Semi-Implicit Hybrid Gradient Methods
with Application to Adversarial Robustness

Abstract

Adversarial examples, crafted by adding imperceptible perturbations to natural inputs, can easily fool deep neural networks (DNNs). One of the most successful methods for training adversarially robust DNNs is solving a nonconvex-nonconcave minimax problem with an adversarial training (AT) algorithm. However, among the many AT algorithms, only Dynamic AT (DAT) and You Only Propagate Once (YOPO) guarantee convergence to a stationary point. In this work, we generalize the stochastic primal-dual hybrid gradient algorithm to develop semi-implicit hybrid gradient methods (SI-HGs) for finding stationary points of nonconvex-nonconcave minimax problems. SI-HGs have the convergence rate $O(1/K)$, which improves upon the rate $O(1/K^{1/2})$ of DAT and YOPO. We devise a practical variant of SI-HGs, and show that it outperforms other AT algorithms in terms of convergence speed and robustness.

1 INTRODUCTION

Adversarial examples, crafted by adding imperceptible adversarial perturbations to natural inputs, can easily fool deep neural networks (DNNs) (Goodfellow et al., 2015). One of the most successful methods for learning adversarially robust DNNs is adversarial training (AT) (Athalye et al., 2018). Given a dataset $\{(x_i, y_i)\}_{i=1}^n$ comprised of $n$ input-label pairs or batches, a vector of perturbations $\delta = (\delta_1, \ldots, \delta_n)$, perturbation radius $\epsilon > 0$, DNN parameters $w$, and a loss function $\ell$, AT solves the nonconvex-nonconcave minimax problem

$$\min_w \max_\delta \frac{1}{n} \sum_{i=1}^n \ell(x_i + \delta_i, y_i, w). \quad (1)$$

However, among the large number of AT algorithms (Silva & Najafirad, 2020), many do not have theoretical convergence guarantees. Some such algorithms even exhibit a failure mode called catastrophic overfitting, where the DNN accuracy on adversarial examples generated by multiple steps of projected gradient ascent (PGD) drops to a low value in the middle of training (Andriushchenko & Flammarion, 2020).

To the best of our knowledge, there are only two AT algorithms guaranteed to converge to a stationary point of (1): Dynamic AT (DAT) (Wang et al., 2019) and You Only Propagate Once (YOPO) (Zhang et al., 2019a; Seidman et al., 2020). Under certain assumptions on the loss function and stochastic gradients, DAT and YOPO decrease the squared saddle subdifferential norm with rate $O(1/K^{1/2})$ up to an additive constant.

In this work, we take a step towards AT algorithms with better convergence guarantees. To this end, we consider minimax optimization problems of the form

$$\min_w \max_\delta f(w) + \phi(w, \delta) - g(\delta) \quad (2)$$

where

$$\phi(w, \delta) = \sum_{i=1}^n \phi_i(w, \delta_i), \quad g(\delta) = \sum_{i=1}^n g_i(\delta_i) \quad (3)$$

and $w \in \mathbb{R}^n$, $\delta = (\delta_1, \ldots, \delta_n) \in \mathbb{R}^{d_1} \times \cdots \times \mathbb{R}^{d_n}$, $f, g_i$ are convex, and $\phi$ is nonconvex-nonconcave. The AT problem (1) is a special case of this template (c.f. Equation (5)). We propose two semi-implicit hybrid gradient methods (SI-HGs) which solve (2) by alternating between a hybrid gradient descent step on $w$ and an implicit ascent step on $\delta$. The first SI-HG is stochastic SI-HG (SSI-HG), which generalizes stochastic primal-dual hybrid gradient (SPDHG)

Semi-Implicit Hybrid Gradient Methods with Application to Adversarial Robustness

Table 1: Convergence rates w.r.t. squared saddle subdifferential norm for AT algorithms. “—” means N/A. “DT” means deterministic, “S” means stochastic, and “DS” means doubly-stochastic. K is the number of iterations. We omit additive constants for the convergence rates. For SSI-HG, smoothness of \( \ell(\cdot, y_i, \cdot) \) is actually more than what we need to prove the \( O(1/K) \) rate (c.f. Assumption 1 (b) and Theorem 1). Yet, we have written the stronger assumption in this table since we use the smoothness of \( \ell(\cdot, y_i, \cdot) \) in the process of interpreting SSI-HG as MGDA (see Section 4).

| AT Algorithm   | Algorithm Type | Assumption                      | Setting | Convergence      |
|----------------|----------------|---------------------------------|---------|------------------|
| FGSM AT GDA    |                |                                 | DS      | —                |
| PGD AT MGDA    | \( \ell \) continuously diff. in \( w \) | DT     | Global Convergence |
| DAT MGDA       | \( \ell(\cdot, y_i, \cdot, \cdot) \) smooth | DS     | \( O(1/K^{1/2}) \) |
| SSI-HG MGDA    | \( \ell(\cdot, y_i, \cdot, \cdot) \) smooth | S      | \( O(1/K) \)     |
|                | Weak MVI has solution |                   |         |                  |

(Chambolle et al., 2018). The second SI-HG is deterministic SI-HG (DSI-HG), which is the \( n = 1 \) version of SSI-HG.

SI-HGs decrease the squared saddle subdifferential norm with rate \( O(1/K) \) under the weak Minty variational inequality (MVI) condition (Diakonikolas & Daskalakis, 2021). This improves upon the aforementioned \( O(1/K^{1/2}) \) convergence rate of DAT and YOPO. We also prove that SI-HGs achieve a linear rate under the strong MVI condition (Zhou et al., 2017; Song et al., 2020). Our work is a solid step towards AT algorithms with better convergence properties. A variety of experiments substantiate this claim.

