distinct vertices in $w$, which corresponds to two distinct edges in $G(w)$ connecting $i, j$.

- Label the edges in $G(w)$ by the order in which the corresponding hyperedge first appears in $w$ from $e_1$ to $e_h$. Note that that the number of edges in $G(w)$ is at least $h$, since distinct edges in $G(w)$ can get the same hyperedge labels. At the end we obtain a multigraph $G(w) = (V(w), E(w))$ with vertex set $\{1, \ldots, v\}$ and edge set $E(w)$ with hyperedge labels in $\{e_{1}, \ldots, e_{h}\}$.

It’s crucial to see that the labeling of vertices and edges in $G(w)$ is in order, and it tells us how the circuit $w$ is traversed. Consider any edge in $G(w)$ such that its right endpoint (in the order of the traversal of $w$) is a new vertex that has not been traversed by $w$. We call it a tree edge. Denote by $T(w)$ the tree spanned by those edges. It’s clear for the construction that $T(w)$ includes all vertices in $G(w)$, so $T(w)$ is a spanning tree of $G(w)$. Since the labels of vertices and edges are given in $G(w)$, $T(w)$ is uniquely defined. See Figure 4 for an example.

For a given $w \in W_{2k,l}$ with distinct hyperedges $e_{1}, \ldots, e_{h}$, define end($e_i$) to be the set of vertices in $V(w)$ such that they are the endpoints of edges with label $e_i$ in $G(w)$. For example, consider a hyperedge $e_1 = \{1, 2, 3, 4\}$ such that $\{1, 2\}, \{1, 3\}$ are all the edges in $G(w)$ with labels $e_1$, then end($e_1$) = $\{1, 2, 3\}$. We consider circuits $w$ in three different cases and estimate their contribution to (7.6) separately.

Case (1). We first consider $w \in W_{2k,l}$ such that

- each hyperedge label in $\{e_i\}_{1 \leq i \leq h}$ appears exactly once on the edges of $G(w)$;
- vertices in $e_i \setminus \text{end}(e_i)$ are all distinct for $1 \leq i \leq h$, and they are not vertices with labels in $V(w)$.

The first condition implies the number of edges in $G(w)$ is $h$. The second condition implies that there are exactly $(d - 2)h + v$ many distinct vertices in $w$. We will break each self-avoiding walk $w_i$ into three types of successive sub-walks where each sub-walk is exactly one of the following 3 types, and we encode these sub-walks as follows.

- Type 1: hyperedges with corresponding edges in $G(w) \setminus T(w)$. Given our position in the circuit $w$, we can encode a hyperedge of this type by its right-end vertex. Hyperedges of Type 1 breaks the walk $w_i$ into disjoint sub-walks, and we partition these sub-walks into Type 2 and 3 below.
- Type 2: sub-walks such that all their hyperedges correspond to edges of $T(w)$ and have been traversed already by $w_1, \ldots, w_{i-1}$. Each sub-walk is a part of a self-avoiding walk, and it is a path contained
Figure 4. A multigraph $G(w)$ associated to a circuit $w = (w_1, \ldots, w_d)$ of length $2kl$ with $k = 2, l = 5$. $w_1 = (1, e_1, 2, e_2, 3, e_3, 4, e_4, 5, e_5, 6)$, $w_2 = (6, e_5, 5, e_4, 6, e_6, 7, e_7, 8, e_8, 3)$, $w_3 = (3, e_2, 2, e_1, 1, e_9, 9, e_{10}, 10, e_{11}, 11)$, $w_4 = (11, e_{12}, 10, e_{10}, 9, e_{13}, 12, e_{14}, 13, e_{15}, 1)$. Edges that are not included in $T(w)$ are $\{e_8, e_{12}, e_{15}\}$. The triplet sequences associated to the 4 self-avoiding walks $\{w_i\}_{i=1}^4$ are given by $(0, 6, 0)$, $(4, 2, 3), (0, 0, 0), (1, 3, 0)$, and $(0, 0, 10), (9, 2, 1), (0, 0, 0)$, respectively.

in the tree $T(w)$. Given its initial and its end vertices, there will be exactly one such path in $T(w)$. Therefore these walks can be encoded by the end vertices.

- **Type 3**: sub-walks such that their hyperedges correspond to edges of $T(w)$ and they are being traversed for the first time. Given the initial vertex of a sub-walk of this type, since it is traversing new edges and knowing in what order the vertices are discovered, we can encode these walks by its length, and from the given length, we know at which vertex the sub-walk ends.

We encode any Type 1, Type 2, or Type 3 sub-walk by 0 if the sub-walk is empty. Now we can decompose each $w_i$ into sequences characterizing by its sub-walks:

$$\{p_1, q_1, r_1\}, \{p_2, q_2, r_2\}, \ldots, \{p_t, q_t, r_t\}. \tag{7.7}$$

Here $r_1, \ldots, r_{t-1}$ are codes from sub-walks of Type 1. From the way we encode such hyperedges, we have $r_i \in \{1, \ldots, v\}$ for $1 \leq i \leq t - 1$. Type 2 and Type 3 sub-walks are encoded by $p_1, \ldots, p_t$ and $q_1, \ldots, q_t$ respectively. Since Type 1 hyperedges break $w$ into disjoint pieces, we use $(p_i, q_i, r_i)$ to represent the last piece of the sub-walk and make $r_i = 0$. Each $p_i$ represents the right-end vertex of the Type 2 sub-walk, and $p_i = 0$ if it the sub-walk is empty, hence $p_i \in \{0, \ldots, v\}$ for $1 \leq i \leq t$. Each $q_i$ represents the length of Type 3 sub-walks, so $q_i \in \{0, \ldots, l\}$ for $1 \leq i \leq t$. From the way we encode these sub-walks, there are at most $(v + 1)^2(l + 1)$ many possibilities for each triplet $(p_i, q_i, r_i)$.

We now consider how many ways we can concatenate sub-walks encoded by the triplets to form a circuit $w$. All triples with $r_j \in [v]$ for $1 \leq j \leq t - 1$ indicate the traversal of an edge not in $T(w)$. Since we know the number of edges in $G(w) \setminus T(w)$ is $(h - v + 1)$, and within a self-avoiding walk $w_{t+1}$, edges on $G(w)$ can be traversed at most once, the length of the triples in (7.7) satisfies $t - 1 \leq h - v + 1$, which implies $t \leq h - v + 2$.

Since each hyperedge can be traversed at most $2k$ many times by $w$ due to the constraint that the circuits $w$ of length $2kl$ are formed by self-avoiding walks, so the number of triple sequences for fixed $v, h$ is at most $[(v + 1)^2(l + 1)]^{2k(2+h-v)}$.

There are multiple $w$ with the same code sequence. However, they must all have the same number of vertices and edges, and the positions where vertices and hyperedges are repeated must be the same. The number of ordered sequences of $v$ distinct vertices is at most $n^v$. Given the vertex sequence, the number of ordered sequences of $h$ distinct hyperedges in $K_{n,h}$ is at most $\binom{n}{d-2}^h$. This is because for a hyperedge $e$ between two vertices $i, j$, the number of possible hyperedges containing $i, j$ is at most $\binom{n}{d-2}$. Therefore, given $v, h$, the number of circuits that share the same triple sequence (7.7) is at most $n^v\binom{n}{d-2}^h$. Combining all the two estimates, the number of all possible circuits $w$ with fixed $v, h$ in Case (1) is at most

$$n^v\binom{n}{d-2}^h [(v + 1)^2(l + 1)]^{2k(2+h-v)}.$$
Now we consider the expected weight of each circuit in the sum (7.6). Given $\sigma$, if $i, j \in e$, we have $A_{ij}^e \sim \text{Ber}(p_{\sigma(e)})$, where $p_{\sigma(e)} = \frac{a}{d-1}$ if vertices in $e$ have the same $\pm$ spins and $p_{\sigma(e)} = \frac{b}{d-1}$ otherwise. For a given hyperedge appearing in $w$ with multiplicity $m \in \{1, \ldots, 2k\}$, the corresponding expectation $E_{H_n} [(A_{ij}^e - \overline{A}_{ij}^e)^m] = 0$ if $m = 1$. Since $0 \leq A_{ij} \leq 1$, for $m \geq 2$, we have

$$
E_{H_n} [(A_{ij}^e - \overline{A}_{ij}^e)^m | \sigma] \leq E_{H_n} [(A_{ij}^e - \overline{A}_{ij}^e)^2 | \sigma] \leq p_{\sigma(e)}.
$$

For any hyperedge $e$ corresponding to an edge in $G(w) \setminus T(w)$ we have the upper bound

$$
p_{\sigma(e)} \leq \frac{a \vee b}{(d-1)n}.
$$

Taking the expectation over $\sigma$ we have

$$
E_\sigma[p_{\sigma(e)}] = a + \frac{(2d-1)b}{2d-1} \binom{n}{d-1} = \frac{\alpha}{(d-1)n}.
$$

Recall the weight of each circuit in the sum (7.6) is given by

$$
E_{H_n} \left[ \prod_{i=1}^{2kl} (A_{i1-1i1}^e - \overline{A}_{i1-1i1}^e) \right].
$$

Conditioned on $\sigma$, $(A_{i1-1i1}^e - \overline{A}_{i1-1i1}^e)$ are independent random variables for distinct hyperedges. Denote these distinct hyperedges by $e_1, \ldots, e_h$ with multiplicity $m_1, \ldots, m_h$ and we temporarily order them such that $e_1, \ldots, e_{v-1}$ are the hyperedges corresponding to edges on $T(w)$. Introduce the random variables $A^{e_i} \sim \text{Ber}(p_{\sigma(e_i)})$ for $1 \leq i \leq h$ and denote $\overline{A}^{e_i} = E_{H_n}[A^{e_i} | \sigma]$. Therefore from (7.9) we have

$$
E_{H_n} \left[ \prod_{i=1}^{2kl} (A_{i1-1i1}^{e_i} - \overline{A}_{i1-1i1}^{e_i}) \right] = E_\sigma \left[ \prod_{i=1}^{2kl} (A_{i1-1i1}^{e_i} - \overline{A}_{i1-1i1}^{e_i}) \right] = E_\sigma \left[ \prod_{i=1}^{h} \prod_{j=1}^{m_i} (A^{e_i} - \overline{A}^{e_i})^m_i | \sigma \right] \leq E_\sigma \left[ \prod_{i=1}^{h} p_{\sigma(e_i)} \right].
$$

We use the bound (7.10) for $p_{\sigma(e_1)}, \ldots, p_{\sigma(e_h)}$, which implies

$$
E_\sigma \left[ \prod_{i=1}^{h} p_{\sigma(e_i)} \right] \leq \left( \frac{a \vee b}{(d-1)} \right)^{h+1} E_\sigma \left[ \prod_{i=1}^{v-1} p_{\sigma(e_i)} \right].
$$

From the second condition for $w$ in Case (1), any two hyperedges among $\{e_1, \ldots, e_{v-1}\}$ share at most 1 vertex, $p_{\sigma(e_i)}, p_{\sigma(e_j)}$ are pairwise independent for all $1 \leq i < j \leq v-1$. Moreover, since the corresponding edges of $e_1, \ldots, e_{v-1}$ forms the spanning tree $T(w)$, taking any $e_j$ such that the corresponding edge in $T(w)$ is attached to some leaf, we know $e_j$ and $\bigcup_{i \neq j, 1 \leq i \leq v} e_i$ share exactly one common vertex, therefore $p_{\sigma(e_j)}$ is independent of $\prod_{i \neq j, 1 \leq i \leq v} p_{\sigma(e_i)}$. We then have

$$
E_\sigma \left[ \prod_{i=1}^{v-1} p_{\sigma(e_i)} \right] = E_\sigma[p_{\sigma(e_j)}] \cdot E_\sigma \left[ \prod_{1 \leq i \leq v-1, i \neq j} p_{\sigma(e_i)} \right].
$$

Now the corresponding edges of all hyperedges $\{e_1, \ldots, e_{v-1}\} \setminus \{e_j\}$ form a tree in $G(w)$ again and the factorization of expectation in (7.13) can proceed as long as we have some edge attached to leaves. Repeating (7.13) recursively, with (7.11), we have

$$
E_\sigma \left[ \prod_{i=1}^{v-1} p_{\sigma(e_i)} \right] = \prod_{i=1}^{v-1} E_\sigma[p_{\sigma(e_i)}] = \left( \frac{\alpha}{(d-1)n} \right)^{v-1}.
$$

Since every hyperedge in $w$ must be visited at least twice to make its expected weight non-zero, and $w$ is of length $2kl$, we must have $h \leq kl$. In the multigraph $G(w)$, we have the constraint $v \leq h + 1 \leq kl + 1$. Since the first self-avoiding walk in $w$ of length $l$ takes $l + 1$ distinct vertices, we also have $v \geq l + 1$. So the possible range of $v$ is $l + 1 \leq v \leq kl + 1$ and $h$ satisfies $v - 1 \leq h \leq kl$.
Putting all the estimates in (7.8), (7.12), and (7.14) together, for fixed \( v, h \), the total contribution of self-avoiding walks from \( W_{2k,l}^t \) to the sum is bounded by

\[
n^v \left( \frac{n}{d-2} \right)^h [(v + 1)^2(l + 1)]^{2k(2 + h - v)} \frac{\alpha}{(d - 1)\left(\frac{n}{d-1}\right)} v^{-1} \left( \frac{a \lor b}{(n/d-1)} \right)^{h-v+1}.
\]

Denote \( S_1 \) to be the sum of all contributions from walks in Case (1). Therefore

\[
(7.15) \quad S_1 \leq \sum_{v=l+1}^{k+l+1} \sum_{h=v-1}^{kl} n^v \left( \frac{d-1}{n-d+2} \right)^h \left( \frac{\alpha}{d-1} \right)^{v-1} [(v + 1)^2(l + 1)]^{2k(2 + h - v)} (a \lor b)^{h-v+1}.
\]

When \( l = O(\log n) \), since \( d, k \) are fixed, for sufficiently large \( n \), \( \left( \frac{n}{n-d+2} \right)^h \leq 2 \). Then from (7.15),

\[
S_1 \leq \sum_{v=l+1}^{k+l+1} \sum_{h=v-1}^{kl} 2n^{v-h}(d-1)^{-h-v+1} [(v + 1)^2(l + 1)]^{2k(2 + h - v)} \frac{(a \lor b)^{h-v+1}}{n}.
\]

Hence

\[
(7.16) \quad \frac{S_1}{n^{\alpha kl}[(kl+2)^2(l+1)]^{2k}} \leq 2 \sum_{v=l+1}^{k+l+1} \sum_{h=v-1}^{kl} \left[ n^{-1}(a \lor b)(d-1)((kl+2)^2(l+1))^{2k} \right]^{h-v+1}.
\]

Since for fixed \( d, k \) and \( l = O(\log n) \), \( n^{-1}(a \lor b)(d-1)((kl+2)^2(l+1))^{2k} = o(1) \) for \( n \) sufficiently large, the leading term in (7.16) is the term with \( h = v - 1 \). For sufficiently large \( n \), we have

\[
\frac{S_1}{n^{\alpha kl}[(kl+2)^2(l+1)]^{2k}} \leq 3 \sum_{v=l+1}^{k+l+1} \alpha^{v-1-kl} = 3 \cdot \frac{\alpha - \alpha(1-k)l}{\alpha - 1} \leq \frac{3\alpha}{\alpha - 1}.
\]

It implies that \( S_1 = O(n^{\alpha kl} \log \log n) \).

**Case (2).** We now consider \( w \in W_{2k,l} \) such that

- the number of edges in \( G(w) \) is greater than \( h \).
- vertices in \( e_i \cup \text{end}(e_i) \) are all distinct for \( 1 \leq i \leq h \), and they are not vertices with labels in \( V(w) \).

Let \( \tilde{h} \) be the number of edges in \( G(w) \) with \( \tilde{h} \geq h + 1 \). Same as in Case (1), the number of triple sequence is at most \( [(v + 1)^2(l + 1)]^{2k(2 + h - v)} \). Let \( s_i, 1 \leq i \leq h \) be the size of \( \text{end}(e_i) \). By our definition of \( s_i \), we have \( \sum_{i=1}^{h} (s_i - 2) \geq \tilde{h} - h \). We first pick edges with distinct hyperedge labels and label their vertices, then label the remaining vertices from edges with repeated hyperedge labels, each at most \( (d - 2) \) choices. The number of all possible circuits in Case (2) with fixed \( v, h, \tilde{h} \) is bounded by

\[
[(v + 1)^2(l + 1)]^{2k(2 + \tilde{h} - v)} n^{v-\tilde{h}-(h-\tilde{h})} (d-2)^{\tilde{h}-h} \left( \frac{n}{d-s_i} \right) \cdots \left( \frac{n}{d-s_h} \right).
\]

For large \( n \), the quantity above is bounded by

\[
2[(v + 1)^2(l + 1)]^{2k(2 + \tilde{h} - v)} n^{v-\tilde{h}+h} (d-2)^{\tilde{h}-h} \left( \frac{d-1}{n} \right)^{\tilde{h}} \left( \frac{n}{d-1} \right)^h.
\]

Now we consider the expected weight of each circuit in Case (2). In the spanning tree \( T(w) \), we keep edges with distinct hyperedge labels that appear first in the circuit \( w \) and remove other edges. This gives us a forest denoted \( F(w) \) inside \( T(w) \), with at least \( v - 1 - \tilde{h} + h \) many edges. We temporarily label those edges in the forest as \( e_1, \ldots, e_q \) with \( q = v - 1 - \tilde{h} + h \). Then similar to the analysis of (7.14) in Case (1),

\[
E_{\mathcal{H}_n} \left[ \prod_{i=1}^{2kl} (A_{i_{i-1}} \delta_j - A_{i_{i-1}} \delta_{j+1}) \right] \leq E_{\mathcal{H}} \left[ \prod_{i=1}^{\tilde{h}} (\frac{n}{d-1})^{\tilde{h}-v+1} \left( \frac{\alpha}{d-1} \right)^{v-1-\tilde{h}+h} \right].
\]
After removing the $t$ edges, we have at least $(v+1)^2(l+1)$ hyperedges. This implies (3.3) in the statement of Theorem 3.1. 

Let $v, h, \tilde{h}, s_i$ be defined in the same way as in Case (2). The number of triple sequence is at most $(v+1)^2(l+1)2^k(2h-v)$. Consider the forest $F(w)$ introduced in Case (2) as a subgraph of $T(w)$, which has at least $v - 1 - \tilde{h} + h$ many edges with distinct hyperedge labels. We temporarily denote the edges by $e_1, \ldots, e_p$, and the ordering is chosen such that $e_1$ is adjacent to a leaf in $F(w)$, and each $e_i, i \leq 2$ is adjacent to a leaf in $F(w) \setminus \{e_1, \ldots, e_i-1\}$. For $1 \leq i \leq q$, we call $e_i$ a bad hyperedge if $e_i \setminus \text{end}(e_i)$ share a vertex with some $e_j \setminus \text{end}(e_j)$ with $j > i$, or there are vertices in $e_i \setminus \text{end}(e_i)$ with labels in $V(w)$. Suppose among them there are $t$ bad hyperedges with $0 \leq t \leq v - 1$. Let $\delta_i = 1$ if $e_i$ is a bad hyperedge, and $\delta_i = 0$ otherwise. Then the number of all possible circuits in Case (3) with fixed $v, h, \tilde{h}$, and $t$, is bounded by

$$
[(v+1)^2(l+1)]2^k(2h-v)n^{v-h+h}(d-2)^{\tilde{h}-h}(d-s_1-\delta_1)\cdots(d-s_{\tilde{h}}-\delta_{\tilde{h}})\leq 2[(v+1)^2(l+1)]2^k(2h-v)n^{v-h+h}(d-2)^{\tilde{h}-h}(d-1))^{\frac{d-1}{n}}\left(\frac{n}{d-1}\right)^h.
$$

After removing the $t$ edges with bad hyperedge labels from the forest $F(w)$, we can do the same analysis as in Case (2). The expected weight of each circuit in Case (3) with given $v, h, \tilde{h}, t$ now satisfies

$$
\mathbb{E}_{H_n} \left[ \prod_{i=1}^{2k} (\mathcal{A}_{v-i} - \mathcal{A}_{u-i}) \right] \leq \left( \frac{a \lor b}{\binom{n}{d-1}} \right)^{h-v+1+t} \left( \frac{\alpha}{(d-1)\binom{n}{d-1}} \right)^{v-1-\tilde{h}+h-t}.
$$

Let $S_3$ be the total contribution from circuits in Case (3) to (7.6) . Then

$$
S_3 \leq \sum_{h=1}^{kl} \sum_{h=h+1}^{v-1} \sum_{t=0}^{v-1} 2[(v+1)^2(l+1)]2^k(2h-v)n^{v-h+h}(d-2)^{\tilde{h}-h}(d-1))^{\frac{d-1}{n}}\left(\frac{n}{d-1}\right)^h.
$$

From the estimates on $S_1, S_2$ and $S_3$, Lemma 7.1 holds. 

With Lemma 7.1, we are able to derive (3.3). For any fixed $\varepsilon > 0$, choose $k$ such that $1 - 2k\varepsilon < 0$, using Markov inequality, we have

$$
\mathbb{P}_{H_n}(\rho(\Delta) \geq n^2 \alpha l^{1/2}) \leq \frac{\mathbb{E}_{H_n}(\rho(\Delta)^{2k})}{n^{2k\varepsilon} \alpha^{kl}} = O(n^{1-2k\varepsilon} \log^{6k} n).
$$

This implies (3.3) in the statement of Theorem 3.1.

**7.3 Proof of (3.4) in Theorem 3.1.** Using a similar argument as in the proof of Lemma 7.1, we can prove the following estimate of $\rho(\Gamma(l,m))$. The proof is given in Appendix A.6.

**Lemma 7.2.** For $l = O(\log n)$, fixed $k$, and any $1 \leq m \leq l$, there exists a constant $C > 0$ such that

$$
\mathbb{E}_{H_n}[\rho(\Gamma(l,m))^{2k}] \leq Cn^{1-2k\alpha^{kl}(l+m-2)} \log^{14k} n.
$$

(7.17)
With Lemma 7.2, we can apply the union bound and Markov inequality. For any $\varepsilon > 0$, choose $k > 0$ such that $1 - 2k\varepsilon < 0$, we have

\[
\mathbb{P}_{\mathcal{H}_n} \left( \bigcup_{m=1}^{l} \left\{ \rho(\Gamma^{(l,m)}) \geq n^{\varepsilon - 1}\alpha^{(l+m)/2} \right\} \right) \leq \sum_{m=1}^{l} \mathbb{P}_{\mathcal{H}_n} \left( \rho(\Gamma^{(l,m)}) \geq n^{\varepsilon - 1}\alpha^{(l+m)/2} \right)
\]

\[
\leq \sum_{m=1}^{l} \frac{\mathbb{E}_{\mathcal{H}_n}(\rho(\Gamma^{(l,m)}))2k}{n^{2(k-1)}\alpha^{k(l+m)}} \leq \sum_{m=1}^{l} \frac{C\log(1+k) \cdot n^{1-2k}\alpha^{k(l+m-2)}}{n^{2(k-1)}\alpha^{k(l+m)}} = O \left( (\log(1+k) \cdot n^{1-2k}\alpha^{-2k}) \right).
\]

Since $1 - 2k\varepsilon < 0$, this proves (3.4) in Theorem 3.1.

8. Proof of Theorem 4.2

Let $n^\pm$ be the number of vertices with spin $\pm$ respectively. Consider the event

\[
\tilde{\Omega} := \{ |n^+ - n^-| \leq \log(n)\sqrt{n} \}.
\]

By Hoeffding’s inequality,

\[
\mathbb{P}_\sigma \left( |n^+ - n^-| \leq \log(n)\sqrt{n} \right) \leq 2\exp(-2\log^2(n)),
\]

which implies $\mathbb{P}_\sigma(\tilde{\Omega}) \geq 1 - 2\exp(-2\log^2(n))$. In the rest of this section we will condition on the event $\tilde{\Omega}$, which will not effect our conclusion and probability bounds, since for any event $A$, if $\mathbb{P}_{\mathcal{H}_n}(A \mid \tilde{\Omega}) = 1 - O(n^{-\gamma})$ for some $\gamma > 0$, we have

\[
\mathbb{P}_{\mathcal{H}_n}(A) = \mathbb{P}_{\mathcal{H}_n}(A \mid \tilde{\Omega})\mathbb{P}_{\mathcal{H}_n}(\tilde{\Omega}) + \mathbb{P}_{\mathcal{H}_n}(A \mid \tilde{\Omega}^c)\mathbb{P}_{\mathcal{H}_n}(\tilde{\Omega}^c) = 1 - O(n^{-\gamma}).
\]

The following identity from Equation (38) in [32] will be helpful in the proof.

Lemma 8.1. For any nonnegative integers $i, j, n$ and nonnegative numbers $a, b$ such that $a/n, b/n < 1$, we have

\[
\frac{ai + bj}{n} - \frac{1}{2} \left( \frac{ai + bj}{n} \right)^2 \leq 1 - (1 - a/n)^i(1 - b/n)^j \leq \frac{ai + bj}{n}.
\]

We will also use the following version of Chernoff bound (see [9]):

Lemma 8.2. Let $X$ be a sum of independent random variables taking values in {0, 1}. Let $\mu = \mathbb{E}[X]$. Then for any $\delta > 0$, we have

\[
\mathbb{P}(X \geq (1 + \delta)\mu) \leq \exp(-\mu h(1 + \delta)),
\]

\[
\mathbb{P}(|X - \mu| \leq \delta\mu) \geq 1 - 2\exp(-\tilde{h}(\delta)),
\]

where

\[
h(x) := x\log(x) - x + 1, \quad \tilde{h}(x) := \min\{(1 + x)\log(1 + x) - x, (1 - x)\log(1 - x) + x\}.
\]

For any $t \geq 0$, the number of vertices with spin $\pm$ at distance $t$ (respectively $\leq t$) of vertices $i$ is denoted $U^+_t(i)$ (respectively, $U^-_{\leq t}(i)$) and we know $S_t(i) = U^+_t(i) + U^-_{\leq t}(i)$. We will omit index $i$ when considering quantities related to a fixed vertex $i$. Let $n^\pm$ be the number of vertices with spin $\pm$ and $\mathcal{N}^\pm$ be the set of vertices with spin $\pm$. For a fixed vertex $i$. Let

\[
\mathcal{F}_i := \sigma(U^+_k, U^-_k, k \leq t, \sigma_i, 1 \leq i \leq n)
\]

be the $\sigma$-algebra generated by $\{U^+_k, U^-_k, 0 \leq k \leq t\}$ and $\{\sigma_i, 1 \leq i \leq n\}$. In the remainder of the section we condition on the spins $\sigma_i$ of all $i \in [n]$ and assume $\tilde{\Omega}$ holds. We denote $\mathbb{P}(\cdot) := \mathbb{P}_{\mathcal{H}_n}(\cdot \mid \tilde{\Omega})$.

A main difficulty to analyze $U^+_k, U^-_k$ compared to the graph SBM in [32] is that $U^\pm_k$ are no longer independent conditioned on $\mathcal{F}_{k-1}$. Instead, we can only approximate $U^\pm_k$ by counting subsets connected to $V_{k-1}$. To make it more precise, we have the following definition for connected-subsets.
Definition 8.3. A connected s-subset in $V_k$ for $1 \leq s \leq d-1$ is a subset of size $s$ which is contained in some hyperedge $e$ in $H$ and the rest $d-s$ vertices in $e$ are from $V_{k-1}$ (see Figure 5 for an example). Define $U_{k,r}^{(r)}$, $0 \leq r \leq s$, to be the number of connected s-subsets in $V_k$ where exactly $r$ many vertices have + spins. For convenience, we write $U_{k}^{(r)} := U_{k,d-1}^{(r)}$ for $0 \leq r \leq d-1$. Let $U_{k,s} = \sum_{r=0}^{s} U_{k,r}^{(r)}$ be the number of all connected $s$-subsets in $V_k$.

We will show that $\sum_{r=0}^{d-1} r U_{k,r}^{(r)}$ is a good approximation of $U_k^+$ and $\sum_{r=0}^{d-1} (d-1-r) U_{k}^{(r)}$ is a good approximation of $U_k^-$, then the concentration of $U_{k,r}^{(r)}$, $0 \leq r \leq d-1$ implies the concentration of $U_k^{\pm}$.

Since each hyperedge appears independently, conditioned on $F_{k-1}$, we know $\{U_{k,r}^{(r)}, 0 \leq r \leq d-1\}$ are independent binomial random variables. For $U_{k}^{(d-1)}$, the number of all possible connected $(d-1)$-subsets with $d-1$ many + signs is $\binom{n^+-U_k^+}{d-1}$, and each such subset is included in the hypergraph if and only if it forms a hyperedge with any vertex in $V_{k-1}$. Therefore each such subset is included independently with probability

$$1 - \left(1 - \frac{a}{\binom{n}{d-1}}\right)^{U_{k-1}^+} \left(1 - \frac{b}{\binom{n}{d-1}}\right)^{U_{k-1}^-}.$$

Similarly, we have the following distributions for $U_{k,r}^{(r)}$, $1 \leq r \leq d-1$:

\begin{align}
U_k^{(d-1)} &\sim \text{Bin} \left(\binom{n^+ - U_k^+}{d-1}, 1 - \left(1 - \frac{a}{\binom{n}{d-1}}\right)^{U_{k-1}^+} \left(1 - \frac{b}{\binom{n}{d-1}}\right)^{U_{k-1}^-}\right), \\
U_k^{(0)} &\sim \text{Bin} \left(\binom{n^- - U_k^-}{d-1}, 1 - \left(1 - \frac{a}{\binom{n}{d-1}}\right)^{U_{k-1}^-} \left(1 - \frac{b}{\binom{n}{d-1}}\right)^{U_{k-1}^+}\right), \\
\text{and for } 1 \leq r \leq d-2, \\
U_k^{(r)} &\sim \text{Bin} \left(\binom{n^+ - U_k^+}{r}, \binom{n^- - U_k^-}{d-1-r}, 1 - \left(1 - \frac{a}{\binom{n}{d-1}}\right)^{S_{k-1}}\right).
\end{align}

For two random variable $X, Y$, we denote $X \preceq Y$ if $X$ is stochastically dominant by $Y$, i.e., $\mathbb{P}(X \leq x) \geq \mathbb{P}(Y \leq x)$ for any $x \in \mathbb{R}$. We denote $U_k := \sum_{s=1}^{d-2} U_{k,s}$ to be the number of all connected $s$-subsets in $V_k$ for $1 \leq s \leq d-2$.

For each $1 \leq s \leq d-2$, conditioned on $F_{k-1}$, the number of possible $s$-subsets is at most $\binom{n}{s}$, and each subset is included in the hypergraph independently with probability at most $\left(\frac{a+b}{\binom{n}{d-1}}\right)^{S_{k-1}} \cdot 1$, so we have

$$U_{k,s} \preceq \text{Bin} \left(\binom{n}{s}, \frac{a+b}{\binom{n}{d-1}}^{S_{k-1}} \cdot 1\right).$$
With the definitions above, we have the following inequality for $U_k^{\pm}$ by counting the number of $\pm$ signs from each type of subsets:

$$U_k^+ \leq \sum_{r=0}^{d-1} rU_k^{(r)} + (d-2)U_k^-,$$

(8.11)

$$U_k^- \leq \sum_{r=0}^{d-1} (d-1-r)U_k^{(r)} + (d-2)U_k^+.$$

(8.12)

To obtain the upper bound of $U_k^{\pm}$, we will show that $U_k^{\pm}$ is negligible compared to the number of $\pm$ signs from $U_k^{(r)}$. Since $U_k^{(r)}$, $1 \leq r \leq d-1$ are independent binomial random variables, we can prove concentration results of these random variables. For the lower bound of $U_k^{\pm}$, we need to show that only a negligible portion of $(d-1)$ connected subsets are overlapped, therefore $U_k^{\pm}$ is lower bounded by $\sum_{r=0}^{d-1} rU_k^{(r)}$ minus some small term, and we can do it similarly for $U_k^-$. We will extensively use Chernoff bounds in Lemma 8.2 to prove the concentration of $U_k^{\pm}$ in the following theorem.

**Theorem 8.4.** Let $\varepsilon \in (0,1)$, and $l = c \log(n)$ with $c \log(\alpha) < 1/4$. For any $\gamma \in (0,3/8)$, there exists some constant $K > 0$ and such that the following holds with probability at least $1 - O(n^{-\gamma})$ for all $i \in [n]$.

1. Let $T := \inf\{t \leq l : S_t \geq K \log n\}$, then $S_T = \Theta(\log n)$.
2. Let $\varepsilon_t := \varepsilon \alpha^{-(t-T)/2}$ for some $\varepsilon > 0$ and $\alpha$.

$$M := \frac{1}{2} \left[ \begin{array}{cc} \alpha + \beta & \alpha - \beta \\ \alpha - \beta & \alpha + \beta \end{array} \right].$$

(8.13)

Then for all $t, t' \in \{T, \ldots, l\}$, $t > t'$, the vector $\vec{U}_t := (U_t^+, U_t^-)^T$ satisfies the coordinate-wise bounds:

$$U_t^+ \leq \left[ \prod_{s=t'}^{t-1} (1 - \varepsilon_s), \prod_{s=t'}^{t-1} (1 + \varepsilon_s) \right] (M^{t-t'} \vec{U}_{t'})_1,$$

(8.14)

$$U_t^- \leq \left[ \prod_{s=t'}^{t-1} (1 - \varepsilon_s), \prod_{s=t'}^{t-1} (1 + \varepsilon_s) \right] (M^{t-t'} \vec{U}_{t'})_2,$$

(8.15)

where $(M^{t-t'} \vec{U}_{t'})_j$ is the $j$-th coordinate of the vector $M^{t-t'} \vec{U}_{t'}$ for $j = 1, 2$.

**Proof.** In this proof, all constants $C_i$'s, $C, C'$ are distinct for different inequalities unless stated otherwise. By the definition of $T$, $S_{T-1} \leq K \log(n)$. Let $Z_T$ be the number of all hyperedges in $H$ that are incident to at least one vertices in $V_{T-1}$. We have $S_T \leq (d-1)Z_T$, and since the number of all possible hyperedges including a vertex in $V_{T-1}$ is at most $S_{T-1} \binom{n}{d-1}$, $Z_T$ is stochastically dominated by

$$\text{Bin} \left( K \log(n), \binom{n}{d-1} \right),$$

which has mean $(a \lor b)K \log(n)$. Let $K_1 = (a \lor b)K$. By (8.4) in Lemma 8.2, we have for any constant $K_2 > 0$,

$$\mathbb{P}(Z_T \geq K_2 \log(n)|F_{T-1}) \leq \exp(-K_1 \log(n)h(K_2/K_1))$$

(8.16)

Taking $K_2 > K_1$ large enough such that $K_1h(K_2/K_1) \geq 2 + \gamma$, we then have

$$\mathbb{P}(Z_T \geq K_2 \log(n)|F_{T-1}) \leq n^{-2-\gamma}.$$

(8.17)

So with probability at least $1 - n^{-2-\gamma}$, for a fixed $i \in [n]$, $S_T \leq K_3 \log(n)$ with $K_3 = (d-2)K_2$. Taking a union bound over $i \in [n]$, part (1) in Lemma 8.4 holds. We continue to prove (8.14) and (8.15) in several steps.

**Step 1: base case.** For the first step, we prove (8.14) and (8.15) for $t = T + 1, t' = T$, which is

$$U_{T+1}^\pm \in [1 - \varepsilon, 1 + \varepsilon] \left( \frac{\alpha + \beta}{2} U_T^\pm + \frac{\alpha - \beta}{2} U_T^\pm \right).$$

(8.18)
This involves a two-sided estimate of \( U_{T+1}^\pm \). The idea is to show the expectation of \( U_{T+1}^\pm \) conditioned on \( \mathcal{F}_T \) is close to \( \frac{\alpha+\beta}{2} U_{T+1}^+ + \frac{\alpha-\beta}{2} U_{T+1}^- \), and \( U_{T+1}^\pm \) is concentrated around its mean.