We have the following key contributions.

- **SSI-HG.** We propose SSI-HG, which generalizes SPDHG to the nonconvex-nonconcave minimax optimization setting. We show that SSI-HG can be interpreted as a stochastic multi-step gradient descent ascent method (MGDA). Under the weak MVI assumption, we prove that SSI-HG decreases the squared saddle subdifferential norm with rate \( O(1/K) \). We also prove linear convergence under the strong MVI assumption. Our work improves upon the convergence rates for other AT algorithms (Table 1).

- **DSI-HG.** When \( n = 1 \), SSI-HG becomes DSI-HG. DSI-HG inherits all the convergence results for SSI-HG. Hence, if we interpret DSI-HG as MGDA, our work improves upon previous convergence results for MGDA in the nonconvex-nonconcave setting (Table 2).

- **Application of SI-HGs to AT.** We extend the theoretical development behind SI-HGs to the AT setting. Specifically, we develop a minibatch version of SI-HG (MSI-HG). We also propose a heuristic for solving the implicit step in the AT setting. In experiments, we demonstrate MSI-HG indeed converges faster and achieves better robustness than other popular AT methods on multiple datasets.

2 RELATED WORK

Stochastic Primal-Dual Coordinate Methods (SPDCMs). When \( \phi \) is bilinear, the template (2) encompasses problems such as total variation regularized imaging (Chambolle et al., 2018) and regularized empirical risk minimization (Shalev-Shwartz & Zhang, 2013). SPDCMs are often used to solve such problems (Chambolle et al., 2018; Fercoq & Bianchi, 2019; Latafat et al., 2019; Alacaoglu et al., 2020). Due to stochastic coordinate updates in the variable \( \delta \), these methods have lower per-iteration costs than deterministic primal-dual hybrid gradient methods (Chambolle & Pock, 2011; Condat, 2013; Vu, 2013). SSI-HG is inspired by a SPDCM called SPDHG, and it generalizes update both \( w \) and \( \delta \) as being deterministic, methods which use full gradients to update \( w \) and stochastic gradients to update \( \delta \) as being stochastic, and methods which use stochastic gradients to update both \( w \) and \( \delta \) as being doubly-stochastic.
Table 2: Convergence rates for MGDA for \( \phi \) with \( n = 1 \) and nonconvex-nonconcave \( \phi \). “—” means no additional assumptions. Here, \( K \) is the number of iterations. For MGDA, one iteration consists of one \( x \) update and multiple \( y \) updates. The optimality metric for the first and third rows is the squared saddle subdifferential norm whereas the optimality metric for the second row is the squared gradient norm of the Moreau envelope of \( \max_\delta \phi(\cdot, \delta) \).

| \( f(w) \) | \( \phi(w, \delta) \) | \( g(\delta) \) | Assumption | Convergence Rate |
|---|---|---|---|---|
| Indicator function of a convex compact set | Smooth \( -\phi(w, \cdot) \) is \( \mu \)-PL | 0 | — | \( O(1/K) \) [Nouiehed et al. 2019] |
| 0 | Lipschitz and smooth | 0 | — | \( O(1/K^{1/2}) \) [Jin et al. 2020] |

Convex Smooth Convex Weak MVI has solution \( O(1/K) \) (Ours)

SPDHG to the setting where the coupling function \( \phi \) is nonconvex-nonconcave.

**MGDA.** MGDA [Nouiehed et al. 2019; Thekumparampil et al. 2019; Barazandeh & Razaviyayn 2020; Jin et al. 2020] alternates between one gradient descent step for \( x \) and multiple gradient ascent steps for \( y \) to solve minimax problems. There are two convergence rates for MGDA in the nonconvex-nonconcave setting. Nouiehed et al. [2019] proves the rate \( O(1/K) \) with respect to the squared saddle subdifferential norm assuming \( \phi \) is smooth, \( -\phi(w, \cdot) \) is \( \mu \)-Polyak-Lojasiewicz (\( \mu \)-PL), \( f \) is an indicator function of some convex compact set, and \( g \equiv 0 \). Jin et al. [2020] proves the rate \( O(1/K^{1/2}) \) with respect to the squared gradient norm of the Moreau envelope of \( \max_\delta \phi(\cdot, \delta) \) assuming \( f \equiv g \equiv 0 \) and \( \phi \) is Lipschitz and smooth. See Section 4 of the work by Jin et al. [2020] for an explanation on the relation between a function and its Moreau envelope. SI-HGs can be interpreted as variants of MGDA, and our work improves upon previous convergence results for MGDA in the nonconvex-nonconcave setting (Table 2).

**Convergence Guarantees for AT Methods.** PGD AT [Madry et al. 2018] alternates between one gradient descent step for \( w \) and multiple projected (sign) gradient ascent steps for \( \delta \). Hence, PGD AT is essentially MGDA applied to \( \mathbf{1} \). However, we cannot apply the convergence results by Nouiehed et al. [2019] or Jin et al. [2020] for MGDA to PGD AT. This is because \( g \) is an indicator function in the AT setting (c.f. Equation 5). Madry et al. [2018] shows the global convergence of PGD AT in the deterministic setting via Danskin’s Theorem. There are also works which show the convergence of PGD AT in terms of the loss function value [Xing et al. 2020; Gao et al. 2019; Zhang et al. 2020b].

| \( f(w) \) | \( \phi(w, \delta) \) | \( g(\delta) \) | Assumption | Convergence Rate |
|---|---|---|---|---|
| Indicator function of a convex compact set | Smooth \( -\phi(w, \cdot) \) is \( \mu \)-PL | 0 | — | \( O(1/K) \) [Nouiehed et al. 2019] |
| 0 | Lipschitz and smooth | 0 | — | \( O(1/K^{1/2}) \) [Jin et al. 2020] |

Convex Smooth Convex Weak MVI has solution \( O(1/K) \) (Ours)

Both DAT and YOPO possess a \( O(1/K^{1/2}) \) rate of convergence under smoothness and locally strongly concave assumptions. In this work, we prove a \( O(1/K) \) convergence rate for SSI-HG under smoothness and weak MVI assumptions.