(i) **Upper bound.** Define the event \( \mathcal{A}_T := \{ S_T \leq K_3 \log n \} \). We have just shown for a fixed \( i \),

\[
(8.19) \quad \mathbb{P}(\mathcal{A}_T) \geq 1 - n^{-2-\gamma}.
\]

Recall \( |n^\pm - n/2| \leq \sqrt{n} \log n \) and conditioned on \( \mathcal{A}_T \), for some constant \( C > 0 \),

\[
U_{\leq T}^+ \leq \sum_{t=0}^T S_t \leq 1 + TK_3 \log n \leq 1 + lK_3 \log n \leq CK_3 \log^2 n.
\]

Conditioned on \( \mathcal{F}_T \) and \( \mathcal{A}_T \), for sufficiently large \( n \), there exists constants \( C_1 > 0 \) such that

\[
\left( \frac{n^+ - U_{\leq T}^+}{d - 1} \right) \geq C_1 \left( \frac{n}{d} \right).
\]

From inequality (8.3), there exists constant \( C_2 > 0 \) such that

\[
1 - \left( 1 - \frac{a}{(d-1)n} \right)^{U_T^+} \left( 1 - \frac{b}{(d-1)n} \right)^{U_T^-} \geq \frac{aU_T^+ + bU_T^-}{(d-1)n} - \frac{1}{2} \left( \frac{aU_T^+ + bU_T^-}{(d-1)n} \right)^2
\]
\[
\quad \geq \frac{C_2(aU_T^+ + bU_T^-)}{(d-1)n} \geq \frac{C_2(a \wedge b)K \log n}{(d-1)n}.
\]

Then from (8.7), for some constant \( C_3 > 0 \),

\[
\mathbb{E}[U_{T+1}^{(d-1)} | \mathcal{F}_T, \mathcal{A}_T] = \left( \frac{n^+ - U_{\leq T}^+}{d - 1} \right) \left( 1 - \left( 1 - \frac{a}{(d-1)n} \right)^{U_T^+} \left( 1 - \frac{b}{(d-1)n} \right)^{U_T^-} \right)
\]
\[
\geq C_1 \left( \frac{n}{d} \right) \frac{C_2(a \wedge b)K \log n}{(d-1)n} \geq C_3K \log n.
\]

We can choose \( K \) large enough such that \( C_3K \widehat{h}(\varepsilon/(2d)) \geq 2 + \gamma \), then from (8.5) in Lemma 8.2, for any given \( \varepsilon > 0 \) and \( \gamma \in (0,1) \),

\[
\mathbb{P} \left( \left| U_{T+1}^{(d-1)} - \mathbb{E}[U_{T+1}^{(d-1)} | \mathcal{F}_T] \right| \leq \frac{\varepsilon}{2d} \mathbb{E}[U_{T+1}^{(d-1)} | \mathcal{F}_T] \right) \geq \mathbb{P} \left( \left| U_{T+1}^{(d-1)} - \mathbb{E}[U_{T+1}^{(d-1)} | \mathcal{F}_T] \right| \leq \frac{\varepsilon}{2d} \mathbb{E}[U_{T+1}^{(d-1)} | \mathcal{F}_T], \mathcal{A}_T \right) \mathbb{P}(\mathcal{A}_T)
\]
\[
\geq \left[ 1 - \exp \left( -\mathbb{E}[U_{T+1}^{(d-1)} | \mathcal{F}_T, \mathcal{A}_T] \widehat{h}(\varepsilon/(2d)) \right) \right] (1 - n^{-2-\gamma}) \geq (1 - n^{-2-\gamma})^2 \geq 1 - 2n^{-2-\gamma}.
\]

From the symmetry of \( \pm \) labels, the concentration of \( U_{T+1}^{(0)} \) works in the same way. Similarly, there exists a constant \( C_1 > 0 \) such that \( \mathbb{E}[U_{T+1}^{(r)} | \mathcal{F}_T], 1 < r < d - 2 \):

\[
\mathbb{E}[U_{T+1}^{(r)} | \mathcal{F}_T] = \left( \frac{n^+ - U_{\leq T}^+}{r} \right) \left( \frac{n^- - U_{\leq T}^-}{d - 1 - r} \right) \left( 1 - \left( 1 - \frac{a}{(d-1)n} \right)^{S_T} \right) \geq C_1K \log n.
\]

We can choose \( K \) large enough such that for all \( 0 \leq r \leq d - 1 \),

\[
\mathbb{P} \left( \left| U_{T+1}^{(r)} - \mathbb{E}[U_{T+1}^{(r)} | \mathcal{F}_T] \right| \leq \frac{\varepsilon}{2d} \mathbb{E}[U_{T+1}^{(r)} | \mathcal{F}_T] \right) \geq 1 - 2n^{-2-\gamma}.
\]

Next, we estimate \( U_{T+1}^* = \sum_{s=1}^{d-2} U_{T+1,s} \). Recall from (8.10), we have \( U_{T+1,s} \leq Z_{T+1,s} \) where

\[
Z_{T+1,s} \sim \text{Bin} \left( \binom{n}{s}, \frac{a \lor b}{(d-1)} \binom{S_T}{d-s} \right).
\]

Conditioned on \( \mathcal{A}_T \) we know \( K \log n \leq S_T \leq K_3 \log n \), and

\[
\mathbb{E}[Z_{T+1,s} | \mathcal{A}_T, \mathcal{F}_T] = \binom{n}{s} \frac{a \lor b}{(d-1)} \binom{S_T}{d-s} \leq C_2 \log^{d-s}(n)n^{1+s-d}
\]

20
for some constant $C_2 > 0$. Using the fact that $h(x) \geq \frac{1}{2}x \log(x)$ for $x$ large enough, from (8.4), we have for any constant $\lambda > 0$, $1 \leq s \leq d - 2$, there exists a constant $C_3 > 0$ such that for large $n$,

$$
\mathbb{P}(U_{T+1,s} \geq \lambda S_T | F_T, A_T) \leq \mathbb{P}(Z_{T+1,s} \geq \lambda S_T | F_T, A_T)
$$

$$
\leq \exp \left( -\mathbb{E}[Z_{T+1,s} | A_T, F_T] h \left( \frac{\lambda S_T}{\mathbb{E}[Z_{T+1,s} | A_T, F_T]} \right) \right)
$$

(8.20)

$$
\leq \exp \left( -\frac{1}{2} \lambda S_T \log \left( \frac{\lambda S_T}{\mathbb{E}[Z_{T+1,s} | A_T, F_T]} \right) \right) \leq \exp(-\lambda C_3 \log^2 n) \leq n^{-2-\gamma}.
$$

Therefore with (8.19) and (8.20),

$$
\mathbb{P}(U_{T+1,s} < \lambda S_T | F_T) \geq \mathbb{P}(U_{T+1,s} < \lambda S_T | F_T, A_T) \mathbb{P}(A_T) \geq (1 - n^{-2-\gamma})^2 \geq 1 - 2n^{-2-\gamma}.
$$

Taking $\lambda = \frac{(\alpha - \beta)\varepsilon}{4d}$, we have $U_{T+1,s} \leq \frac{(\alpha - \beta)\varepsilon}{4d} S_T$ with probability at least $1 - 2n^{-2-\gamma}$ for any $\gamma \in (0, 1)$.

Taking a union bound over $2 \leq r \leq d - 1$, it implies

$$
U^*_{T+1} \leq \frac{(\alpha - \beta)\varepsilon}{4d} S_T
$$

with probability $1 - O(n^{-2-\gamma})$ for any $\gamma \in (0, 1)$.

Note that $n^\pm = \frac{n}{2} + O(\sqrt{n} \log n)$ and $U^\pm_{T} = \sum_{k=1}^{T} S_k = O(\log^2(n))$. From (8.3),

$$
\left( 1 - \frac{a U^+_T + b U^-_T}{2(n^\pm)} \right) \frac{a U^+_T + b U^-_T}{n^\pm} \leq 1 - \left( 1 - \frac{a}{n^\pm} \right) \frac{U^+_T}{n^\pm} \leq \frac{a U^+_T + b U^-_T}{n^\pm}.
$$

It implies that

$$
\mathbb{E}[U^{(d-1)}_{T+1} | F_T, A_T] = \left( \frac{n}{2} + O(\sqrt{n} \log n) \right) \left( 1 + O \left( \frac{\log(n)}{n^d-1} \right) \right) \frac{a U^+_T + b U^-_T}{n^\pm}.
$$

(8.22)

Similarly, for $1 \leq r \leq d - 2$,

$$
\mathbb{E}[U^{(0)}_{T+1} | F_T, A_T] = \left( \frac{1}{2d-1} + O \left( \frac{\log(n)}{n^d} \right) \right) \left( b U^+_T + a U^-_T \right),
$$

$$
\mathbb{E}[U^{(r)}_{T+1} | F_T, A_T] = \left( \frac{1}{2d-1} + O \left( \frac{\log(n)}{n^d} \right) \right) \left( \frac{d-1}{r} \right) \left( b U^+_T + a U^-_T \right).
$$

Therefore from the estimations above, with the definition of $\alpha, \beta$ from (1.3),

$$
\mathbb{E} \left[ \sum_{r=0}^{d-1} r U^{(r)}_{T+1} | F_T, A_T \right] = \left( 1 + O \left( \frac{\log(n)}{\sqrt{n}} \right) \right) \frac{1}{2d-1} \left( (d-1)(a U^+_T + b U^-_T) + \sum_{r=1}^{d-2} \left( \frac{d-1}{r} \right) b(U^+_T + U^-_T) \right).
$$

(8.23)

$$
\leq \left( 1 + O \left( \frac{\log(n)}{\sqrt{n}} \right) \right) \left( \frac{\alpha + \beta}{2} U^+_T + \frac{\alpha - \beta}{2} U^-_T \right).
$$

Since we have shown $\sum_{r=0}^{d-1} U^{(r)}_{T+1}$ concentrated around its mean by $\frac{\varepsilon}{2d}$ with probability at least $1 - O(n^{-2-\gamma})$, conditioned on $A_T$, we obtain

$$
\left| \sum_{r=0}^{d-1} r U^{(r)}_{T+1} - \mathbb{E} \sum_{r=0}^{d-1} r U^{(r)}_{T+1} | F_T \right| \leq \sum_{r=0}^{d-1} \left| U^{(r)}_{T+1} - \mathbb{E} U^{(r)}_{T+1} | F_T \right| \leq \frac{\varepsilon}{2d} \sum_{r=0}^{d-1} r \mathbb{E} U^{(r)}_{T+1} | F_T \right| \leq \frac{\varepsilon}{2d} \left( 1 + O \left( \frac{\log(n)}{\sqrt{n}} \right) \right) \left( \frac{\alpha + \beta}{2} U^+_T + \frac{\alpha - \beta}{2} U^-_T \right).
$$

(8.24)
with probability $1 - O(n^{-2-\gamma})$. Therefore from (8.23), conditioned on $A_T$, for large $n$, with probability $1 - O(n^{-2-\gamma})$,

$$
(8.25) \sum_{r=0}^{d-1} rU_{T+1}^{(r)} \in \left[1 - \frac{\varepsilon}{3}, 1 + \frac{\varepsilon}{3}\right] \left(\frac{\alpha + \beta}{2} U_T^+ + \frac{\alpha - \beta}{2} U_T^-\right).
$$

From (8.11), (8.21) and (8.25), conditioned on $A_T$ and $F_T$, with probability $1 - O(n^{-2-\gamma})$,

$$
U_{T+1}^+ \leq \sum_{r=0}^{d-1} rU_{T+1}^{(r)} + (d - 2)U_{T+1}\leq \sum_{r=0}^{d-1} rU_{T+1}^{(r)} + (d - 2)\frac{(\alpha - \beta)\varepsilon S_T}{4d} \\
\leq (1 + \varepsilon) \left(\frac{\alpha + \beta}{2} U_T^+ + \frac{\alpha - \beta}{2} U_T^-\right).
$$

Since $P(A_T) = 1 - n^{-2-\gamma}$, and by symmetry of $\pm$ labels, with probability $1 - O(n^{-2-\gamma})$,

$$
(8.26) U_{T+1}^+ \leq (1 + \varepsilon) \left(\frac{\alpha + \beta}{2} U_T^+ + \frac{\alpha - \beta}{2} U_T^-\right).
$$

\(\textbf{(ii)}\) Lower bound. To show (8.14), (8.15) for $t' = T + 1, t = T$, we cannot directly bound $U_{T+1}^\pm$ from below by $U_{T+1}^{(r)}$, $1 \leq r \leq d - 1$ since from our definition of the connected $(d - 1)$-subsets, they can overlap with each other, which leads to over-counting of the number vertices with $\pm$ labels. In the following we show the overlaps between different connected $(d - 1)$-subsets are small, which gives us the desired lower bound.

Let $W_{T+1,i}^\pm$ be the set of vertices in $V_{>T}$ with spin $\pm$ and appear in at least $i$ distinct connected $(d - 1)$-subsets in $V_{>S}$ for $i \geq 1$. Let $W_{T+1,i} = W_{T+1,i}^+ \cup W_{T+1,i}^-$. From our definition, $W_{T+1,i}^+$ are the vertices with spin $+$ that appear in at least one connected $(d - 1)$-subsets, so $|W_{T+1,i}^+| \leq U_{T+1}^+$. By counting the multiplicity of vertices with spin $+$, we have the following relation

$$
(8.27) \sum_{r=1}^{d-1} rU_{T+1}^{(r)} = |W_{T+1,i}^+| + \sum_{i \geq 2} |W_{T+1,i}^+| \leq U_{T+1}^+ + \sum_{i \geq 2} |W_{T+1,i}^-|.
$$

This implies a lower bound on $U_{T+1}^+$:

$$
(8.28) U_{T+1}^+ \geq \sum_{r=1}^{d-1} rU_{T+1}^{(r)} - \sum_{i \geq 2} |W_{T+1,i}^-|.
$$

Next we control $|W_{T+1,2}|$. Let $m = n - |V_{\leq T}|$. We enumerate all vertices in $V_{>T}$ from 1 to $m$ temporarily for the proof of the lower bound. Let $X_i, 1 \leq i \leq m$ be the random variables that $X_i = 1$ if $i \in W_{T+1,2}$ and 0 otherwise, we then have $|W_{T+1,2}| = \sum_{i=1}^{m} X_i$. A simple calculation yields

$$
(8.29) |W_{T+1,2}|^2 - |W_{T+1,2}| = \left(\sum_{i=1}^{m} X_i\right)^2 - \sum_{i=1}^{m} X_i = 2 \sum_{1 \leq i < j \leq m} X_i X_j.
$$

The product $X_i X_j$ is 1 if $i, j \in W_{T+1,2}$ and 0 otherwise.

We further consider 3 events, $E^s_{ij}$ for $s = 0, 1, 2$, where $E_{ij}^0$ is the event that all $(d - 1)$-subsets in $V_{>T}$ containing $i, j$ are not connected to $V_T$, $E_{ij}^1$ is the event that there is only one $(d - 1)$-subset in $V_{>T}$ containing $i, j$ connected to $V_T$ and $E_{ij}^2$ is the event that there are at least two $(d - 1)$-subsets in $V_{>T}$ containing $i, j$ connected to $V_T$. Now we have

$$
\mathbb{E}[X_i X_j | F_T, A_T] = P(i, j \in W_{T+1,2} | F_T, A_T) \\
= \sum_{r=0}^{2} P(i, j \in W_{T+1,2} | E_{ij}^r, F_T, A_T) P(E_{ij}^r | F_T, A_T).
$$
We estimate the three terms in the sum separately. Conditioned on $E^0_{ij}, F_T,$ and $A_T,$ the two events that $i \in W_{T+1,2}$ and $j \in W_{T+1,2}$ are independent. And the probability that $i \in W_{T+1,2}$ is bounded by

$$\left( \frac{n}{d-2} \right)^2 \left( \frac{a \lor b}{n} \right)^2 S^2_T \leq \frac{C_1 \log^2(n)}{n^2}$$

for some constant $C_1 > 0.$ So we have

$$\mathbb{P}(i, j \in W_{T+1,2} \mid E^0_{ij}, F_T, A_T) \mathbb{P}(E^0_{ij} \mid F_T, A_T) \leq \mathbb{P}(i, j \in W_{T+1,2} \mid E^0_{ij}, F_T, A_T)$$

(8.31)

$$= \mathbb{P}(i \in W_{T+1,2} \mid E^0_{ij}, F_T, A_T) \mathbb{P}(j \in W_{T+1,2} \mid E^0_{ij}, F_T, A_T) \leq \frac{C_1 \log^2 n}{n^4}.$$

For the term that involves $E^1_{ij},$ we know for some $C_2 > 0,$

$$\mathbb{P}(E^1_{ij} \mid F_T, A_T) \leq \left( \frac{n}{d-3} \right) \frac{a \lor b}{n} S_T \leq \frac{C_2 \log n}{n^2},$$

and conditioned on $E^1_{ij}$ and $F_T, A_T,$ the two events that $i \in W_{T+1,2}$ and $j \in W_{T+1,2}$ are independent again, since we require $i, j$ to be contained in at least 2 connected subsets. We have

$$\mathbb{P}(i \in W_{T+1,2} \mid E^1_{ij}, F_T, A_T) \leq \left( \frac{n}{d-2} \right) \frac{a \lor b}{n} S_T \leq \frac{C_2 \log n}{n^2}.$$

Therefore we have

$$\mathbb{P}(i, j \in W_{T+1,2} \mid E^1_{ij}, F_T, A_T) \mathbb{P}(E^1_{ij} \mid F_T, A_T)$$

$$= \mathbb{P}(i \in W_{T+1,2} \mid E^1_{ij}, F_T, A_T) \mathbb{P}(j \in W_{T+1,2} \mid E^1_{ij}, F_T, A_T) \mathbb{P}(E^1_{ij} \mid F_T, A_T)$$

(8.32)

$$\leq \frac{C_2 \log^2 n}{n^2} \cdot \frac{C_2 \log n}{n^2} = \frac{C_2 \log^3 n}{n^4}.$$

Conditioned on $E^2_{ij}, i, j$ have already been included in 2 connected $(d-1)$ subsets, so

$$\mathbb{P}(i, j \in W_{T+1,2} \mid E^2_{ij}, F_T, A_T) = 1.$$

We then have for some $C_3 > 0,$

$$\mathbb{P}(i, j \in W_{T+1,2} \mid E^2_{ij}, F_T, A_T) \mathbb{P}(E^2_{ij} \mid F_T, A_T)$$

(8.33)

$$= \mathbb{P}(E^2_{ij} \mid F_T, A_T) \leq \left( \frac{n}{d-3} \right)^2 \frac{a \lor b}{n} S^2_T \leq \frac{C_3 \log^2 n}{n^4}.$$

Combining (8.31)-(8.33), we have for some constant $C' > 0,$

(8.34)

$$\mathbb{E}[X_i X_j \mid F_T, A_T] \leq \frac{C' \log^4 n}{n^4}.$$

Taking conditional expectation in (8.29), we have

$$\mathbb{E}[|W_{T+1,2}|^2 - |W_{T+1,2}| \mid F_T, A_T] = 2 \sum_{1 \leq i < j \leq n} \mathbb{E}[X_i X_j \mid F_T, A_T] \leq \frac{C' \log^4 n}{n^2}.$$

By Markov’s inequality, there exists a constant $C > 0$ such that for any constant $\lambda > 0$ and sufficiently large $n,$

$$\mathbb{P}(|W_{T+1,2}| > \lambda S_T \mid F_T, A_T) \leq \mathbb{P}(|W_{T+1,2}|(|W_{T+1,2}| - 1) > \lambda S_T(\lambda S_T - 1) \mid F_T, A_T)$$

$$\leq \frac{\mathbb{E}(|W_{T+1,2}|(|W_{T+1,2}| - 1) \mid F_T, A_T)}{\lambda S_T(\lambda S_T - 1)} \leq \frac{C \log^2 n}{\lambda^2 n^2},$$

where in the last inequality we use the fact that $S_T \geq K \log n.$ Taking $\lambda = \frac{(\alpha - \beta) \varepsilon}{4},$ we have for all large $n$ and for any $\gamma \in (0, 1),$

$$\mathbb{P}

(8.36)

\begin{align*}
\mathbb{P} \left( |W_{T+1,2}| > \frac{(\alpha - \beta) \varepsilon}{4} S_T \mid F_T, A_T \right) &= O \left( \frac{\log^2 n}{n^2} \right) \leq n^{-1-\gamma}.
\end{align*}
For a fixed vertex \( j \in V_{>T} \), the probability that \( j \in W_{T+1,i} \) is at most \( \left( \frac{n}{d-2} \right)^i S_T \left( \frac{\alpha \vee b}{\binom{n}{d-1}} \right)^i \), then we have for sufficiently large \( n \),

\[
E[|W_{T+1,i}| \mid F_T, A_T] \leq n \left( \frac{n}{d-2} \right)^i S_T \left( \frac{\alpha \vee b}{\binom{n}{d-1}} \right)^i \leq n \left( \frac{C_4 \log n}{n} \right)^i
\]

for some \( C_4 > 0 \). For the rest of the terms in (8.27), we have for some constant \( C > 0 \),

\[
E \left[ \sum_{i \geq 3} |W_{T+1,i}| \mid F_T, A_T \right] \leq n \sum_{i=3}^{\infty} \left( \frac{C_4 \log n}{n} \right)^i \leq C \log^3(n) \frac{n}{n^2}.
\]

By Markov’s inequality,

\[
P \left( \sum_{i \geq 3} |W_{T+1,i}| \geq \frac{(\alpha - \beta) \varepsilon}{4} S_T \mid F_T, A_T \right) \leq C \log^2(n) \frac{n}{n^2} \leq n^{-1-\gamma}.
\]

Together with (8.36), we have conditioned on \( A_T \), \( \sum_{i \geq 2} |W_{T+1,i}| \leq \frac{(\alpha - \beta) \varepsilon}{2} S_T \) with probability at least \( 1 - 2n^{-1-\gamma} \) for any \( \gamma \in (0, 1) \) and all large \( n \). Note that

\[
\frac{(\alpha - \beta) \varepsilon}{2} S_T \leq \frac{\varepsilon}{2} \left( \frac{\alpha + \beta}{2} U_T^+ + \frac{\alpha - \beta}{2} U_T^- \right).
\]

With (8.25), (8.28), and (8.19), we have

\[
U_{T+1}^+ \geq \sum_{r=1}^{d-1} rU_{T+1}^r - \frac{\varepsilon}{2} \left( \frac{\alpha + \beta}{2} U_T^+ + \frac{\alpha - \beta}{2} U_T^- \right) \geq (1 - \varepsilon) \left( \frac{\alpha + \beta}{2} U_T^+ + \frac{\alpha - \beta}{2} U_T^- \right)
\]

with probability \( 1 - O(n^{-1-\gamma}) \). By symmetry, the argument works for \( U_{T+1}^- \), therefore with probability \( 1 - O(n^{-1-\gamma}) \) for any \( \gamma \in (0, 1) \), we have

\[
U_{T+1}^\pm \geq (1 - \varepsilon) \left( \frac{\alpha + \beta}{2} U_T^\pm + \frac{\alpha - \beta}{2} U_T^\mp \right).
\]

From (8.26) and (8.37), we have with probability \( 1 - O(n^{-1-\gamma}) \) for any \( \gamma \in (0, 1) \), (8.18) holds.