### 3 PRELIMINARIES

**Notations.** We define the saddle subdifferential operator of \( \mathbf{2} \) as

\[
F(w, \delta) = \left[ \begin{array}{c} \partial f(w) + \nabla_w \phi(w, \delta) \\ \partial g(\delta) - \nabla_\delta \phi(w, \delta) \end{array} \right]
\]

and its norm as

\[
\|F(w, \delta)\| = \inf_{\gamma_f, \gamma_g} \left\| \gamma_f + \nabla_w \phi(w, \delta) \right\| \left\| \gamma_g - \nabla_\delta \phi(w, \delta) \right\|
\]

where the infimum is taken over \( \gamma_f \in \partial f(w) \) and \( \gamma_g \in \partial g(\delta) \). For a positive scalar \( \eta \), we denote \( \| \cdot \|_\eta = \| \cdot \| \). Proximal operator with some function \( \eta \) and \( \eta > 0 \) is defined as

\[
\text{prox}_k^\eta(z) = \arg \min_u h(u) + \frac{1}{2} \| u - z \|_2^2.
\]

We also use the notation \( |n| = \{1, \ldots, n\} \). Given a set \( S \), \( \Pi_S(z) \) is the indicator function which is 0 on \( z \in S \) and \( \infty \) on \( z \notin S \). \( \Pi_S[z] \) denotes the projection of \( z \) onto \( S \) w.r.t. the Euclidean norm.

**Nonconvex-nonconcave Minimax Optimization.** We are interested in finding a first-order stationary point of \( \mathbf{2} \), i.e., a point \( (w, \delta) \) which satisfies

\[
0 \in F(w, \delta) \quad \text{or equivalently,} \quad \|F(w, \delta)\| = 0.
\]

We first make the following common assumption.
Algorithm 1 SSI-HG

1: Input: \( (w^{-1}, \delta^{-1}) = (w^0, \theta^0), \sigma, \tau, \theta \)
2: for \( k = 0, 1, 2, \ldots \) do
3: \( q^k = \nabla_w \phi(w^{k-1}, \delta^{k-1}) - (n-1)\{\nabla_w \phi(w^k, \delta^k) - \nabla_w \phi(w^k, \delta^{k-1})\} \)
4: \( w^{k+1} = \text{prox}_{\sigma}^\tau [w^k - \sigma \{\nabla_w \phi(w^k, \delta^k) + \theta(\nabla_w \phi(w^k, \delta^k) - q^k)\}] \)
5: Draw \( i_k \in [n] \) uniformly at random.
6: \( \delta_{ik}^{k+1} = \text{prox}_{\gamma_{ik}}^\tau [s_{ik}^{k+1} + \tau \nabla \delta_{ik}^* \phi_i(w^{k+1}, \delta_{ik}^{k+1})] \) and \( \delta_{ik}^{k+1} = \delta_{ik}^* \) for all \( i \neq i_k \)
7: end for

We can also interpret SSI-HG as stochastic MGDA. The implicit step is equivalent to
\[
\delta_{ik}^{k+1} = \arg \min_{\delta_{ik}} g_{ik}(\delta_{ik}) - \phi_i(w^{k+1}, \delta_{ik}) + \frac{1}{2\tau} ||\delta_{ik} - \delta_{ik}^*||^2. \tag{4}
\]

The equivalence is proven in Appendix B.1. If we assume each \( \phi_i \) is smooth and use an iterative proximal method such as FISTA \cite{beck2009fast} to solve \( 4 \), SSI-HG alternates between gradient descent on \( w \) and multi-step stochastic gradient ascent on \( \delta \). Hence, SSI-HG becomes stochastic MGDA. We now present the main results of our paper. The proofs are deferred to Appendices B.3 and B.4.

Theorem 1. Suppose Assumptions 1 and 2 are true. Let \( \{w^k, \delta^k\} \) be the sequence generated by SSI-HG, and define the full-dimensional update (which only depends on \( w^k \) and \( \delta^{k-1} \))
\[
\delta^k = \text{prox}_{\gamma}^\tau [\delta^{k-1} + \tau \nabla \phi(w^k, \delta^k)].
\]

Let \( L = \max\{L_{11}, L_{12}, L_{22}\} \). If \( \theta = 1 \) and
\[
0 < \sigma \leq \frac{1}{6L}, \quad 0 < \tau \leq \frac{1}{6nL}, \quad 0 < \rho < \frac{1}{6\max\{\sigma^{-1} + 4L^2\sigma, \tau^{-1} + 12nL^2\tau\}},
\]
we have
\[
\frac{1}{K} \sum_{k=1}^K \mathbb{E}[\|F(w^k, \delta^k)\|^2] = O(1/K).
\]

---

4 SEMI-IMPLICIT HYBRID GRADIENT METHODS (SI-HGs)

Stochastic SI-HG (SSI-HG). We propose SSI-HG (Algorithm 1) to find a stationary point of (2). SSI-HG alternates between a hybrid gradient ascent step on \( w \) (line 4) and a stochastic implicit step on \( \delta \) (line 6). We remark that when \( \phi(w, \delta) \) is bilinear, the implicit step becomes explicit, and SSI-HG reduces to SPDHG with uniform sampling probability.\footnote{Let \( \phi(w, \delta) = \langle Aw, \delta \rangle \) for some matrix \( A \). Then \( \nabla_w \phi(w, \delta) = A^T \delta \) and \( \nabla \phi(w, \delta) = Aw \). Plug these relations into Algorithm 1, and compare with Algorithm 1 in the paper for SPDHG \cite{chambolle2018stochastic}.} Hence, SSI-HG generalizes SPDHG to the nonconvex-nonconcave minimax optimization setting.
**Theorem 2.** Suppose Assumptions 1 and 2 are true. Let \( \{ (w^k, \delta^k) \} \) be the sequence generated by SSI-HG. Let \( L = \max\{L_{11}, L_{12}, L_{22} \} \). If \( \theta, \sigma, \tau \) satisfy
\[
0 < \sigma \leq \frac{1}{3L}, \quad 0 < \tau \leq \frac{1}{3nL}, \quad \theta = \max \left\{ \frac{1}{1 + \mu \sigma^3}, \frac{1 + (n - 1) \mu \tau}{1 + \mu \tau} \right\},
\]
we have
\[
\mathbb{E}\|w^* - w^K\|^2 = O(\theta^K), \quad \mathbb{E}\|\delta^* - \delta^K\|^2 = O(\theta^K).
\]

Our proofs for SSI-HG are inspired by those in the work of Alacaoglu et al. (2020). Specifically, Assumption 2 or 3 allows us to characterize the one-iteration behavior of SSI-HG in the nonconvex-nonconcave scenario (Lemma 7 in Appendix B). We then use telescoping or induction to establish Theorems 1 and 2.

Since the AT problem (1) is a special case of (2) (c.f. Equation (5)), Theorem 1 improves upon the convergence rates for DAT and YOPO (Table 1). We have simplified the parameter conditions in Theorems 1 and 2 for readability. The general forms are written in Appendices B.3 and B.4.

**Deterministic SI-HG (DSI-HG).** When \( n = 1 \), SSI-HG becomes DSI-HG (Algorithm 2). All the convergence results in Theorems 1 and 2 hold for SSI-HG with expectation removed (Corollaries 3 and 4). In particular, if we interpret DSI-HG as MGDA, Corollary 3 improves upon previous guarantees for MGDA in the nonconvex-nonconcave setting (Table 2).

**Algorithm 2 DSI-HG**

1. **Input:** \((w^0, \delta^0) = (w^0, \delta^0), \sigma, \tau, \theta\).
2. for \( k = 0, 1, 2, \ldots \) do
3. \( w^{k+1} = \text{prox}^\sigma \left[ \frac{k}{k} - \sigma \{ \nabla_w \phi(w^k, \delta^k) + \theta \left( \nabla_w \phi(w^k, \delta^k) - \nabla_w \phi(w^{k-1}, \delta^{k-1}) \right) \} \right] \)
4. \( \delta^{k+1} = \text{prox}^\tau \left[ \frac{k}{k} + \tau \nabla_\delta \phi(w^{k+1}, \delta^{k+1}) \right] \)
5. end for

**Corollary 3.** Suppose Assumptions 1 and 2 are true. Let \( \{ (w^k, \delta^k) \} \) be the sequence generated by DSI-HG. Let \( L = \max\{L_{11}, L_{12}, L_{22} \} \). If \( \theta = 1 \) and
\[
0 < \sigma, \tau \leq \frac{1}{6L}, \quad 0 < \rho < \frac{1}{6 \max\{\sigma^{-1} + 4L^2 \sigma, \tau^{-1} + 12L^2 \tau\}}.
\]
we have
\[
\frac{1}{K} \sum_{k=1}^K \| F(w^k, \delta^k) \|^2 = O(1/K).
\]

**Corollary 4.** Suppose Assumptions 1 and 3 are true. Let \( \{ (w^k, \delta^k) \} \) be the sequence generated by DSI-HG. Let \( L = \max\{L_{11}, L_{12}, L_{22} \} \). If \( \theta, \sigma, \tau \) satisfy
\[
0 < \sigma, \tau \leq \frac{1}{3L}, \quad \theta = \max \left\{ \frac{1}{1 + \mu \sigma}, \frac{1}{1 + \mu \tau} \right\},
\]
we have
\[
\| w^* - w^K \|^2 = O(\theta^K), \quad \| \delta^* - \delta^K \|^2 = O(\theta^K).
\]

We again remark that we have simplified the parameter conditions for readability of the Corollaries. The general forms are written in Appendix B.5.

### 4.1 Applying SI-HGs to AT

We now extend our theoretical intuition to the AT setting. This section is inspired by works which combine theoretically established algorithms with practical algorithms or use heuristics to extend algorithms to deep learning settings. Daskalakis et al. (2018), Gidel et al. (2019), Mertikopulos et al. (2019), Nouiehed et al. (2019), Chavdarova et al. (2020), Sinha et al. (2018), Wang et al. (2019).

Denote \( B_i := \{ \delta'_i : \| \delta'_i \|_\infty \leq \epsilon \} \). The AT problem (4) can be written as
\[
\min_w \max_{\delta} \sum_{i=1}^n \phi_i(w, \delta_i) - \mathbb{I}_{B_i}(\delta_i)
\]
where
\[
\phi_i(w, \delta_i) = \frac{1}{n} \ell(x_i + \delta_i, y_i, w).
\]

When the dimension of \( \delta \) or \( w \) is large, i.e., the dataset is large or the DNN has a lot of parameters, it may be difficult to directly apply SSI-HG or DSI-HG to the AT problem. Hence, we propose minibatch SI-HG (MSI-HG, Algorithm 3 in Appendix A), which is a combination of the minibatch gradient method (Bottou et al. 2016) and DSI-HG. We also develop a heuristic for solving the implicit step in SI-HGs.