**Step 2: Induction.** It remains to extend this estimate in Step 1 for all \( T \leq t' < t \leq l \). We now define the event

\[
A_t := \left\{ U_t^\pm \in [1 - \varepsilon_{t-1}, 1 + \varepsilon_{t-1}] \left( \frac{\alpha + \beta}{2} U_{t-1}^+ + \frac{\alpha - \beta}{2} U_{t-1}^- \right) \right\}
\]

for \( T + 1 \leq t \leq l \), and recall \( \varepsilon_t = \varepsilon \alpha^{-(t-T)/2} \), \( A_T = \{ S_T \leq K_3 \log n \} \).

From the proof above, we have shown \( A_{T+1} \) holds with probability \( 1 - O(n^{-1-\gamma}) \). Conditioned on \( A_T \), \( A_{T+1}, \ldots, A_t \), for some fix \( t \) with \( T + 2 \leq t \leq l \), the vector \( \tilde{U}_t = (U_t^+, U_t^-) \) satisfies (8.14), (8.15) for any \( T \leq t' < t \).

Set \( t' = T + 1 \). From [32], for any integer \( k > 0 \), \( M^k = \frac{1}{2} \left[ \begin{array}{ccc} \alpha^k + \beta^k & \alpha^k - \beta^k \\ \alpha^k - \beta^k & \alpha^k + \beta^k \end{array} \right] \). (8.14) implies that

\[
U_t^\pm \geq \left( \sum_{s=1}^{t-1} (1 - \varepsilon_s) \left( \frac{\alpha^{t-T-1} + \beta^{t-T-1}}{2} U_{T+1}^\pm + \frac{\alpha^{t-T-1} - \beta^{t-T-1}}{2} U_{T+1}^- \right) \right) \geq (1 - O(\varepsilon)) \frac{\alpha^{t-T-1}}{2} (1 - \varepsilon) \left( \frac{\alpha + \beta}{2} U_T^+ + \frac{\alpha - \beta}{2} U_T^- \right)
\]

\[
\geq (1 - O(\varepsilon)) \alpha^{t-T} \left( 1 - \varepsilon \right) \left( \frac{\alpha - \beta}{4\alpha} \right) S_T \geq C_1 \alpha^{t-T} \log(n),
\]

(8.39)
for some constant $C_1 > 0$. For any $t$ with $T \leq t$, conditioned on $A_T, A_{T+1}, \ldots, A_t$, since $\beta < \alpha$,

$$
U_t^\pm \leq \left( \prod_{s=T}^{t-1} (1 + \varepsilon_s) \right) \left( \frac{\alpha^{t-T} + \beta^{t-T}}{2} U_T^\pm + \frac{\alpha^{t-T} - \beta^{t-T}}{2} U_T^\pm \right)
$$

(8.40)

$$
\leq (1 + O(\varepsilon)) \frac{\alpha^{t-T} + \beta^{t-T}}{2} S_T \leq (1 + O(\varepsilon)) \alpha^{t-T} K_3 \log(n) \leq C_2 \alpha^{t-T} \log n
$$

for some $C_2 > 0$. Combining lower and upper bounds on $U_t^\pm$, we obtain

(8.41)

$$
S_t = U_t^+ + U_t^- = \Theta(\alpha^{t-T} \log n).
$$

We now show by induction that $A_{t+1}$ holds with high enough probability conditioned on $\{A_j, T \leq j \leq t\}$.

(i) **Upper bound.** Note that $\alpha^i = o(n^{1/4})$, for some constant $C > 0$

$$
U_{t+1}^\pm \leq \sum_{i=1}^t S_i \leq C \alpha^{t-T} \log^2 n \leq C \alpha^t \log n = o(n^{1/4} \log n).
$$

Recall $|n^\pm - \frac{n}{2}| \leq \sqrt{n} \log n$. From (8.7)-(8.9), similar to the case for $t = T$, we have

$$
E[U_{t+1}^{(d-1)} | \cap_{j=T}^t A_j, F_t] = \left( n^+ - U_{t+1}^+ \right) \left( 1 - \left( 1 - \frac{a}{n} \right)^{d-1} \right) \left( 1 - \frac{b}{(d-1)} \right)
$$

and

$$
E[U_{t+1}^{(0)} | \cap_{j=T}^t A_j, F_t] = \left( \frac{1}{2d-1} + O(\log n) \right) (aU_t^+ + bU_t^-),
$$

and

$$
E[U_{t+1}^{(r)} | \cap_{j=T}^t A_j, F_t] = \left( \frac{1}{2d-1} + O(\log n) \right) (d-1) (bU_t^+ + bU_t^-),
$$

for $1 \leq r \leq d-2$. Hence there exists a constant $C_0 > 0$ such that for all $0 \leq r \leq d-1$,

$$
E[U_{t+1}^{(r)} | \cap_{j=T}^t A_j, F_t] \geq C_0 S_t.
$$

From (8.5) in Lemma 8.2, for any $0 \leq r \leq d-1$, to show

(8.42)

$$
P \left( \left| U_{t+1}^{(r)} - E[U_{t+1}^{(r)} | \cap_{j=T}^t A_j, F_t] \right| \leq \frac{\varepsilon}{2d} E[U_{t+1}^{(r)} | \cap_{j=T}^t A_j, F_t] \mid \cap_{j=T}^t A_j, F_t \right) \geq 1 - n^{-2-\gamma},
$$

it suffices to have

(8.43)

$$
C_0 S_t \tilde{h} \left( \frac{\varepsilon}{2d} \right) \geq (2 + \gamma) \log n.
$$

From (8.5), by a second-order expansion of $\tilde{h}$ around $0$, $\tilde{h}(x) \geq x^2/3$ when $x > 0$ is small. For $\gamma \in (0, 1)$, the left hand side in (8.43) is lower bounded by

$$
C_1 K \alpha^{t-T} \log(n) \tilde{h} \left( \frac{\varepsilon}{2d} \right) \geq C_2 \alpha^{t-T} K \log(n) \varepsilon_t^2 = C_2 K \log n \geq (2 + \gamma) \log n,
$$

by taking $K$ large enough. Therefore (8.42) holds.

We also have

$$
U_{t+1,s} \leq Z_{t+1,s}, \quad Z_{t+1,s} \sim \text{Bin} \left( \left( \frac{n}{s} \right), \frac{a \vee b}{d-1} \right),
$$

and $Z_{t+1,s}$ has mean $(n) \frac{a \vee b}{d-1} (S_t) = \Theta \left( \frac{\alpha^{(d-s)(t-T)} \log^{d-s}(n)}{n^{(d-s)(t-T)}} \right)$. For $1 \leq s \leq d-2$, using the fact that $h(x) \geq x \log(x)$ for $x$ large enough, similar to (8.20), there are constants $C_1, C_2, C_3, C_4 > 0$ such that for
any \( \lambda > 0 \),
\[
\mathbb{P}(U_{t+1,s} \geq \lambda S_t \mid \cap_{j=T}^t A_j, \mathcal{F}_t) \leq \mathbb{P}(Z_{t+1,s} \geq \lambda S_t \mid \cap_{j=T}^t A_j, \mathcal{F}_t)
\]
\[
\leq \exp \left( -C_1 \lambda \alpha^{-T} \log(n) \log \left( \frac{C_2 \lambda \alpha^{t-T} \log(n)}{C_3 \alpha^{(d-s)(t-T) \log^{d-s}(n)n^{1+s-d}}} \right) \right).
\]
Taking \( \lambda = \frac{(\alpha - \beta)\eps_t}{4d^2} = \frac{(\alpha - \beta)\alpha^{-(t-T)/2}}{4d^2} \), we have
\[
\mathbb{P} \left( U_{t+1,s} \geq \frac{(\alpha - \beta)\eps_t}{4d^2} S_t \mid \cap_{j=T}^t A_j, \mathcal{F}_t \right)
\]
\[
\leq \exp \left( -C_1' \alpha^{-(t-T)/2} \log(n) \cdot \log(C_2' \alpha^{(s-d+\frac{1}{2})(t-T) \log^{1+s-d}(n)n^{d-1-s}}) \right).
\]
Since for some constants \( C_4, C_5, C_6 > 0 \),
\[
\log(C_2' \alpha^{(s-d+\frac{1}{2})(t-T) \log^{1+s-d}(n)n^{d-1-s}})
\]
\[
\geq C_4 - C_5(t - T) \log(\alpha) + \log(\log^{1+s-d}(n)) + (d - 1 - s) \log n \geq C_6 \log n,
\]
we have for all \( 1 \leq s \leq d - 2 \),
\[
(8.44) \quad \mathbb{P}(U_{t+1,s} \geq \frac{(\alpha - \beta)\eps_t}{4d^2} S_t \mid \cap_{j=T}^t A_j, \mathcal{F}_t) \leq \exp \left( -C_1' C_6 \log^2 n \right) \leq n^{-2-\gamma}
\]
for any \( \gamma \in (0, 1) \). Recall for sufficiently large \( n \),
\[
\eps_t = \eps \alpha^{-(t-T)/2} \geq \eps \alpha^{-1/2} > n^{-1/8}.
\]
Therefore \( \log \frac{n}{\sqrt{n}} = o(\eps_t) \). From (8.44), conditioned on \( A_T, \ldots, A_t \) and \( \mathcal{F}_t \),
\[
U_{t+1}^+ \leq \sum_{r=1}^{d-1} r U_{t+1}^{(r)} + (d - 2)U_{t+1}^- \leq (1 + \eps_t) \left( \frac{\alpha + \beta}{2} U_t^+ + \frac{\alpha - \beta}{2} U_t^- \right)
\]
with probability at least \( 1 - O(n^{-2-\gamma}) \). A similar bound works for \( U_{t+1}^- \), which implies conditioned on \( A_T, \ldots, A_t \),
\[
(8.45) \quad U_{t+1}^\pm \leq (1 + \eps_t) \left( \frac{\alpha + \beta}{2} U_t^+ + \frac{\alpha - \beta}{2} U_t^- \right)
\]
with probability \( 1 - O(n^{-2-\gamma}) \) for any \( \gamma \in (0, 1) \).

(ii) **Lower bound.** We need to show that conditioned on \( A_T, \ldots, A_t \), \( U_{t+1}^+ \geq (1-\eps_t) \left( \frac{\alpha + \beta}{2} U_t^+ + \frac{\alpha - \beta}{2} U_t^- \right) \)
with probability \( 1 - O(n^{-1-\gamma}) \) for some \( \gamma \in (0, 1) \). This part of the proof is very similar to the case for \( t = T \). Same as (8.28), we have the following lower bound on \( U_{t+1}^+ \):
\[
U_{t+1}^+ \geq \sum_{r=1}^{d-1} r U_{t+1}^{(r)} - \sum_{i \geq 2} |W_{t+1,i}|.
\]

Next we control \( |W_{t+1,2}| \). Let \( m = n - |V_{\leq t}| \) and we enumerate all vertices in \( V_{>t} \) from 1 to \( m \). Let \( X_1, \ldots, X_m \) be the random variable that \( X_i = 1 \) if \( i \in W_{t+1,2} \) and 0 otherwise. Same as (8.29),
\[
(8.46) \quad |W_{t+1,2}|^2 - |W_{t+1,2}| = 2 \sum_{1 \leq i < j \leq m} X_i X_j.
\]

Let \( E_{ij}^s \) for \( s = 0, 1, 2 \), be the similar events as in (8.30) before, now we have
\[
\mathbb{E}[X_i X_j \mid \cap_{j=T}^t A_j, \mathcal{F}_t] = \mathbb{P}(i, j \in W_{t+1,2} \mid \cap_{j=T}^t A_j, \mathcal{F}_t)
\]
\[
= \sum_{r=0}^{2} \mathbb{P}(i, j \in W_{t+1,2} \mid E_{ij}^r, \cap_{j=T}^t A_j, \mathcal{F}_t) \mathbb{P}(E_{ij}^r \mid \cap_{j=T}^t A_j, \mathcal{F}_t).
\]
The three terms in the sum can be estimated separately in the same way as before. By using the upper bound $C\alpha ^{t-T} \log n \leq S_t \leq C_0 \alpha ^{t-T} \log n$ for some $C, C_0 > 0$, and use the same argument for the case when $t = T$, we have the following three inequalities for some constants $C_1, C_2, C_3 > 0$:

\[
P(i, j \in W_{t+1, 2} | E_{ij}^0, F_t) \mathbb{P}(E_{ij}^0 \mid \cap_{j=T}^t A_j, F_t) \leq \frac{C_1^2 \alpha ^{4(t-T)} \log^4 n}{n^4},
\]

\[
P(i, j \in W_{t+1, 2} \mid E_{ij}^1, F_t) \mathbb{P}(E_{ij}^1 \mid \cap_{j=T}^t A_j, F_t) \leq \frac{C_2^3 \alpha ^{3(t-T)} \log^3 n}{n^4},
\]

\[
P(i, j \in W_{t+1, 2} \mid E_{ij}^2, F_t) \mathbb{P}(E_{ij}^2 \mid \cap_{j=T}^t A_j, F_t) \leq \frac{C_3^2 \alpha ^{2(t-T)} \log^2 n}{n^4}.
\]

This implies $E[X_i X_j \mid \cap_{j=T}^t A_j, F_t] \leq \frac{C' \alpha ^{4(t-T)} \log^4 n}{n^2}$ for some $C' > 0$. Taking conditional expectation in (8.46), we have

\[
E \left[ |W_{t+1, 2}|^2 - |W_{t+1, 2}| \mid \cap_{j=T}^t A_j, F_t \right] \leq \frac{C' \alpha ^{4(t-T)} \log^4 n}{n^2}.
\]

Then by Markov inequality and (8.41), similar to (8.35), there exists a constant $C > 0$ such that for any $\lambda = \Omega(\alpha ^{-(t-T)})$,

\[
P \left( |W_{t+1, 2}| > \lambda S_t \mid \cap_{j=T}^t A_j, F_t \right) \leq \frac{C \alpha ^{2(t-T)} \log^2 n}{\lambda^2 n^2} \leq n^{-1-\gamma}
\]

for any $\gamma \in (0, 1/2)$.

For each $|W_{t+1,i}|$ for $i \geq 3$, we have for sufficiently large $n$, there exists a constant $C_4 > 0$

\[
E[|W_{t+1,i}| \mid \cap_{j=T}^t A_j, F_t] \leq \sum_{i=3}^n \left( \frac{C_4 \alpha ^{4(t-T)} \log n}{n} \right)^i \leq \frac{C_4' \alpha ^{3(t-T)} \log^3(n)}{n^2}.
\]

For the rest of the terms, we have for some constant $C'_4 > 0$,

\[
E \left[ \sum_{i \geq 3} |W_i| \mid \cap_{j=T}^t A_j, F_t \right] \leq \sum_{i=3}^n \left( \frac{C_4 \alpha ^{4(t-T)} \log n}{n} \right)^i \leq \frac{C_5 \alpha ^{2.5(t-T)} \log^2(n)}{n^2} \leq n^{-1-\gamma}
\]

for any $\gamma \in (0, 3/8)$. Together with the estimate on $W_{t+1, 2}$, we have

\[
\sum_{i \geq 2} |W_{t+1, 2}| \leq \left( \frac{\alpha - \beta}{2} \right) S_t \leq \frac{\varepsilon_t}{2} \left( \frac{\alpha + \beta}{2} \right) U_1^+ + \frac{\alpha - \beta}{2} U_1^-)
\]

with probability $1 - 2n^{-1-\gamma}$ for any $\gamma \in (0, 3/8)$.