Under the AT setting (5), the minimization form of the implicit step (4) becomes
\[
\delta_{ik}^{k+1} = \arg \min_{\delta_{ik} \in B_{ik}} \phi_{ik}(w^{k+1}, \delta_{ik}) + \frac{1}{2\tau} \| \delta_{ik} - \delta_{ik}^k \|^2.
\]

Following the intuition behind Section 4 of the work by Goodfellow et al. (Goodfellow et al. 2015), we would like to use sign gradient to update \( \delta \). Sign gradient is used in many other AT methods as well (Wang et al. 2019, Zhang et al. 2019a, Madry et al. 2018, Zhang et al. 2019b). However, the quadratic penalty
in (6) may be incompatible with sign gradient. To circumvent this problem, we interpret (6) as searching for an adversarial perturbation within the proximity of $\delta_{ik}^k$. Previous works use the infinity norm to measure the distance between perturbation vectors (Yao et al., 2019; Pooaladian et al., 2020). Hence, we solve the surrogate problem

$$\delta_{ik}^{k+1} = \arg\min_{\delta_{ik} \in S_{ik}} -\phi_{ik}(w^{k+1}, \delta_{ik})$$

(7)

where

$$S_{ik} = \mathbb{B}_{ik} \cap \{ \delta_{ik} : \|\delta_{ik} - \delta_{ik}^k\|_{\infty} \leq \tau \}$$

(8)

with $T$ steps of PGD:

$$\delta_{ik}^{k,0} = \delta_{ik}^k + \text{unif}[-\tau, \tau]^d_{ik}$$

(9)

and

$$\delta_{ik}^{k,t+1} = \Pi_{S_{ik}}[\delta_{ik}^{k,t} + \eta \cdot \text{sign}(\nabla_{\delta_{ik}}\phi_{ik}(w^{k+1}, \delta_{ik}^{k,t}))]$$

(10)

for $t = 0, \ldots, T-1$, and $\delta_{ik}^{k+1} = \delta_{ik}^{k,T}$. $\tau$ and $\eta$ are hyperparameters.

5 EXPERIMENTS

We run AT on MNIST (LeCun et al., 1998), SVHN (Netzer et al., 2011), and CIFAR-10 (Krizhevsky, 2009). We denote the $T$-step PGD attack with $R$ restarts by PGD-$T\cdot R$. If $R = 0$, we omit $R$ from the name. The baseline methods are AT methods which have convergence guarantees: PGD AT, DAT, and YOPO. Following common practice, we set the number of inner iterations in PGD AT to 10 (Andriushchenko & Flammarion, 2020; Wang et al., 2019; Zhang et al., 2019a). For SI-HGs, we set $\theta = 1$ and use the smallest choices of $\tau \in (0, 2\epsilon)$ and $T \in \{2, 3, 5, 10\}$ which lead to convergence without harming the robustness. For PGD, DAT, and MSI-HG, the $\delta$ update step size $\eta$ is always set to $2.5\epsilon/T$ so $\delta$ may reach and move around on the boundary of the constraint set. For other hyperparameters, we use the recommended settings. All learning curves and statistics are produced by averaging over five random trials.

Training settings. We use a four-layer DNN (3 conv. layers with channels 16, 32, 64, and a final linear layer) on MNIST with $\epsilon = 0.4$, PreActResNet-8 (He et al., 2020) for SVHN with $\epsilon = 4/255$, and PreActResNet-18 on CIFAR-10 with $\epsilon = 8/255$. We use a single A100-SXM4-40GB to train each model. We use batch size 150 on MNIST and batch size 100 on SVHN and CIFAR-10. On each dataset, we combine each AT algorithm with SGD with momentum 0.9 plot its learning curves and statistics are produced by averaging over five random trials.

Table 3: Accuracy (%) on natural and adversarial examples at the final iteration.

| Method   | MNIST       | SVHN       | CIFAR-10   |
|----------|-------------|------------|------------|
|          | Natural     | PGD-20     | PGD-50     |
|          | Natural     | PGD-20     | PGD-50     |
|          | Natural     | PGD-20     | PGD-50     |
|-----------|-------------|------------|------------|
| PGD AT    | 94.68±0.21  | 54.23±4.27 | 44.30±4.60 |
| DAT       | 93.27±0.71  | 16.73±6.17 | 10.00±3.87 |
| YOPO      | 97.73±0.09  | 24.92±12.29| 14.63±10.09|
| MSI-HG (Ours) | 94.89±0.63  | 62.34±3.33 | 44.51±2.04 |

Table 4: Accuracy (%) on natural and adversarial examples at the moment of best robust accuracy. We do not report accuracies on adversarial examples generated by PGD-50-10, as it was too expensive to run PGD-50-10 at every iteration of training.

| Method   | MNIST       | SVHN       | CIFAR-10   |
|----------|-------------|------------|------------|
|          | Natural     | PGD-20     | PGD-50     |

Figure 1: Learning curves of AT algorithms. Solid line denotes natural accuracy and dotted line denotes accuracy on adversarial examples generated by PGD-20. On SVHN, the natural accuracy curves for PGD AT and DAT overlap near the end.