With (8.28) and (8.25), $U_{t+4}^+ \geq (1 - \varepsilon_t) \left( \frac{\alpha + \beta}{2} \right) U_t^+ + \frac{\alpha - \beta}{2} U_t^-$ with probability $1 - O(n^{-1-\gamma})$. By symmetry, the argument works for $U_{t+1}^-$. Therefore conditioned on $A_T, \ldots, A_t$, with probability $1 - O(n^{-1-\gamma})$ for any $\gamma \in (0, 3/8)$,

\[
U_{t+1}^+ \geq (1 - \varepsilon_t) \left( \frac{\alpha + \beta}{2} U_t^+ + \frac{\alpha - \beta}{2} U_t^- \right).
\]

This finishes the proof the lower bound part of Step 2.
Recall (8.38). With (8.47) and (8.45), we have shown that conditioned on $A_{t}, \ldots, A_{l}$, with probability $1 - O(n^{-1-\gamma})$, $A_{t+1}$ holds. This finishes the induction step. Finally, for fixed $i \in [n]$ and $\gamma \in (0, 3/8)$,

$$P \left( \bigcap_{t=T}^{l} A_{t} \right) = P(A_{T}) \prod_{t=T+1}^{l} P(A_{t} \mid A_{t-1}, \ldots, A_{T}) \geq (1 - Cn^{-2-\gamma})(1 - Cn^{-1-\gamma})t \geq 1 - C_{0} \log(n)n^{-1-\gamma},$$

for some constant $C_{0} > 0$. Taking a union bound over $i \in [n]$, we have shown $A_{t}$ holds for all $T \leq t \leq l$ and all $i \in [n]$ with probability $1 - O(n^{-\gamma})$ for any $\gamma \in (0, 3/8)$. This completes the proof of Theorem 8.4. □

With Theorem 8.4, the rest of the proof of Theorem 4.2 follows similarly from the proof of Theorem 2.3 in [32]. We include it for completeness.

**Proof of Theorem 4.2.** Assume all the estimates in statement of Theorem 8.4 hold. For $t \leq l$, if $t \leq T$, from the definition of $T$, we have $S_{t}, |D_{t}| = O(\log n)$. For $t > T$, from [32], $M$ satisfies

$$M^{k} = \frac{1}{2} \left[ \alpha^{k} + \beta^{k} \right].$$

Using (8.14) and (8.15), we have for $t > t' \geq T$,

$$S_{t} \leq \left( \prod_{s=t'}^{t-1} (1 + \varepsilon_{s}) \right) (1, 1)M^{t-t'} \tilde{U}_{t'} \leq \left( \prod_{s=t'}^{t-1} (1 + \varepsilon_{s}) \right) \alpha^{t-t'} S_{t'}, \tag{8.48}$$

$$S_{t} \geq \left( \prod_{s=t'}^{t-1} (1 - \varepsilon_{s}) \right) (1, 1)M^{t-t'} \tilde{U}_{t'} \geq \left( \prod_{s=t'}^{t-1} (1 - \varepsilon_{s}) \right) \alpha^{t-t'} S_{t'}. \tag{8.49}$$

Setting $t' = T$ in (8.48), we obtain

$$S_{t} \leq \left( \prod_{s=T}^{t-1} (1 + \varepsilon_{s}) \right) \alpha^{t-T} S_{T} = O(\alpha^{t-T} \log n) = O(\alpha^{t} \log n).$$

Therefore (4.1) holds. Let $t = l$ in (8.48) and (8.49), we have for all $T \leq t' < l$, 

$$\left( \prod_{s=t'}^{t-1} (1 - \varepsilon_{s}) \right) \alpha^{t-t'} S_{t'} \leq S_{t} \leq \left( \prod_{s=t'}^{t-1} (1 + \varepsilon_{s}) \right) \alpha^{t-t'} S_{t'}.$$ 

And it implies

$$\left( \prod_{s=t'}^{t-1} (1 - \varepsilon_{s}) \right) S_{t'} \leq \alpha^{t'-1} S_{t'} \leq \left( \prod_{s=t'}^{t-1} (1 + \varepsilon_{s}) \right) S_{t'}. \tag{8.50}$$

Note that

$$\max \left\{ \left( \prod_{s=t'}^{t-1} (1 + \varepsilon_{s}) \right) - 1, 1 - \left( \prod_{s=t'}^{t-1} (1 - \varepsilon_{s}) \right) \right\} = O(\varepsilon_{t'}) = O(\alpha^{-t'/2}).$$

Together with (8.50), we have for all $T \leq t' < l$,

$$|S_{t'} - \alpha^{t'-1} S_{t'}| \leq O(\alpha^{-t'/2}) S_{t'} = O(\alpha^{t'/2} \log n). \tag{8.51}$$

On the other hand, for $t \leq T$, we know $S_{t} = O(\log n)$. Let $t' = T$ in (8.51), we have

$$|S_{T} - \alpha^{T-1} S_{t'}| = O(\alpha^{T/2} \log n). \tag{8.52}$$

So for $1 \leq t \leq T$,

$$|S_{t} - \alpha^{t-1} S_{t}| = O(\log n) + \alpha^{t-T} (S_{t} + O(\log(n)\alpha^{T/2}))$$

$$= O(\log n) + O(\alpha^{t-T/2} \log n) = O(\alpha^{t/2} \log n). \tag{8.53}$$

The last inequality comes from the inequality $t - T/2 \leq t/2$. Combining (8.51) and (8.53), we have proved (4.3) holds for all $1 \leq t \leq l$. 

28
Using (8.14) and (8.15), we have
\[ D_{t+1} = U_{t+1}^+ - U_{t+1}^- \leq \beta(U_t^+ - U_t^-) + \alpha \varepsilon_t(U_t^+ + U_t^-) = \beta D_t + \alpha \varepsilon_t S_t. \]
Similarly, \( \beta D_t - \alpha \varepsilon_t S_t \leq D_{t+1} \leq \beta D_t + \alpha \varepsilon_t S_t. \) By iterating, we have for \( l \geq t > t' \geq T, \)
\[ (9.54) \quad |D_t - \beta^{t-t'} D_{t'}| \leq \sum_{s=t'}^{t-1} \alpha \beta^{t-1-s} \varepsilon_s S_s. \]
Recall \( S_s = O(\log(n) \alpha^{s-T}), |D_T| = O(\log n), \) and \( \varepsilon_s = \alpha^{-\log n}. \) Taking \( t' = T \) in (8.54), for \( t > T, \)
\[ |D_t| = O(\log(n) \beta^t) + O\left( \sum_{s=T}^{t-1} \alpha \beta^{t-1-s} \log(n) \alpha^{(s-T)/2} \right). \]
Since \( 1 < \alpha < \beta^2, \) it follows that
\[ \sum_{s=T}^{t-1} \alpha \beta^{t-1-s} \log(n) \alpha^{(s-T)/2} = \beta^{t-1} \alpha^{1-T/2} \log(n) \sum_{s=T}^{t-1} (\alpha / \beta^2)^{s/2} = \beta^{t-1} \alpha^{1-T/2} \log(n) O(\alpha^{T/2} \beta^{T/2}) = O(\log(n) \beta^t). \]
So we have \( |D_t| = O(\log(n) \beta^t) \). The right side of (8.54) is of order
\[ \sum_{s=T}^{t-1} \alpha \beta^{t-1-s} \alpha^{(s-T)/2} \log(n) = O(\log(n) \beta^{t-t'} \alpha^T/2). \]
Thus setting \( t = l \) in (8.54), for \( l > t' \geq T, \) we obtain \( D_t - \beta^{t-t'} D_{t'} = O(\log(n) \beta^{l-t'} \alpha^T/2). \) Therefore \( D_t = \beta^{t-t} D_t + O(\log(n) \alpha^{T/2}) \) holds for all \( T \leq t' < l. \) For \( t' < T, \) we have \( D_{t'} = O(\log(n) \alpha^{T/2}) \) and
\[ |D_{t'} - \beta^{t'-T} D_{t}| \leq O(\log(n) + \beta^{t'-T} (|D_T| + O(\log(n) \alpha^{T/2}))) = O(\log(n) + O(\beta^{t'-T} \alpha^{T/2} \log n)) = O(\alpha^{T/2} \log n), \]
where the last estimate is because \( \beta^{t'-T} < \alpha^{(t'-T)/2} \) under the condition that \( t' < T. \) Altogether we have shown (4.4) holds for all \( 1 \leq t' \leq l. \) This completes the proof of Theorem 4.2. \( \square \)

9. Proof of Theorem 4.6

We first state the following lemma before proving Theorem 4.6. The proof is included in Appendix A.7.

**Lemma 9.1.** For all \( m \in \{1, \ldots, l\} \) with \( c \log n, \log \alpha < 1/4, \) it holds asymptotically almost surely that
\[ (9.1) \quad \sup_{\|x\|_2 = 1} \mathbb{E}[B^{(m-1)}_1 x]_2 = O(\sqrt{n} \alpha^{(m-1)/2} \log n), \]
\[ (9.2) \quad \sup_{\|x\|_2 = 1} \mathbb{E}[\sigma \mathbb{E}[B^{(m-1)}_1 x]_2 = O(\sqrt{n} \alpha^{(m-1)/2} \log n). \]

**Proof of Theorem 4.6.** Using matrix expansion identity (3.2) and the estimates in Theorem 3.1, for any \( l_2 \)-normalized vector \( x \) with \( x^T B^{(l)}_1 = x^T B^{(l)}_1 \sigma = 0, \) we have for sufficiently large \( n, \) asymptotically almost surely
\[ \|B^{(l)} x\|_2 = \left\| \Delta^{(l)} x + \sum_{m=1}^l (\Delta^{(l-m)} \bar{A} B^{(m-1)} x - \sum_{m=1}^l \Gamma^{(l,m)} x) \right\|_2 \leq \rho(\Delta^{(l)}) + \sum_{m=1}^l \rho(\Delta^{(l-m)}) \|\bar{A} B^{(m-1)} x\|_2 + \sum_{m=1}^l \rho(\Gamma^{(l,m)}) \leq 2n \alpha^{l/2} + \sum_{m=1}^l n^2 \alpha^{(l-m)/2} \|\bar{A} B^{(m-1)} x\|_2, \]
(9.3)
where $\bar{A} = \mathbb{E}_{\mathcal{H}_n} [A \mid \sigma]$. We have the following expression for entries of $\bar{A}$. If $i \neq j$ and $\sigma_i = \sigma_j = 1$,

$$
\bar{A}_{ij} = \frac{a}{d-1} \left( \frac{n^+ - 2}{d - 2} \right) + \frac{b}{\binom{n}{d-1}} \left( \frac{n - 2}{d - 2} \right) =: \bar{a}^+.
$$

If $i \neq j$ and $\sigma_i = \sigma_j = -1$,

$$
\bar{A}_{ij} = \frac{a}{d-1} \left( \frac{n^+ - 2}{d - 2} \right) + \frac{b}{\binom{n}{d-1}} \left( \frac{n - 2}{d - 2} \right) =: \bar{a}^-.
$$

If $\sigma_i \neq \sigma_j$,

$$
\bar{A}_{ij} = \frac{b}{\binom{n}{d-1}} \left( \frac{n - 2}{d - 2} \right) := \tilde{b}_n.
$$

We then have $\bar{a}^+, \bar{a}^-, \tilde{b}_n = O(1/n)$. Conditioned on the event $\{|n^+ - n/2| \leq \log(n)/\sqrt{n}\}$, we obtain

$$
\bar{a}^+ - \bar{a}^- = \frac{a - b}{\binom{n}{d-1}} \left( \frac{n - 2}{d - 2} \right) = O\left( \frac{\log n}{n^{3/2}} \right).
$$

Let $R$ be a $n \times n$ matrix such that

$$
R_{ij} = \begin{cases} 
1 & \sigma_i = \sigma_j = -1 \text{ and } i \neq j, \\
0 & \text{otherwise}.
\end{cases}
$$

We then have $\|R\|_2 \leq \sqrt{\sum_{ij} R_{ij}^2} \leq n$. The following decomposition of $\bar{A}$ holds:

(9.4) \[ \bar{A} = \bar{a}^+ \left[ \frac{1}{2} (1 \cdot 1^T + \sigma \sigma^T) - I \right] + \frac{\tilde{b}_n}{2} (1 \cdot 1^T - \sigma \sigma^T) + (\bar{a}^+ - \bar{a}^-) R \]

(9.5) \[ = \bar{a}^+ + \frac{\tilde{b}_n}{2} 1 \cdot 1^T + \frac{\bar{a}^+ - \bar{a}^-}{2} \sigma \sigma^T + ((\bar{a}^+ - \bar{a}^-) R - \bar{a}^+ I). \]

Since

$$
\| (\bar{a}^+ - \bar{a}^-) R - \bar{a}^+ I \|_2 \leq |\bar{a}^+ - \bar{a}^-| \cdot \|R\|_2 + |\bar{a}^+| = O(\log n/\sqrt{n}),
$$

by (9.5), we have

$$
\| \bar{A} B^{(m-1)} x \|_2 = O\left( \frac{1}{n} \right) \| 1 \cdot 1^T B^{(m-1)} x \|_2 + O\left( \frac{1}{n} \right) \| \sigma \sigma^T B^{(m-1)} x \|_2 + O\left( \frac{\log n}{\sqrt{n}} \right) \| B^{(m-1)} x \|_2.
$$

By Cauchy inequality,

$$
\| 1 \cdot 1^T B^{(m-1)} x \|_2 \leq \sqrt{n} \| 1^T B^{(m-1)} x \|_2, \quad \| \sigma \sigma^T B^{(m-1)} x \|_2 \leq \sqrt{n} \| \sigma^T B^{(m-1)} x \|_2.
$$

Therefore,

$$
\| \bar{A} B^{(m-1)} x \|_2 = O(n^{-1/2}) (\| \sigma^T B^{(m-1)} x \|_2 + \| 1^T B^{(m-1)} x \|_2) + O(\log n/\sqrt{n}) \| B^{(m-1)} x \|_2.
$$

Using (9.1) and (9.2), the right hand side in the expression above is upper bounded by

(9.6) \[ O(\alpha^{(m-1)/2} \log n) + O(\| B^{(m-1)} x \|_2 \cdot \log n/\sqrt{n}). \]

Since $B^{(m-1)}$ is a nonnegative matrix, the spectral norm is bounded by the maximum row sum (see Theorem 8.1.22 in [26]), we have that

$$
\| B^{(m-1)} x \|_2 \leq \rho(B^{(m-1)}) \leq \max_{i=1}^n B_{ij}^{(m-1)}.
$$

By (4.1), (4.5) and (4.7), the right hand side above is $O(\alpha^{m-1} \log n)$. Combing (9.6) and noting that $\alpha^{m-1}/\sqrt{n} = o(n^{-1/4})$, it implies

(9.7) \[ \| \bar{A} B^{(m-1)} x \|_2 = O(\alpha^{(m-1)/2} \log n) + O(\alpha^{m-1} \log^2 n/\sqrt{n}) = O(\alpha^{(m-1)/2} \log n). \]

Taking (9.7) into (9.3), we have for any $\varepsilon > 0$, with high probability, $\| B^{(l)} x \|_2 = O(n^\varepsilon \alpha^{l/2} \log^2 n) \leq n^{2\varepsilon} \alpha^{l/2}$ for $n$ sufficiently large. This completes the proof. \[ \square \]
10. Proof of Theorem 5.2

The proof in this section is a generalization of the method in [33] for sparse random graphs. We now prove the case where $\sigma_i = +1$, and the case for $\sigma_i = -1$ can be treated in the same way. Recall the definition of $V_t$ from Definition 4.1. Let $A_t$ be the event that no vertex in $V_t$ is connected by two distinct hyperedges to $V_{t-1}$. Let $B_t$ be the event that there does not exist two vertices in $V_t$ that are contained in a hyperedge $e \subset \binom{V_t}{r}$. We construct the multi-type Poisson hypertree $(T, \rho, \tau)$ in the following way. For a vertex $v \in T$, let $Y_v(r), 0 \leq r \leq d-1$ be the number of hyperedges incident to $v$ with the same spin $\tau$ conditioned on $V_t$. We have

$$Y_v^{(d-1)} \sim \text{Pois} \left( \frac{a}{2d-1} \right), \quad Y_v^{(r)} \sim \text{Pois} \left( \frac{(d-r)b}{2d-1} \right), 0 \leq r \leq d-2.$$

Note that $(T, \rho, \tau)$ can be entirely reconstructed from the label of the root and the sequence $\{Y_v^{(r)}\}$ for $v \in V(T), 0 \leq r \leq d-1$.

We define similar random variables for $(H, i, \sigma)$. For a vertex $v \in V_t$, let $X_v^{(r)}$ be the number of hyperedges incident to $v$, where all the remaining $d-1$ vertices are in $V_{t+1}$ such that $r$ of them have spin $\sigma(v)$. Then we have

$$X_v^{(d-1)} \sim \text{Bin} \left( \binom{|V| - t}{d-1}, \frac{a}{d-1} \right), \quad X_v^{(r)} \sim \text{Bin} \left( \binom{|V| - t}{d-1 - r}, \frac{b}{d-1} \right), 0 \leq r \leq d-2$$

and conditioned on $\mathcal{F}_t$ (recall the definition of $\mathcal{F}_t$ from (8.6)) they are independent. Recall Definition 5.1.

We have the following lemma on the spin-preserving isomorphism. The proof of Lemma 10.1 is given in Appendix A.8.

Lemma 10.1. Let $(H, i, \sigma)_t, (T, \rho, \tau)_t$ be the rooted hypergraph truncated at distance $t$ from $i, \rho$ respectively. If

1. there is a spin-preserving isomorphism $\phi$ such that $(H, i, \sigma)_{t-1} \equiv (T, \rho, \tau)_{t-1}$,
2. for every $v \in V_{t-1}$, $X_v^{(r)} = Y_{\phi(v)}^{(r)}$ for $0 \leq r \leq d-1$,
3. $A_t, B_t$ hold,

then $(H, i, \sigma)_t \equiv (T, \rho, \tau)_t$.

To make our notation simpler, for the rest of this section, we will identify $v$ with $\phi(v)$. Recall the event $\Omega_t(i) = \{S_t(i) \leq C \log(n) \alpha^t\}$ where the constant $C$ is the same one as in Theorem 4.2. Now define a new event

$$(10.1) \quad C_t := \bigcap_{s \leq t} \Omega_s(i).$$

From the proof of Theorem 4.2, for all $t \leq l$, $\mathbb{P}_{H_{\alpha}}(C_t) = 1 - O(n^{-1-\gamma})$ for any $\gamma \in (0, 3/8)$. Note that conditioned on $C_t$, there exists $C' > 0$ such that

$$(10.2) \quad |V_{\leq t}| \leq \sum_{s \leq t} C \log(n) \alpha^s \leq C' \log^2(n) \alpha^t.$$

We now estimate the probability of event $A_t, B_t$ conditioned on $C_t$. The proof is included in Appendix A.9.

Lemma 10.2. For any $t \geq 1$,

$$\mathbb{P}(A_t | C_t) \geq 1 - o(n^{-1/2}), \quad \mathbb{P}(B_t | C_t) \geq 1 - o(n^{-1/2}).$$

Before proving Theorem 5.2, we also need the following bound on the total variation distance between binomial and Poisson random variables, see for example Lemma 4.6 in [33].
Lemma 10.3. Let $m, n$ be integers and $c$ be a positive constant. The following holds:

$$\|\text{Bin} \left( m, \frac{c}{n} \right) - \text{Pois}(c) \|_{TV} = O \left( \frac{1}{n} \sqrt{|m-n|} \right).$$

Proof of Theorem 5.2. Fix $t$ and suppose that $C_t$ holds, and $(T, \rho)_t \equiv (H, i)_t$. Then for each $v \in V_t$, recall

$$X_{d-1}^{(d-1)} \sim \text{Bin} \left( \left\lfloor \frac{|V_{\sigma}^v(t)|}{d-1} \right\rfloor, \frac{a}{n_{d-1}} \right), \quad X_{n_r}^{(r)} \sim \text{Bin} \left( \left\lfloor \frac{|V_{\sigma}^v(t)|}{r} \right\rfloor, \frac{b}{n_{d-1}} \right)$$

and

$$Y_{d-1}^{(d-1)} \sim \text{Pois} \left( \frac{a}{2d-1} \right), \quad Y_{n_r}^{(r)} \sim \text{Pois} \left( \frac{(d-1)b}{2d-1} \right), \quad 0 \leq r \leq d - 2.$$

Recall $|n^\pm - n/2| \leq \sqrt{n} \log n$. We have the following bound for $V_{d-1}^{\pm}$:

$$|V_{d-1}^{\pm}| \geq n^\pm - |V_{\leq 1}| \geq \frac{n}{2} - \sqrt{n} \log(n) - O(\log^2(n)\alpha^2) \geq \frac{n}{2} - 2\sqrt{n} \log(n),$$

$$|V_{d-1}^{\pm}| \leq n^\pm \leq \frac{n}{2} + \sqrt{n} \log(n).$$

Therefore $|V_{d-1}^{\pm} - \frac{n}{2}| \leq 2\sqrt{n} \log(n)$. Then from Lemma 10.3,

$$\|X_{d-1}^{(d-1)} - Y_{d-1}^{(d-1)}\|_{TV} \leq C \frac{\left\lfloor \frac{|V_{\sigma}^v(t)|}{d-1} \right\rfloor - \frac{1}{2}\left\lfloor \frac{n}{d-1} \right\rfloor}{\frac{1}{2}\left\lfloor \frac{n}{d-1} \right\rfloor} = O(n^{-1/2} \log n),$$

$$\|X_{n_r}^{(r)} - Y_{n_r}^{(r)}\|_{TV} = O(n^{-1/2} \log n), \quad 0 \leq r \leq d - 2.$$

We can couple $X_{d-1}^{(d-1)}$ with $Y_{d-1}^{(d-1)}$, $0 \leq r \leq d - 1$ such that $\mathbb{P} \left( X_{d-1}^{(d-1)} \neq Y_{d-1}^{(d-1)} \right) = O(n^{-1/2} \log n)$. Taking a union bound over all $v \in V_t$, and $0 \leq r \leq d - 1$ and recall (10.2), we can find a coupling such that with probability at least

$$1 - O(\log^3(n)\alpha^4n^{-1/2}) \geq 1 - o(n^{-1/4}),$$

$X_{n_r}^{(r)} = Y_{n_r}^{(r)}$ for every $v \in V_t$ and $0 \leq r \leq d - 1$.

Lemma 10.2 implies $A_t, B_t, C_t$ hold simultaneously with probability at least $1 - o(n^{-1/4})$. Altogether we have that assumptions (2),(3) in Lemma 10.1 hold with probability $1 - o(n^{-1/4})$, which can be written as

$$\mathbb{P} \left( (H, i, \sigma)_{t+1} \equiv (T, \rho, \tau)_{t+1}, C_{t+1} \right) \equiv (T, \rho, \tau)_t, C_t \right) \geq 1 - o(n^{-1/4}).$$

Since we can certainly couple $i$ with $\rho$ from our construction, we have $\mathbb{P} \left( (H, i, \sigma)_0 \equiv (T, \rho, \tau)_0, C_0 \right) = 1$. Therefore for large $n$,

$$\mathbb{P} \left( (H, i, \sigma)_t \equiv (T, \rho, \tau)_t \right)$$

$$= \prod_{i=1}^l \mathbb{P} \left( (H, i, \sigma)_t \equiv (T, \rho, \tau)_t, C_t \right) \geq (1 - o(n^{-1/4}))^l \geq 1 - n^{-1/5}.$$

This completes the proof. \qed

11. Proof of Theorem 6.1

The proof of the following Lemma 11.1 follows in a similar way as Lemma 4.4 in [32], and we include it in Appendix A.10.

Lemma 11.1. For $l = c \log(n), c \log(\alpha) < 1/4$, the following hold asymptotically almost surely

\begin{align*}
(11.1) \quad & \| B^{(l)} 1 - \hat{S}_l \|_2 = o(\| B^{(l)} 1 \|_2), \\
(11.2) \quad & \| B^{(l)} \sigma - \hat{D}_l \|_2 = o(\| B^{(l)} \sigma \|_2), \\
(11.3) \quad & \langle B^{(l)} 1, B^{(l)} \sigma \rangle = o \left( \| B^{(l)} 1 \|_2 \cdot \| B^{(l)} \sigma \|_2 \right). 
\end{align*}
The next lemma estimate $\|B^{(i)}x\|_2$ when $x = B^{(i)}\sigma$ and $B^{(i)}1$. The proof of Lemma 11.2 is provided in Appendix A.11.

**Lemma 11.2.** Assume $\beta^2 > \alpha > 1$ and $l = c \log(n)$ with $c \log(\alpha) < 1/8$. Then for some fixed $\gamma > 0$ asymptotically almost surely one has
\begin{align}
\Omega(\alpha^t)\|B^{(1)}\|_2 & \leq \|B^{(1)}B^{(1)}\|_2 \leq O(\alpha^t \log n)\|B^{(1)}\|_2, \\
\Omega(\beta^t)\|B^{(i)}\|_2 & \leq \|B^{(i)}B^{(i)}\|_2 \leq O(n^{-\gamma}\alpha^t)\|B^{(i)}\|_2.
\end{align}

Together with Lemma 11.1 and Lemma 11.2, we are ready to prove Theorem 6.1.

**Proof of Theorem 6.1.** From Theorem 4.6 and Lemma 11.2, the top two eigenvalues of $B^{(i)}$ will be asymptotically in the span of $B^{(1)}$ and $B^{(i)}\sigma$. By the lower bound in (11.4) and the upper bound in (11.5), the largest eigenvalue of $B^{(i)}$ will be $\Theta(\alpha^t)$ up to a logarithmic factor, and the first eigenvector is asymptotically aligned with $B^{(1)}1$.

From (11.1), $B^{(1)}1$ is also asymptotically aligned with $S_1$, therefore our statement for the first eigenvalue and eigenvector holds. Since $B^{(1)}1$ and $B^{(i)}\sigma$ are asymptotically orthogonal from (11.3), together with (11.5), the second eigenvalue of $B^{(i)}$ is $\Omega(\beta^t)$ and the second eigenvector is asymptotically aligned with $B^{(i)}\sigma$. From (11.2), $B^{(i)}\sigma$ is asymptotically aligned with $\hat{D}_i$. So the statement for the second eigenvalue and eigenvector holds. The order of other eigenvalues follows from Theorem 4.6 and the Courant minimax principle (see [26]).
Finally, for large \( n \),
\[
\mathbb{P}_{\mathcal{H}_n}(\{V_{\leq l}(i) \cap V_{\leq l}(j) = \emptyset\}) = \mathbb{P}_{\mathcal{H}_n}(L_l) \geq \mathbb{P}_{\mathcal{H}_n}(V_l(i) \cap V_l(j) = \emptyset | L_{l-1}) \mathbb{P}_{\mathcal{H}_n}(L_{l-1})
\]
\[
\geq \mathbb{P}_{\mathcal{H}_n}(L_0) \prod_{k=0}^{l-1} \mathbb{P}_{\mathcal{H}_n}(V_{k+1}(i) \cap V_{k+1}(j) = \emptyset | L_k) \\
\geq (1 - O(n^{-1/2}))^l \geq 1 - n^{-1/3}.
\]
This completes the proof. \( \square \)

### A.2. Proof of Lemma 4.4.

**Proof.** Consider the exploration process of the neighborhood of a fixed vertex \( i \). Conditioned on \( \mathcal{F}_{k-1} \), there are two ways to create new cycles in \( V_{\geq k-1}(i) \):

1. **Type 1:** a new hyperedge \( e \subseteq V_{\geq k-1}(i) \) containing two vertices in \( V_{k-1}(i) \) may appear, which creates a cycle including two vertices in \( V_{k-1}(i) \).
2. **Type 2:** two vertices in \( V_{k-1}(i) \) may be connected to the same vertex in \( V_{\geq k}(i) \) by two new distinct hyperedges.

Define the event
\[
\Omega_{k-1}(i) := \{ S_{k-1}(i) \leq C \log(n) \alpha^{k-1} \},
\]
where the constant \( C \) is the same one as in Theorem 4.2. From the proof of Theorem 4.2, \( \mathbb{P}_{\mathcal{H}_n}(\Omega_k(i)) = 1 - O(n^{-\gamma}) \) for some \( \gamma \in (0, 3/8) \). Let \( E_k^{(1)}(i) \) be the number of hyperedges of type 1. Conditioned on \( \mathcal{F}_{k-1} \), \( E_k^{(1)}(i) \) is stochastically dominated by \( \text{Bin} \left( \frac{\log(n) \alpha^{k-2}}{2}, \frac{\alpha \beta}{(n - 1)} \right) \). Then for some constant \( C_1 > 0 \),
\[
\mathbb{E}_{\mathcal{H}_n}[E_k^{(1)}(i) | \Omega_{k-1}(i)] \leq C_1 \log^2(n) \alpha^{2k-2}/n \leq C_1 \log^2(n) \alpha^{2l}/n.
\]

By Markov’s inequality,
\[
\mathbb{P}_{\mathcal{H}_n}(\{E_k^{(1)}(i) \geq 1\}) \leq \mathbb{P}_{\mathcal{H}_n}(\{E_k^{(1)}(i) \geq 1\} | \Omega_{k-1}(i)) + \mathbb{P}_{\mathcal{H}_n}(\Omega_{k-1}(i)) \\
\leq \mathbb{E}_{\mathcal{H}_n}[E_k^{(1)}(i) | \Omega_{k-1}(i)] + O(n^{-1-\gamma}) = O(\log^2(n) \alpha^{2l}/n).
\]

Taking the union bound, the probability that there is a type 1 hyperedge in the \( l \)-neighborhood of \( i \) is
\[
\mathbb{P}_{\mathcal{H}_n}\left( \bigcup_{k=1}^{l} \{E_k^{(1)}(i) \geq 1\} \right) \leq \sum_{k=1}^{l} \mathbb{P}_{\mathcal{H}_n}(\{E_k^{(1)}(i) \geq 1\}) = O(\log^3(n) \alpha^{2l}/n).
\]

The number of hyperedge pair \((e_1, e_2)\) of Type 2 is stochastically dominated by
\[
\text{Bin} \left( nS_{k-1}^2 \left( \frac{n}{d - 2} \right)^2, \left( \frac{\alpha \beta}{n - 1} \right)^2 \right),
\]
which conditioned on \( \Omega_{k-1}(i) \) has expectation \( O(\log^2(n) \alpha^{2l}/n) \). By a Markov’s inequality and a union bound, in the same way as the proof for Type 1, we have the probability there is a type 2 hyperedge pair in the \( l \)-neighborhood of \( i \) is \( O(\log^2(n) \alpha^{2l}/n) \). Altogether the probability that there are at least one cycles within the \( l \)-neighborhood of \( i \) is \( O(\log^3(n) \alpha^{2l}/n) \).

Let \( Z_i \) be the random variable such that \( Z_i = 1 \) if \( l \)-neighborhood of \( i \) contains one cycle and \( Z_i = 0 \) otherwise. From the analysis above, we have \( \mathbb{E}[Z_i] = O(\log^3(n) \alpha^{2l}/n) \). By Markov’s inequality,
\[
\mathbb{P}_{\mathcal{H}_n}\left( \sum_{i \in [n]} Z_i \geq \alpha^{2l} \log^4(n) \right) \leq \sum_{i \in [n]} \mathbb{E}[Z_i] = \frac{O(\log^3(n) \alpha^{2l})}{\alpha^{2l} \log^4(n)} = O(\log^{-1}(n)).
\]

Then asymptotically almost surely the number of vertices whose \( l \)-neighborhood contains one cycle at most \( \log^2(n) \alpha^{2l} \). It remains to show \( H \) is \( l \)-tangle free asymptotically almost surely. For a fixed vertex \( i \in [n] \), there are several possible cases where there can be two cycles in \( V_{\leq l}(i) \).
(1) There is one hyperedge of Type 1 or a hyperedge pair of Type 2 which creates more than one cycles. We discuss in the following cases conditioned on the event \( \cap_{i=1}^{l} \Omega_{i}(i) \).
(a) The number of hyperedge of the first type which connects to more than two vertices in \( V_{k-1} \) is stochastically dominated by Bin \( \left( S_{k-1}^{-1} \right) \frac{n}{d-3}, \frac{\alpha \nu b}{(d-1)} \). The expectation is at most \( O(\alpha^{3l} \log^{3}(n)/n^{2}) \).
(b) If the intersection of the hyperedge pair of Type 2 contains 2 vertices in \( V_{k-1} \), it will create two cycles.

The number of such hyperedge pairs is stochastically dominated by Bin \( \left( \frac{n}{2} S_{3}^{-1} \left( \frac{n}{d-3} \right)^{2}, \left( \frac{\alpha \nu b}{(d-1)} \right)^{2} \right) \).

Then by Markov’s inequality and a union bound, asymptotically almost surely, there is no \( \cap \) such that its neighborhood contains Type 1 hyperedges or Type 2 hyperedge pairs which create more than one cycles.

(2) The remaining case is that there is a \( \cap \) where two cycles are created by two Type 1 hyperedges or two Type 2 hyperedge pairs or one Type 1 hyperedge and another hyperedge pairs. By the same argument, under the event \( \cap \), the probability that such event happens is \( O(\log(n) \alpha^{4l}/n^{2}) \). Since \( \alpha^{4l} = o(n) \), by taking a union bound over \( i \in [n] \), we have \( H \) is \( l \)-tangle-free asymptotically almost surely.

A.3. Proof of Lemma 4.5.

Proof. Let \( i \notin B \) whose \( l \)-neighborhood contains no cycles. For any \( k \in [n] \) and any \( m \leq l \), there is a unique self-avoiding walk of length \( m \) from \( i \) to \( k \) if and only if \( d(i, k) = m \), so we have \( B_{ik}^{(m)} = 1_{d(i, k) = m} \). For such \( i \) we have

\[
(B^{(m)}1)_{i} = S_{m}(i), \quad (B^{(m)}\sigma_{i})_{i} = D_{m}(i).
\]

Then (4.5), (4.6) follows from Theorem 4.2. By Lemma 4.4, asymptotically almost surely all vertices in \( \cap \) have only one cycle in \( l \)-neighborhood. For any \( k \in [n] \) with \( B_{ik}^{(m)} \neq 0 \), since the \( l \)-neighborhood of \( i \) contains at most one cycle, there are at most 2 self-avoiding walks of length \( m \) between \( i \) and \( k \). Altogether we know

\[
\sum_{k \in [n]} B_{ik}^{(m)} \leq 2 \sum_{t=0}^{m} S_{t}(i) = O(\alpha^{m} \log n)
\]

asymptotically almost surely. Then (4.7) follows.

A.4. Proof of Lemma 5.3.

Proof. Recall the definitions of \( \alpha, \beta \) from (1.3). From (5.1)-(5.3),

\[
E(W_{t+1}^{+} | G_{t}) = \sum_{r=0}^{d-1} rE(W_{t+1}^{(r)} | G_{t}) = \sum_{r=1}^{d-2} r \left( \frac{b(r-1)}{2^{d-1}} (W_{t}^{+} + W_{t}^{-}) \right) + (d-1) \left( \frac{a}{2^{d-1}} W_{t}^{+} + \frac{b}{2^{d-1}} W_{t}^{-} \right)
\]

\[
= \frac{\alpha + \beta}{2} W_{t}^{+} + \frac{\alpha - \beta}{2} W_{t}^{-} = \frac{\alpha^{t+1}}{2} M_{t} + \frac{\beta^{t+1}}{2} \Delta_{t}.
\]

Similarly, \( E[W_{t+1}^{-} | G_{t}] = \frac{\alpha^{t+1}}{2} M_{t} - \frac{\beta^{t+1}}{2} \Delta_{t} \). Therefore

\[
E[M_{t+1} | G_{t}] = \alpha^{t-1} E[M_{t+1}^{+} + W_{t+1}^{-} | G_{t}] = M_{t},
\]

\[
E[\Delta_{t+1} | G_{t}] = \beta^{t-1} E[W_{t+1}^{+} - W_{t+1}^{-} | G_{t}] = \Delta_{t}.
\]

It follows that \{\( M_{t} \), \( \Delta_{t} \)\} are martingales with respect to \( G_{t} \). From (5.1)-(5.4),

\[
Var(M_{t} | G_{t-1}) = Var(\alpha^{-t}(W_{t}^{+} + W_{t}^{-}) | G_{t-1}) = \alpha^{-2t} Var \left( (d-1) \sum_{r=0}^{d-1} W_{t}^{(r)} | G_{t-1} \right)
\]

\[
= (d-1)^{2} \alpha^{-2t} \frac{\alpha}{d-1}(W_{t}^{+} + W_{t}^{-}) = (d-1)\alpha^{-t} M_{t-1}.
\]

35
Sine $E M_0 = 1$, by conditional variance formula,
$$
\text{Var}(M_t) = \text{Var}(E[M_t|G_{t-1}]) + E\text{Var}(M_t|G_{t-1}) = \text{Var}(M_{t-1}) + (d-1)\alpha^{-t}.
$$
Since $\text{Var}(M_0) = 0$, we have for $t \geq 0$, $\text{Var}(M_t) = (d-1)\frac{1}{\alpha-t}$. So $\{M_t\}$ is uniformly integrable for $\alpha > 1$.

Similarly,
$$
\text{Var}(\Delta_t|G_{t-1}) = \text{Var}(\beta^{-t}(W_t^+-W_t^-)|G_{t-1}) = \beta^{-2t}\sum_{r=0}^{d-1}(2r-d+1)^2\text{Var}(W_t^{(r)}|G_{t-1})
$$
$$
= (\alpha/\beta^2)\beta^{-t}.Var(\Delta_t\log(\sqrt{\frac{d}{\beta}})) =: \kappa(\alpha/\beta^2)\beta^{-t},
$$
where $k := \frac{(d-1)(a-b)2^{d-1}b}{a+2^{d-1}-1}$. And we also have the following recursion:
$$
\text{Var}(\Delta_t) = \text{Var}(E[\Delta_t|G_{t-1}]) + E\text{Var}(\Delta_t|G_{t-1}) = \text{Var}(\Delta_{t-1}) + \kappa\beta^{-2t}\alpha^t.
$$
Since $\text{Var}(\Delta_0) = 0$, we have for $t > 0$,
$$
\text{Var}(\Delta_t) = \kappa \cdot \frac{1 - (\beta^2/\alpha)^t}{\beta^2/\alpha - 1}.
$$
So $\{\Delta_t\}$ is uniformly integrable if $\beta^2 > \alpha$. From the martingale convergence theorem, $E\Delta_\infty = \Delta_0 = 1$, $\text{Var}(\Delta_\infty) = \frac{\kappa}{\beta^2/\alpha - 1}$, and (5.5) holds. This finishes the proof.