Figure 2: Processed learning curves of AT algorithms. At iteration $K$, we plot the natural and robust accuracies of the iteration $\leq K$ which had the best robust accuracy. Solid line denotes natural accuracy and dotted line denotes accuracy on adversarial examples generated by PGD-20. On SVHN, the natural accuracy curves for PGD AT and DAT overlap near the end.
at epoch 15, peaks at epoch 20 with value 0.02, and
decays to zero at epoch 30. We found that YOPO did not
converge under the triangular and cyclic learning rate
schedules. Hence, we follow the settings recommended
by the authors for YOPO on SVHN experiments. On
CIFAR-10, we reuse the best accuracies reported by
the authors of YOPO (c.f. Table 2 in (Zhang et al.,
2019a)). Further training settings are described in Ap-
pendix C.

Experiment results. In Figure 1, we plot the learn-
ing curves of AT algorithms. On all datasets, we see
acceleration for MSI-HG. For YOPO and DAT, the
natural accuracies rise faster than those of MSI-HG,
but robust accuracies grow extremely slowly. This
is undesirable, since our goal is faster convergence to
adversarially robust DNNs. On MNIST and SVHN,
MSI-HG shows acceleration during the first half of the
training process. If we examine the magnified learning
curves on CIFAR-10, MSI-HG shows faster conver-
gence than PGD AT at iterations 6k to 8k and 10k to
15k. As a result, the accuracies of PGD AT at epoch
30 is lower than those of MSI-HG at epoch 15. If we
process the learning curves to reduce oscillations (Fig-
ure 2), acceleration for MSI-HG is even more evident.
We note that MSI-HG uses at most ten steps in the
inner loop, so its computational cost is similar to or
better than that of PGD AT.

We also report natural and robust accuracies in Tables
6 and 7. MSI-HG achieves better robustness than the
baseline methods on all datasets. YOPO achieves
higher natural accuracy at the cost of lower robustness.
On MNIST, robustness for YOPO is especially poor.
MSI-HG beat PGD AT and DAT in terms of both
natural and robust accuracies.

6 DISCUSSION ON THE
LIMITATIONS OF OUR WORK

6.1 Theoretical Assumptions

Here, we discuss and attempt to justify the theoretical
assumptions used in our work.

Assumption 1. Assumption 1 is generally false in the
deep learning setting. For instance, the assump-
tion that the coupling function φ has Lipschitz con-
tinuous gradients is false when we train DNNs which use
non-differentiable operations such as ReLU or max-
pooling. Still, many works show that algorithms with
such theoretical results perform surprisingly well in the
deep learning setting (Daskalakis et al., 2018; Gidel
et al., 2019; Mertikopoulos et al., 2019; Nouiehed et al.,
2019; Chavdarova et al., 2020; Wang et al., 2019;
Zhang et al., 2020a). We speculate that this is be-
cause the assumptions hold approximately or locally
when we train DNNs. For example, a recent work has shown that semi-smoothness, an approximate ver-
sion of smoothness, holds for overparametrized ReLU
DNNs (Allen-Zhu et al., 2018). Thus, even if we have to
work under some restrictive assumptions, it is cru-
cial that we continue to develop theoretical grounds
for AT methods.

Assumption 2. The relation between MVI and AT is a non-trivial research topic by itself, but we try
our best to justify the MVI condition here. First, the
MVI condition is already weaker than other assump-
tions such as pseudo-monotonicity, monotonicity, or
coherence (Mertikopoulos et al., 2019). In fact, we
use the even weaker weak MVI condition. Second,
our algorithms developed under the MVI condition have
shown good performance when applied to deep learn-
ing (Gidel et al., 2019; Mertikopoulos et al., 2019; Liu
et al., 2020a). Finally, Liu et al. (2020a) has pointed
out that the MVI condition holds while using SGD to
learn neural nets for minimization. As nonconvex-
nonconcave minimax optimization is in general in-
tractable (Diakonikolas & Daskalakis, 2021), we be-
lieve the MVI condition is an adequate choice to de-
velop new AT algorithms in a principled manner.

6.2 Per-Iteration Costs

Due to the full-gradient update in w, the per-iteration
cost for SSI-HG is larger than per-iteration costs of
doubly-stochastic methods. Hence, it is necessary
to establish theoretical results for methods such as
MSI-HG. Based on the experiments, we cautiously
conjecture that MSI-HG also has a rate better than
O(1/K^1/2). It may be possible to use ideas from our
proofs for SSI-HG and DSI-HG to prove the conver-
gence of MSI-HG, but we leave this for future work.

6.3 Memorization of δ

Although we introduced hybrid gradient methods and
PGD AT / DAT / YOPO as the same class of algo-
rithm (MGDA), they are different in the aspect that
PGD AT / DAT / YOPO does not memorize δ but hy-
brid gradient methods do. This is because PGD AT / DAT / YOPO randomly initializes δ at every iteration.
This may seem like a drawback of the hybrid gradient
methods, yet this memory of δ is what allows us to ap-

On CIFAR-10, to generate PGD-20 adversarial ex-
amples, the authors of YOPO use η = 2/255 while we
use η = 1/255. However, PGD-50-10 accuracy for MSI-
HG is higher than PGD-20 accuracy for YOPO. Thus,
PreActResNet-18 trained by MSI-HG is indeed more ro-
bust than those trained by YOPO.

Wang et al. (Wang et al., 2019) also considers this
perspective.
ply the momentum-like update (line 3 of Algorithms [1] and [2]) and thus obtain better convergence rates. This intuition is reflected in the faster convergence of SI-HG in the adversarial training (AT) experiments.

7 CONCLUSION

In this work, we introduced SI-HGs to solve nonconvex-nonconcave minimax problems separable in the maximization variable. We proved that SI-HGs achieve the convergence rate $O(1/K)$ which improves upon the convergence rate $O(1/K^{1/2})$ of YOPO and DAT. Our work also improved upon previous convergence results for MGDA. Experiments showed that a practical variant of SI-HGs indeed converges faster and achieves better robustness than other AT methods. Finally, we discussed the limitations of our work, and proposed future directions of research.