A.5. Proof of Lemma 5.4.

Proof. From Theorem 5.2, for each $i \in [n]$, there exists a coupling such that with probability $1 - O(n^{-\epsilon})$ for some positive $\epsilon$, $\beta^{-1}\sigma(i)D_i(i) = \Delta_i$ and we denote this event by $C$. When the coupling fails, by Theorem 4.2, $\beta^{-1}\sigma(i)D_i(i) = O(\log(n))$ with probability $1 - O(n^{-\gamma})$ for some $\gamma > 0$. Recall the event
$$
\Omega_{k-1}(i) := \{S_{k-1}(i) \leq C \log(n)\alpha^{k-1}\}.
$$
We define $\Omega := \bigcap_{i=1}^n \Omega(i)$, $\Omega(i) := \bigcap_{k \leq i} \Omega_k(i)$. We have
$$
E\left(\frac{1}{n} \sum_{i=1}^n \beta^{-2d}D_i^2(i) | \Omega\right) = O(\log^2(n))n^{-\epsilon} + E(\Delta_\infty^21_C | \Omega).
$$
Moreover,
$$
|E(\Delta_\infty^21_C | \Omega) - E(\Delta_\infty^2)| = \frac{|E(\Delta_\infty^21_C - E(\Delta_\infty^21_C | \Omega) - P(\Omega)E(\Delta_\infty^2)|}{P(\Omega)}
$$
$$
\leq \frac{|E(\Delta_\infty^2 - \Delta_\infty^2 | \Omega)|}{P(\Omega)} + \frac{1 - P(\Omega)}{P(\Omega)}E(\Delta_\infty^2) + \frac{|E(\Delta_\infty^21_C | \Omega) - E(\Delta_\infty^21_C | \Omega)|}{P(\Omega)}.
$$
Since we know $P(\Omega \cap C) \to 1$ and (5.5), the first two terms in (A.5) converges to 0. The third term also converges to 0 by dominated convergence theorem. So we have
$$
E\left(\frac{1}{n} \sum_{i=1}^n \beta^{-2d}D_i^2(i) | \Omega\right) \to E(\Delta_\infty^2).
$$
We then estimate the second moment. Note that
$$
E\left(\frac{1}{n} \sum_{i=1}^n \beta^{-2d}D_i^2(i) | \Omega\right)^2 = \frac{1}{n^2}E\left(\sum_{i=1}^n \beta^{-4d}D_i^2(i) | \Omega\right) + \frac{2}{n^2} \sum_{i<j} \beta^{-4d}E(D_i(i)^2D_j(j) | \Omega),
$$
and from Theorem 4.2, the first term is $O(\log^4(n)/n) = o(1)$. Next, we show the second term satisfies
$$
\frac{2}{n^2} \sum_{i<j} \beta^{-4d}E(D_i(i)^2D_j(j) | \Omega) = \frac{2}{n^2} \sum_{i<j} \beta^{-4d} \frac{1}{P(\Omega)}E(1_{\Omega}D_i(i)^2D_j(j)) = o(1).
$$
Since $P(\Omega) = 1 - O(n^{-\gamma})$, it suffices to show
\[
\frac{2}{n^2} \sum_{i < j} \beta^{-4l} \mathbb{E}(1_{\Omega} D_l(i)^2 D_l^2(j)) = o(1).
\]

Consider \( \beta^{-4l} \mathbb{E}(1_{\Omega(i) \cap \Omega(j)} D_l(i)^2 D_l^2(j)) \). From Lemma 4.3, when \( i \neq j \), \( D_l(i), D_l(j) \) are asymptotically independent. On the event that the coupling with independent copies fails (recall the failure probability is \( O(n^{-\gamma}) \)), we bound \( D_l(i)^2 D_l^2(j) \) by \( O(\beta^{4l} \log^4 n) \). When the coupling succeeds,

\[
\beta^{-4l} \mathbb{E}(1_{\Omega(i) \cap \Omega(j)} D_l(i)^2 D_l^2(j)) = \beta^{-4l} \mathbb{E}(1_{\Omega(i)} D_l(i)^2) \mathbb{E}(1_{\Omega(j)} D_l(j)^2).
\]

Then from (5.6),

\[
\frac{2}{n^2} \sum_{i < j} \beta^{-4l} \mathbb{E}(1_{\Omega(i) \cap \Omega(j)} D_l(i)^2 D_l^2(j)) = O \left( \frac{1}{n^2} \sum_{i < j} \beta^{-4l} \mathbb{E}(1_{\Omega(i)} D_l(i)^2) \mathbb{E}(1_{\Omega(j)} D_l(j)^2) + O(n^{-2\gamma} \log^4 n) \right)
\]

(A.8)

\[
= O \left( (\mathbb{E}(\Delta_{\infty}^2))^2 \right) = O(1).
\]

Therefore from (A.6), (A.7), and (A.8),

\[
\mathbb{E} \left( \frac{1}{n} \sum_{i=1}^{n} \beta^{-2l} D_l^2(i) | \Omega \right)^2 = O(1).
\]

With (A.4), by Chebyshev’s inequality, conditioned on \( \Omega \), in probability we have

\[
\lim_{n \to \infty} \frac{1}{n} \sum_{i=1}^{n} \beta^{-2l} D_l^2(i) = \mathbb{E}(\Delta_{\infty}^2).
\]

Since \( \mathbb{P}(\Omega) \to 1 \), (5.6) follows.

We now establish (5.7). Without loss of generality, we discuss the case of + sign. Since \( \tau \) is a continuous point of the distribution of \( \Delta_{\infty} \), for any fixed \( \delta > 0 \), we can find two bounded \( K \)-Lipschitz function \( f, g \) for some constant \( K > 0 \) such that

\[
f(x) \leq (1_{x \geq \tau}) \leq g(x), x \in \mathbb{R}, \quad 0 \leq \mathbb{E}(g(\Delta_{\infty}) - f(\Delta_{\infty})) \leq \delta.
\]

Consider the empirical sum \( \frac{1}{n} \sum_{i \in \mathbb{N}^+} f(x_i^{(n)} \sqrt{n \mathbb{E}(\Delta_{\infty}^2)}) \), we have

\[
\left| \frac{1}{n} \sum_{i \in \mathbb{N}^+} f(x_i^{(n)} \sqrt{n \mathbb{E}(\Delta_{\infty}^2)}) - \frac{1}{n} \sum_{i \in \mathbb{N}^+} f(\beta^{-l} D_l(i)) \right| \\
\leq \frac{K}{n} \sum_{i \in \mathbb{N}^+} |x_i^{(n)} - y_i^{(n)}| \sqrt{n \mathbb{E}(\Delta_{\infty}^2)} + \frac{K}{n} \sum_{i \in \mathbb{N}^+} |y_i^{(n)} \sqrt{n \mathbb{E}(\Delta_{\infty}^2)} - \beta^{-l} D_l(i)|.
\]

The first term converges to 0 by the assumption that \( \|x - y\|_2 \to 0 \) in probability. The second term converges to 0 in probability from (5.6). Moreover, \( \frac{1}{n} \sum_{i \in \mathbb{N}^+} f(\beta^{-l} D_l(i)) \) converges in probability to \( \frac{1}{2} \mathbb{E} f(\Delta_{\infty}) \). So we have

\[
\lim_{n \to \infty} \frac{1}{n} \sum_{i \in \mathbb{N}^+} f(x_i^{(n)} \sqrt{n \mathbb{E}(\Delta_{\infty}^2)}) = \frac{1}{2} \mathbb{E} f(\Delta_{\infty}),
\]

and the same holds for \( g \). If follows that

\[
\lim_{n \to \infty} \left| \frac{1}{n} \sum_{i \in \mathbb{N}^+} \mathbb{1}_{\{x_i^{(n)} \geq \tau / \sqrt{n \mathbb{E}(\Delta_{\infty}^2)}\}} - \frac{1}{2} \mathbb{P}(\Delta_{\infty} \geq \tau) \right| \leq \delta
\]

for any \( \delta > 0 \). Therefore (5.7) holds.
A.6. Proof of Lemma 7.2.

Proof. For any $n \times n$ real matrix $M$, we have $\rho(M)^{2k} \leq \text{tr}[(MM^T)^k]$, therefore

$$E_{\mathcal{H}_n}[\rho(\Gamma^{(l,m)})^{2k}] \leq E_{\mathcal{H}_n}\left[\text{tr}\left(\Gamma^{(l,m)}(\Gamma^{(l,m)})^T\right)^k\right] = \sum_{i_1, \ldots, i_{2k} \in [n]} E_{\mathcal{H}_n}\left[\Gamma_{i_1i_2}(\Gamma^{(l,m)})^{i_1i_2} \cdots \Gamma_{i_{2k-1}i_{2k}}(\Gamma^{(l,m)})^{i_{2k-1}i_{2k}}\right].$$

Recall the definition of $r_{ij}^{(l,m)}$ from (7.2), the sum in (A.9) can be expanded to be the sum over all circuits $w = (w_1, \ldots, w_{2k})$ of length $2kl$ which are obtained by concatenation of $2k$ walks of length $l$, and each $w_i, 1 \leq i \leq 2k$ is a concatenation of two self-avoiding walks of length $l - m$ and $m - 1$. The weight that each hyperedge in the circuit contributes can be either $A_{ij}^{e} - A_{ij}^c$, $A_{ij}^c$ or $A_{ij}^{e}$. For all circuits $w$ in (A.9) with nonzero expected weights, there is an extra constraint that each $w_i$ intersects with some other $w_j$, otherwise the expected weight that $w_i$ contributes to the sum (A.9) will be 0. We want to bound the number of such circuits with nonzero expectation.

Let $v, h$ denote the number of distinct vertices and hyperedges traversed by the circuit. Here we don’t count the hyperedges that are weighted by $A_{ij}^c$. We associate a multigraph $G(w)$ for each $w$ as before, but the hyperedges with weight $A_{ij}^c$ are not included. Since $E_{\mathcal{H}_n}[\Gamma_{ij}^{(l,m)}] = 0$ for any $i, j \in [n]$, if the expected weight of $w$ is nonzero, the corresponding graph $G(w)$ must be connected.

We detail the proof for circuits in Case (1), where

- each hyperedge label in $\{e_i\}_{1 \leq i \leq k}$ appears exactly once on $G(w)$;
- vertices in $e_i \setminus \text{end}(e_i)$ are all distinct for $1 \leq i \leq h$, and they are not vertices with labels in $V(w)$, and the cases from other circuits follow similarly following the proof of Lemma 7.1.

Let $m$ be fixed. For each circuit $w$, there are $4k$ self-avoiding walks, and each $w_i$ is broken into two self-avoiding walks of length $m - 1$ and $l - m$ respectively. We adopt the way of encoding each self-avoiding walk as before, except that we must also include the labels of the endpoint $j$ after the traversal of an edge $e$ with weight from $A_{ij}^c$, which gives us the initial vertex of the self-avoiding walk of length $l - m$ within each $w_i$. These extra labels tell us how to concatenate the two self-avoiding walks of length $m - 1$ and $l - m$ into the walk $w_i$ of length $l$. For each $w_i$, label is encoded by a number from $\{1, \ldots, v\}$. So all possible such labels can be bounded by $v^{2k}$. Then the upper bound on the number of valid triplet sequences with extra labels for fixed $v, h$ is now given by $v^{2k}[(v + 1)^2(l + 1)]^{4k(2 + h - v)}$.

The total number of circuits that have the same triplet sequences with extra labels is at most $n^v(d-2)^{h+2k}$ where $h + 2k$ is the total number of distinct hyperedges we can have in $w$, including the hyperedges with weights from $A_{ij}^c$. Combining the two estimates above, the number of all circuits $w$ with given $v, h$ is upper bounded by $n^v(d-2)^{h+2k}v^{2k}[(v + 1)^2(l + 1)]^{4k(2 + h - v)}$.

We also need to bound the possible range of $v, h$. There are overall $2k(l - 1)$ hyperedges traversed in $w$ (remember we don’t count the edges with weights from $A_{ij}^c$). Out of these, $2k(l - m)$ hyperedges (with multiplicity) with weights coming from $A_{ij}^e - A_{ij}^c$ must be at least doubled for the expectation not to vanish. Then the number of distinct hyperedges in $w$ excluding the hyperedge weighted by some $A_{ij}^c$, satisfies $h \leq k(l - m) + 2k(l - 1) - 2k(l - m) = k(l + m - 2)$.

We have $v \geq \max\{m, l - m + 1\}$ since each self-avoiding walk of length $m - 1$ or $l - m$ has distinct vertices. Moreover, since $G(w)$ is connected, $h \geq v - 1$, so we have $v - 1 \leq h \leq k(l + m - 2)$ and the range of $v$ is then given by $\max\{m, l - m + 1\} \leq v \leq k(l + m - 2) + 1$.

The expected weight that a circuit contributes can be estimated similarly as before. From (7.14), the expected weights from $v - 1$ many hyperedges that corresponds to edges on $T(w)$ is bounded by $\left(\frac{a}{(d-1)(d-1)}\right)^{v-1}$. Similar to (7.10), the expected weights from $h - v + 1 + 2k$ many hyperedges that corresponds to edges on $G(w) \setminus T(w)$ together with hyperedges whose weights are from $A_{ij}^c$ is bounded by $\left(\frac{a}{(d-1)}\right)^{h-v+1+2k}$. Putting all estimates together, for fixed $v, h$, the total contribution to the sum is
bounded by

\[
n^v \left( \frac{n}{d_2 - 2} \right)^{h+2k} v^{2k} [(v + 1)^2(l + 1)]^{4k(2 + h - v)} \left( \frac{\alpha}{(d - 1)(n \alpha)} \right)^{v-1} \left( \frac{a \lor b}{(n \alpha)} \right)^{h-v+1+2k}
\]

\[
= n^v \left( \frac{\alpha}{d_2 - 1} \right)^{v-1} \left( \frac{d - 1}{n_2 - d + 2} \right)^{h+2k} v^{2k} Q(k, l, v, h),
\]

where \(Q(k, l, v, h) := [(v + 1)^2(l + 1)]^{4k(2 + h - v)} (a \lor b)^{h-v+1+2k}\). Let \(S_1\) be the contribution of circuits in Case (1) to the sum in (A.9). Summing over all possible \(v\) and \(h\), we have

\[
(A.10) \quad S_1 \leq \sum_{v = m \lor (l - m + 1)}^{k(l + m - 2) + 1} \sum_{h = v - 1}^{k(l + m - 2) + 1} n^v \left( \frac{\alpha}{d_2 - 1} \right)^{v-1} \left( \frac{d - 1}{n_2 - d + 2} \right)^{h+2k} v^{2k} Q(k, l, v, h).
\]

Taking \(l = O(\log n)\), similar to the discussion in (7.16), the leading term in (A.10) is given by the term with \(h = v - 1\). So for any \(1 \leq m \leq l\), and sufficiently large \(n\), there are constants \(C_1, C_2 > 0\) such that

\[
S_1 \leq 2 \sum_{v = m \lor (l - m + 1)}^{k(l + m - 2) + 1} n^1 \alpha^{v-1} [(v + 1)^5(l + 1)^2(d - 1)(a \lor b)]^{2k}
\]

\[
\leq C_1 \log^{14k}(n) \cdot n^1 \alpha^{v-1} \sum_{v = m \lor (l - m + 1)}^{k(l + m - 2) + 1} \alpha^{v-1} \leq C_2 \log^{14k}(n) \cdot n^1 \alpha^{k(l+m-2)}.
\]

For circuits not in Case (1), similar to the proof of Lemma 7.1, their total contribution is bounded by \(C_2' n^{1-2k} \alpha^{k(l+m-2)} \log^{14k}(n)\) for a constant \(C_2' > 0\). This completes the proof of Lemma 7.2. \(\square\)

A.7. Proof of Lemma 9.1.

**Proof.** Let \(B\) be the set of vertices such that their \(l\)-neighborhood contains a cycle. Let \(x\) be a normed vector such that \(x^T B^{1(l)} = 0\). We then have

\[
1^T B^{m-1} x = \sum_{i \in [n]} x_i (B^{m-1}1)_i = \sum_{i \in B} x_i S_{m-1}(i) + \sum_{i \in B} x_i (B^{m-1}1)_i
\]

\[
= \sum_{i \in [n]} x_i (\alpha^{m-1-l}(B^{l}1)_i + O(\alpha^{m-1} \log n))
\]

\[
- \sum_{i \in B} x_i (\alpha^{m-1-l}(B^{l}1)_i + O(\alpha^{m-1} \log n)) + \sum_{i \in B} x_i (B^{m-1}1)_i.
\]

Since we have \(1^T B^{l} x = 0\), the first term in (A.11) satisfies

\[
\left| \sum_{i \in [n]} x_i (\alpha^{m-1-l}(B^{l}1)_i + O(\alpha^{m-1} \log n)) \right| = \sum_{i \in [n]} x_i O(\alpha^{m-1} \log n) = O(\sqrt{n} \alpha^{m-1} \log n),
\]

where the last inequality above is from Cauchy inequality. From Lemma 4.4, \(|B| = O(\alpha^{2l} \log^4 n)\). For the second term in (A.11), recall from (4.7), for \(m \leq l\), \(|(B^{m}1)_i| = O(\alpha^m \log n)\), then by Cauchy inequality

\[
\left| \sum_{i \in B} x_i (\alpha^{m-1-l}(B^{l}1)_i + O(\alpha^{m-1} \log n)) \right| \leq |B| O(\alpha^{m-1} \log n) = O(\alpha^{l+m-1} \log^3 n).
\]

Similarly, the third term satisfies

\[
\left| \sum_{i \in B} x_i (B^{m-1}1)_i \right| = O(\alpha^{l+m-1} \log^3 n).
\]
Note that $\alpha^{l+m-1} = o(n^{1/2})$, altogether we have
\begin{equation}
(\ref{a.12})\quad |1^T B^{(m-1)} x| = O(\sqrt{n} \frac{\alpha^{m-1}}{\sqrt{2}} \log n + \alpha^{l+m-1} \log^3 n) = O(\sqrt{n} \frac{\alpha^{m-1}}{\sqrt{2}} \log n).
\end{equation}

(9.1) then follows. Using the property $x^T B^{(l)} \sigma = 0$ instead of $x^T B^{(l)} 1 = 0$ and following the same argument, (9.2) holds.

\section*{A.8. Proof of Lemma 10.1.}

\textbf{Proof.} Conditioned on $(H, i, \sigma), t-1 \equiv (T, \rho, \tau), t-1$, if $A_t$ holds, it implies that hyperedges generated from vertices in $V_{t-1}$ do not overlap (except for the parent vertices in $V_{t-1}$). If $B_t$ holds, vertices in $V_t$ that are in different hyperedges generated from $H_{t-1}$ do not connect to each other. If both $A_t, B_t$ holds, $(H, i, \sigma), t$ is still a hypertree. Since $X^{(r)} = Y^{(r)}$ for $v \in V_{t-1}$, we can extend the hypergraph isomorphism $\phi$ by mapping the children of $v \in V_t$ to the corresponding vertices in the $t$-th generation of children of $\rho$ in $T$, which keeps the hypertree structure and the spin of each vertex.

\section*{A.9. Proof of Lemma 10.2.}

\textbf{Proof.} First we fix $u, v \in V_t$. For any $w \in V_{\tilde{t}+1}$, the probability that $(u, w), (v, w)$ are both connected is $O(n^{-2})$. We know $|V_{\tilde{t}+1}| \leq n$ and $|V_{\tilde{t}+1}| = O(\log^2 (n) o')$ conditioned on $C_t$. Since $\alpha^{2l} \leq \alpha^{2l} = o(n^{1/2})$, taking a union bound over all $u, v, w$, we have
\begin{equation}
(\ref{a.13})\quad \mathbb{P}(A_t | C_t) \geq 1 - O(\log^4 (n) \alpha^{2l} n^{-1}) = 1 - o(n^{-1/2}).
\end{equation}

For the second claim, the probability of having an edge between $u, v \in V_t$ is $O(n^{-1})$. Taking a union bound over all pairs of $u, v \in V_t$ implies
\begin{equation}
(\ref{a.14})\quad \mathbb{P}(B_t | C_t) \geq 1 - O(\log^4 (n) \alpha^{2l} n^{-1}) = 1 - o(n^{-1/2}).
\end{equation}

\section*{A.10. Proof of Lemma 11.1.}

\textbf{Proof.} In (11.1), the coordinates of two vectors on the left hand side agree at $i$ if the $l$-neighborhood of $l$ contains no cycle. Recall $B$ is the set of vertices whose $l$-neighborhood contains a cycle, from Lemma 4.4, and (4.7), we have asymptotically almost surely,
\begin{equation}
(\ref{a.15})\quad \|B^{(l)} 1 - S_i\|_2 \leq \sqrt{|B|} O(\log (n) \alpha^l) = O(\log^3 (n) \alpha^{2l}) = o(\sqrt{n}).
\end{equation}

From (5.6) we have
\begin{equation}
(\ref{a.16})\quad \|D_t\|_2 = \Theta(\sqrt{n} \beta^l)
\end{equation}
asymptotically almost surely, and $\|B^{(l)} 1\|_2 \geq \|D_t\|_2$, therefore (11.1) follows. Similar to (A.15), we have
\begin{equation}
(\ref{a.17})\quad \|B^{(l)} \sigma - D_t\|_2 = o(\sqrt{n}) \quad \|B^{(l)} \sigma\|_2 = \|D_t\|_2 + o(\sqrt{n}) = \Theta(\sqrt{n} \beta^l).
\end{equation}

Then (11.2) follows. It remains to show (11.3). Using the same argument as in Theorem 5.4, we have the following convergence in probability
\begin{equation}
(\ref{a.18})\quad \lim_{n \to \infty} \frac{1}{n} \sum_{i \in [n]} \alpha^{-2l} S_i^2 (i) = \mathbb{E} M_\infty^2,
\end{equation}
where $M_\infty$ is the limit of the martingale $M_t$. Similarly, the following convergences in probability hold
\begin{equation*}
\lim_{n \to \infty} \frac{1}{n} \sum_{i \in [n]} \alpha^{-l} \beta^{-l} S_i (i) D_i (i) = \alpha^{-l} \beta^{-l} \lim_{n \to \infty} \frac{1}{n} \sum_{i \in \mathcal{N}^+} \alpha^{-l} \beta^{-l} S_i (i) D_i (i) + \lim_{n \to \infty} \frac{1}{n} \sum_{i \in \mathcal{N}^-} \alpha^{-l} \beta^{-l} S_i (i) D_i (i)
\end{equation*}
\begin{equation*}
= \frac{1}{2} \mathbb{E} M_\infty D_\infty - \frac{1}{2} \mathbb{E} M_\infty D_\infty = 0.
\end{equation*}

Thus $(\tilde{S}_t, \tilde{D}_t) = o(\alpha \beta^l)$ asymptotically almost surely. From (11.1) we have
\begin{equation}
(\ref{a.19})\quad \|\tilde{S}_t\|_2 = \Theta(\sqrt{n} \alpha^l),
\end{equation}
therefore together with (A.16), we have $\|\tilde{S}_t\|_2 \cdot \|D_t\|_2 = \Theta(n \alpha^{2l})$. With (11.1) and (11.2), (11.3) holds. \qed
A.11. Proof of Lemma 11.2.

Proof. For the lower bound in (11.4), note that $B^{(l)}$ is symmetric, we have

\[(A.20)\quad \|B^{(l)}\mathbf{1}\|_2^2 = \langle B^{(l)}\mathbf{1}, B^{(l)}\mathbf{1} \rangle = \langle \mathbf{1}, B^{(l)}B^{(l)}\mathbf{1} \rangle \leq \|\mathbf{1}\|_2\|B^{(l)}B^{(l)}\mathbf{1}\|_2.
\]

Therefore from (A.19) and (11.1),

\[(A.21)\quad \|B^{(l)}B^{(l)}\mathbf{1}\|_2 \geq \frac{\|B^{(l)}\mathbf{1}\|_2^2}{\|\mathbf{1}\|_2} = \Theta(\alpha^l)\|B^{(l)}\mathbf{1}\|_2.
\]

For the upper bound in (11.4), from (4.1) and (4.7), the maximum row sum of $B^{(l)}$ is $O(\alpha^l \log n)$. Since $B^{(l)}$ is nonnegative, the spectral norm $\rho(B^{(l)})$ is bounded by the maximal row sum, hence (11.4) holds. The lower bound in (11.5) can be proved similarly as in (11.4), from the inequality $\|B^{(l)}\sigma\|_2^2 \leq \|\sigma\|_2\|B^{(l)}B^{(l)}\sigma\|_2$ together with (A.16) and (11.2). Recall $\mathcal{B}$ is the set of vertices whose $l$-neighborhood contains cycles. Let $\overline{\mathcal{B}} = [n] \setminus \mathcal{B}$. Since

\[
\left( B^{(l)}(B^{(l)}\sigma) \right)_i = \sum_{j \in [n]} B^{(l)}_{ij}(B^{(l)}\sigma)_j,
\]

we can decompose the vector $B^{(l)}B^{(l)}\sigma$ as a sum of three vectors $z + z' + z''$, where

\[
\begin{align*}
z_i &= \mathbf{1}_\mathcal{B}(i) \sum_{j : d(i,j) = l} D_l(j) \mathbf{1}_\mathcal{B}(j),
\quad z'_i &= \mathbf{1}_\mathcal{B}(i) \sum_{j : d(i,j) = l} O(\alpha^l \log n) \mathbf{1}_\mathcal{B}(j),
\quad z''_i &= \mathbf{1}_\mathcal{B}(i) O(\alpha^{2l} \log^2 n).
\end{align*}
\]

The decomposition above depends on whether $i,j \in \mathcal{B}$ and the estimation follows from (4.7). From Lemma 4.4, $\mathcal{B} = O(\alpha^{2l} \log^4(n))$ asymptotically almost surely, so one has

\[
\|z'\|_2^2 = \sum_{i=1}^n (z'_i)^2 = \sum_{i \in \mathcal{B}} \sum_{j : d(i,j) = l} O(\alpha^{2l} \log^2 n) \mathbf{1}_\mathcal{B}(j) \mathbf{1}_\mathcal{B}(j') = \sum_{i,j \in \mathcal{B}} O(\alpha^{2l} \log^2 n) = \sum_{j,j' \in \mathcal{B}} O(\alpha^{3l} \log^3 n) = O(\alpha^{7l} \log^{11} n),
\]

which implies $\|z'\|_2 = O(\alpha^{7l/2} \log^{11/2} n)$. And similarly $\|z''\|_2 = O(\alpha^{3l} \log^2 n)$. We know from (A.17), $\|B^{(l)}\sigma\|_2 = \Theta(\beta^l \sqrt{n})$, and since $c \log \alpha < 1/8$, we have $\alpha^{5l/2} = n^{-\gamma} \sqrt{n}$ for some $\gamma > 0$, therefore

\[(A.22)\quad \|z' + z''\|_2 = O(\alpha^{7l/2} \log^{11/2} n) = o(\alpha^{5l/2} \beta^2) = O(n^{-\gamma} \beta^l \|B^{(l)}\sigma\|_2).
\]

It remains to upper bound $\|z\|_2$. Assume the $2l$-neighborhood of $i$ is cycle-free, then the $i$-th entry of $B^{(l)}B^{(l)}\sigma$, denoted by $X_i$, can be written as

\[
X_i := (B^{(l)}B^{(l)}\sigma)_i = \sum_{k=1}^n B_{ik}^{(l)}(B^{(l)}\sigma)_k = \sum_{k=1}^n \mathbf{1}_{d(i,k)=l} \sum_{j=1}^n \mathbf{1}_{d(j,k)=l} \sigma_j
\]

\[(A.23)\quad = \sum_{h=0}^l \sum_{j : d(i,j) = 2h} \sigma_j | \{ k : d(i,k) = d(j,k) = l \}|.
\]

We control the magnitude of $X_i$ in the corresponding hypertree growth process. Since $2l = 2c \log n$ and $2c \log(\alpha) < 1/4$, the coupling result in Theorem 5.2 can apply. Let $\mathcal{C}_i$ be the event that coupling between $2l$-neighborhood of $i$ with the Poisson Galton-Watson hypertree has succeeded and $n^{-\varepsilon}$ be the failure probability of the coupling. When the coupling succeed, $z_i = X_i$, therefore

\[
\mathbb{E}(\|z\|_2^2 \mid \Omega) = \sum_{i \in [n]} n^{-\varepsilon} O(\alpha^{2l} \beta^2 \log^2 n) + \sum_{i \in [n]} \mathbb{E}(X_i^2 \mathbf{1}_{\mathcal{C}_i} \mid \Omega)
\]

\[= n^{1-\varepsilon} O(\alpha^{2l} \beta^2 \log^2 n) + \sum_{i \in [n]} \mathbb{E}(X_i^2 \mathbf{1}_{\mathcal{C}_i} \mid \Omega).
\]

(A.24)
For any $i, j \in [n], t \in [l]$, define $D_{i,j}^{(t)} := \{k : d(i, k) = d(j, k) = t\}$. From (A.23), we have

(A.25) \[ X_t^2 = \sum_{h,h'=0}^{l} \sum_{j, i} \sum_{j': d(i,j') = 2h'} \sigma_j \sigma_{j'} D_{i,j}^{(t)} D_{i,j'}^{(t)}. \]

We further classify the pair $j, j'$ in (A.25) according to their distance. Let $d(j, j') = 2(h + h' - \tau)$ for $\tau = 0, \ldots, 2(h \land h')$. This yields

\[ X_t^2 = \sum_{h,h'=0}^{l} \sum_{j, i} \sum_{j': d(i,j') = 2h'} \sum_{\tau = 0}^{2(h+h')} 1_{d(j,j') = 2(h+h'-\tau)} \sigma_j \sigma_{j'} D_{i,j}^{(t)} D_{i,j'}^{(t)}. \]

Conditioned on $\Omega$ and $C_i$, similar to the analysis in Appendix H in [32], we have the following holds

(A.26) \[ |\{k : d(i, k) = d(j, k) = l\}| = O(\alpha^{l-h} \log n), \]

(A.27) \[ |\{k' : d(i, k') = d(j', k') = l\}| = O(\alpha^{l-h'} \log n), \]

(A.28) \[ |\{j : d(i, j) = 2h\}| = O(\alpha^{2h} \log n), \]

(A.29) \[ |\{j' : d(i, j') = 2h', d(j, j') = 2(h + h' - \tau)\}| = O(\alpha^{2h'-\tau} \log n). \]

We claim that

(A.30) \[ E[\sigma_j \sigma_{j'} | C_i] \leq \left( \frac{\beta}{\alpha} \right)^{d(j,j')-1}, \]

and prove (A.30) in Cases (a)-(d).

(a) Assume $j$ is the parent of $j'$ in the hyptree growth process. Then $d(j, j') = 1$. Let $\mathcal{T}_r$ be the event that the hyperedge containing $j'$ is of type $r$. Given $\mathcal{T}_r$, by our construction of the hyptree process, the spin of $j'$ is assigned to be $\sigma_j$ with probability $\frac{\alpha}{\alpha + \beta}$ and $-\sigma_j$ with probability $\frac{\beta}{\alpha + \beta}$, so we have

\[ E[\sigma_j \sigma_{j'} | C_i] = \frac{1}{\alpha + \beta} \left( \frac{\alpha}{\alpha + \beta} \right)^{d(j,j')-1}. \]

Recall $P[\mathcal{T}_d-1 | C_i] = \frac{(d-1)a}{\alpha^{2d+1}}$ and $P[\mathcal{T}_r | C_i] = \frac{(d-1)\alpha^{2d-1}}{\alpha^{2d+1}}$ for $0 \leq r \leq d - 2$. A simple calculation implies $E[\sigma_j \sigma_{j'} | C_i] = \frac{\beta}{\alpha} \leq 1$.

(b) Suppose $d(j, j') = t$ and there is a sequence of vertices $j, j_1, \ldots, j_{t-1}, j'$ such that $j_1$ is a child of $j$, $j_i$ is a child of $j_{i-1}$ for $1 \leq i \leq t$, and $j'$ is a child of $j_{t-1}$. We show by induction that for $t \geq 1$, $E[\sigma_j \sigma_{j'} | C_i] = \left( \frac{\beta}{\alpha} \right)^{d(j,j')-1}$. When $t = 1$ this has been approved in part (a). Assume it is true for all $j, j'$ with distance $\leq t - 1$. Then when $d(j, j') = t$, we have

\[ E[\sigma_j \sigma_{j'} | C_i] = E[\sigma_j \sigma_{j'} | \sigma_{j_1} = \sigma_j, C_i] P(\sigma_{j_1} = \sigma_j | C_i) + E[\sigma_j \sigma_{j'} | \sigma_{j_1} = -\sigma_j, C_i] P(\sigma_{j_1} = -\sigma_j | C_i) \]

\[ = \left( \frac{\beta}{\alpha} \right)^{d(j,j')-1} \left( \frac{\alpha}{\alpha + \beta} \right) - \left( \frac{\beta}{\alpha} \right)^{d(j,j')-1} \left( \frac{\beta}{\alpha} \right) \]

\[ = \left( \frac{\beta}{\alpha} \right)^{d(j,j')-1} \left( \alpha \right)^{d(j,j')-1} = \left( \frac{\beta}{\alpha} \right)^{d(j,j')-1}. \]

Therefore $E[\sigma_j \sigma_{j'} | C_i] \leq \left( \frac{\beta}{\alpha} \right)^{d(j,j')-1}$ and $\sigma_j \sigma_{j'}$ is independent. This completes the proof for part (b).

(c) Suppose $j, j'$ are not in the same hyperedge and there exists a vertex $k$ such that $j, k$ satisfies the assumption in Case (b) with $d(j, k) = t_1$, and $j', k$ satisfy the assumption in Case (b) with $d(j', k) = t_2$. Conditioned on $\sigma_k$, we know $\sigma_j$ and $\sigma_{j'}$ are independent. Then we have

\[ E[\sigma_j \sigma_{j'} | C_i] = E[\sigma_j \sigma_{j'} | \sigma_k, C_i] \leq E \left[ E[\sigma_j \sigma_k | \sigma_k, C_i] \cdot E[\sigma_j \sigma_{j'} | \sigma_k, C_i] | C_i \right] \]

\[ = \left( \frac{\beta}{\alpha} \right)^{t_1+t_2} \left( \frac{\beta}{\alpha} \right)^{d(j,j')-1}, \]

where the last line follows from the triangle inequality $d(j, k) + d(j', k) \geq d(j, j')$ and the condition $\beta < \alpha$. 

42
Combining Cases (a)-(d), (A.30) holds. From (A.30) and (A.26)-(A.29), we have

\[ \mathbb{E}[X_t^j 1_{\Omega} \mid C_i] \leq \sum_{h, h' = 0}^{2(h + h')} \sum_{\tau = 0}^{2(h + h')} \sum_{j : d(i,j) = 2h} \sum_{j' : d(i,j') = 2h'} 1_{d(j,j') = 2(h + h' - \tau)} \mathbb{E}[\sigma_j \sigma_{j'} \mid C_i] R_{i,j} R_{i,j'} \]

Then by Chebyshev's inequality, asymptotically almost surely,

\[ (\beta^2 / \alpha) \log n \left( \frac{\beta}{\alpha} \right)^{2(h + h' - \tau) - 1} \cdot O\left( \alpha^{2l - h - h' \log^2 n} \right) \]

\[ \leq \sum_{h, h' = 0}^{2(h + h')} \sum_{\tau = 0}^{2(h + h')} O\left( \alpha^{2l + h + h' - \tau} \log^4 n \left( \frac{\beta}{\alpha} \right)^{2(h + h' - \tau) - 1} \right) \]

\[ = \sum_{h, h' = 0}^{2(h + h')} \sum_{\tau = 0}^{2(h + h')} O\left( \alpha^{2l \log^4 n} \right) \cdot (\beta^2 / \alpha)^{h + h' - \tau} = O(\beta^4 \log^4 n). \]

From (A.24) and (A.31), we have for some \( \epsilon > 0, \)

\[ \mathbb{E}[\|z\|^2 \mid \Omega] = n^{1-\epsilon}O(\alpha^{2l} \beta^2 \log^2 n) + O(n^l \beta^2 \log^2 n). \]

Then by Chebyshev's inequality, asymptotically almost surely,

\[ \|z\|^2 = O(n^{1-\epsilon/2} \alpha^l \beta^2 \log^2 n) + O(n^{1-\epsilon/2} \alpha^l \beta^2 \log^2 n) = (\sqrt{n} \beta^l \log^2 n) \cdot O(\beta^l \alpha^l \log^2 n). \]

Recall \( l = c \log n. \) We have \( \beta^l = n^{c \log \beta}, \alpha^l = n^{c \log \alpha}. \) So \( \beta^l = n^{-\epsilon'} \alpha^l \) for some constant \( \epsilon' > 0. \) Since from (A.17), \( \|B^{(l)} \sigma\|^2 = \Theta(\sqrt{n} \beta^l), \) we have

\[ \|z\|^2 = O(n^{-\gamma''} \alpha^l \|B^{(l)} \sigma\|^2) \]

for some constant \( \gamma'' > 0. \) Combining (A.22) with (A.32), it implies for some constant \( \gamma > 0, \)

\[ \|B^{(l)} B^{(l)} \sigma\|^2 = \|z + z' + z''\|^2 = O(n^{-\gamma} \alpha^l \|B^{(l)} \sigma\|^2). \]

Then the upper bound on \( \|B^{(l)} B^{(l)} \sigma\|^2 \) in (11.5) holds. \( \square \)