We generally expect positive outcomes from this work, since robustness and efficiency are desirable properties of machine learning systems. Adversarially robust DNNs are more likely to be resistant to malicious input manipulations than their naturally trained counterparts. Algorithms which converge fast consume less resource than other algorithms with similar per-iteration costs.

7:     $\nabla_{nk+i} = 2 \nabla_w \phi_i(w_{nk+i-1}, \delta_i^{nk+i}) - \nabla_w \phi_{i-1}(w_{nk+i-2}, \delta_{i-1}^{nk+i-1})$ 
8:     $w_{nk+i} = w_{nk+i-1} - \sigma \cdot \text{GD} \left[ \nabla_{nk+i-1}, \rho, nk + i \right]$ 
9:   end for
10: end for

We also use $T$ steps of PGD to approximate line 5 in Algorithms 3 and 4.
B MISCELLANEOUS PROOFS

B.1 Proof of the equivalence between the implicit step and Equation (4)

By the definition of the proximal operator, line 6 of SSI-HG (Algorithm 1) is

\[
\delta_{i_k}^{k+1} = \arg \min_{\delta_{i_k}} g_{i_k}(\delta_{i_k}) + \frac{1}{2}\|\delta_{i_k} - \{\delta_{i_k}^k + \tau_k \nabla_{\delta_{i_k}} \phi_{i_k}(w^{k+1}, \sigma^{k+1})\}\|_2^{-1},
\]

which is equivalent to

\[
0 \in \partial g_{i_k}(\delta_{i_k}^{k+1}) + \tau_k^{-1}[\delta_{i_k}^{k+1} - \{\delta_{i_k}^k + \tau_k \nabla_{\delta_{i_k}} \phi_{i_k}(w^{k+1}, \sigma^{k+1})\}].
\]

This is the optimality condition for \( (4) \).

\( B.2 \) One-iteration result for SSI-HG

We also define the following representation of SSI-HG with full dimensional updates

\[
q^k = \nabla_w \phi(w^{k-1}, \delta^{k-1}) - (n-1)\{\nabla_w \phi(w^k, \delta^k) - \nabla_w \phi(w^k, \delta^{k-1})\},
\]

\[
w^{k+1} = \text{prox}_{\gamma_f}^\tau [w^k - \sigma \{\nabla_w \phi(w^k, \delta^k) + \theta_k(\nabla_w \phi(w^k, \delta^k) - q^k)\}],
\]

\[
\delta_{i_k}^{k+1} = \text{prox}_{\gamma_{i_k}}^\tau [\delta_{i_k}^k + \tau \nabla_{\delta_{i_k}} \phi_{i_k}(w^{k+1}, \sigma^{k+1})].
\]

The optimality conditions for \( w^{k+1} \) and \( \delta_{i_k}^{k+1} \) are

\[
0 = \gamma_f^{k+1} + \sigma^{-1}[w^{k+1} - w^k + \sigma \{\nabla_w \phi(w^k, \delta^k) + \theta(\nabla_w \phi(w^k, \delta^k) - q^k)\}]
\]

\[
0 = \gamma_{i_k}^{k+1} + \tau^{-1}(\delta_{i_k}^{k+1} - \delta_{i_k}^k - \tau \nabla_{\delta_{i_k}} \phi_{i_k}(w^{k+1}, \sigma^{k+1}))
\]

for some \( \gamma_f^{k+1} \in \partial f(w^{k+1}) \) and \( \gamma_{i_k}^{k+1} \in \partial g_{i_k}(\delta_{i_k}^{k+1}) \). Note that

\[
\gamma_{i_k}^{k+1} := (\hat{\gamma}_{i_k}^{k+1}, \ldots, \hat{\gamma}_{i_k}^{k+1}) \in \partial g_{i_k}(\delta_{i_k}^{k+1})
\]

so from \( (13) \),

\[
0 = \hat{\gamma}_{i_k}^{k+1} + \tau^{-1}(\hat{\gamma}_{i_k}^{k+1} - \delta_{i_k}^k - \tau \nabla_{\delta_{i_k}} \phi_{i_k}(w^{k+1}, \sigma^{k+1})).
\]

We also note that the optimality condition for \( \delta_{i_k}^{k+1} \) is

\[
0 = \gamma_g^{k+1} + \tau^{-1}(\delta_{i_k}^{k+1} - \delta_{i_k}^k - \tau \nabla_{\delta_{i_k}} \phi_{i_k}(w^{k+1}, \sigma^{k+1}))
\]

for some \( \gamma_g^{k+1} \in \partial g_{i_k}(\delta_{i_k}^{k+1}) \). We start with some technical Lemmas.

**Lemma 5.** For any \( \delta \in \mathbb{R}^{d_1} \times \cdots \times \mathbb{R}^{d_n} \) and any function \( r(\delta) = \sum_{i=1}^n r_i(\delta_i) \),

\[
r(\delta^{k+1}) = \mathbb{E}_k r(\delta^{k+1}) + (n-1)\{\mathbb{E}_k r(\delta^{k+1}) - r(\delta^k)\}
\]

\[
\|\delta - \delta^{k+1}\|_{l^{-1}}^2 = n \mathbb{E}_k \|\delta - \delta^{k+1}\|_{l^{-1}}^2 - n\|\delta - \delta^k\|_{l^{-1}}^2 - n\|\delta - \delta^k\|_{l^{-1}}^2 + \|\delta - \delta^k\|_{l^{-1}}^2,
\]

\[
\|\delta^{k+1} - \delta^k\|_{l^{-1}}^2 = n \mathbb{E}_k \|\delta^{k+1} - \delta^k\|_{l^{-1}}^2
\]

**Proof.** Let us observe that

\[
\mathbb{E}_k r_i(\delta_i^{k+1}) = \frac{1}{n} r_i(\delta_i^{k+1}) + \left(1 - \frac{1}{n}\right) r_i(\delta_i^k).
\]

Summing the above equation over \( i \), multiplying both sides by \( n \), and rearranging the terms yields \( (18) \). Using \( r(\delta) = \|\delta - \delta^{k+1}\|_{l^{-1}}^2 \) yields \( (19) \). Finally, plugging in \( \delta = \delta^k \) into \( (19) \) yields \( (20) \).
Lemma 6. Assume $\sigma > 0$, $\tau > 0$, $\theta \in (0, 1]$, and define
\[
\kappa = \max\{L_{12}(\sigma \tau n)^{1/2}, L_{11} \sigma\}.
\]
We then have
\[
|\langle w^k - w^{k+1}, \nabla_w \phi(w^k, \delta^k) - \phi^k \rangle |
\leq \kappa \Vert w^{k+1} - w^k \Vert_{\sigma-1}^2 + \frac{\kappa}{2} \Vert w^k - w^{k-1} \Vert_{\sigma-1}^2 + \frac{\kappa}{2} \Vert \delta^k - \delta^{k-1} \Vert_{\tau-1}^2.
\]
(21)
\[
\leq \frac{\kappa}{\theta} \Vert w^{k+1} - w^k \Vert_{\sigma-1}^2 + \frac{\kappa}{2} \Vert w^k - w^{k-1} \Vert_{\sigma-1}^2 + \frac{\kappa}{2} \Vert \delta^k - \delta^{k-1} \Vert_{\tau-1}^2.
\]
(22)

Proof. We note that since $\theta \in (0, 1]$, it suffices to prove (21). By the definition of $\phi^k$,
\[
\langle w^k - w^{k+1}, \nabla_w \phi(w^k, \delta^k) - \phi^k \rangle
= \langle w^k - w^{k+1}, \nabla_w \phi(w^k, \delta^k) \rangle + (n-1)\{\nabla_w \phi(w^k, \delta^k) - \nabla_w \phi(w^k, \delta^{k-1}\}) - \nabla_w \phi(w^{k-1}, \delta^{k-1})
= n\langle w^k - w^{k+1}, \nabla_w \phi(w^k, \delta^{k-1}) \rangle + \langle w^k - w^{k+1}, \nabla_w \phi(w^k, \delta^{k-1}) \rangle - \nabla_w \phi(w^{k-1}, \delta^{k-1})\}.
\]
(23)
We now bound the two inner products in (23). The first inner product can be bounded as
\[
\kappa^{-1}|\langle w^k - w^{k+1}, \nabla_w \phi(w^k, \delta^k) - \nabla_w \phi(w^k, \delta^{k-1}) \rangle |
\leq (L_{12}^2 \sigma \tau n)^{-1/2}|\langle w^k - w^{k+1}, \nabla_w \phi(w^k, \delta^k) - \nabla_w \phi(w^k, \delta^{k-1}) \rangle |
\leq L_{12}^2 \sigma \tau n^{-1/2} \Vert w^{k+1} - w^k \Vert \Vert \nabla_w \phi(w^k, \delta^k) - \nabla_w \phi(w^{k-1}, \delta^{k-1}) \Vert
\leq (\sigma \tau n)^{-1/2} \Vert w^{k+1} - w^k \Vert \Vert \delta^k - \delta^{k-1} \Vert
\leq \frac{1}{2n} \Vert w^{k+1} - w^k \Vert_{\sigma-1}^2 + \frac{1}{2} \Vert \delta^k - \delta^{k-1} \Vert_{\tau-1}^2
\]
(24)
where we have used the definition of $\kappa$ at the first inequality, Cauchy-Schwarz inequality at the second inequality, Lipschitz continuity of $\nabla_w \phi$ at the third inequality, and Young’s inequality at the last inequality.

The second inner product can be bounded as
\[
\kappa^{-1}|\langle w^k - w^{k+1}, \nabla_w \phi(w^k, \delta^{k-1}) \rangle |
\leq (L_{11}^2 \sigma^2)^{-1/2}|\langle w^k - w^{k+1}, \nabla_w \phi(w^k, \delta^{k-1}) \rangle |
\leq L_{11}^2 \sigma^2^{-1/2} \Vert w^{k+1} - w^k \Vert \Vert \nabla_w \phi(w^k, \delta^{k-1}) - \nabla_w \phi(w^{k-1}, \delta^{k-1}) \Vert
\leq \sigma^2^{-1/2} \Vert w^{k+1} - w^k \Vert \Vert w^k - w^{k-1} \Vert
\leq \frac{1}{2} \Vert w^{k+1} - w^k \Vert_{\sigma-1}^2 + \frac{1}{2} \Vert w^k - w^{k-1} \Vert_{\sigma-1}^2
\]
(25)
where we have used the definition of $\kappa$ at the first inequality, Cauchy-Schwarz inequality at the second inequality, Lipschitz continuity of $\nabla_w \phi$ at the third inequality, and Young’s inequality at the last inequality.

It follows that
\[
|\langle w^k - w^{k+1}, \nabla_w \phi(w^k, \delta^k) - \phi^k \rangle |
\leq n|\langle w^k - w^{k+1}, \nabla_w \phi(w^k, \delta^k) - \nabla_x \phi(w^k, \delta^{k-1}) \rangle |
+ |\langle w^k - w^{k+1}, \nabla_w \phi(w^k, \delta^{k-1}) \rangle |
\leq \kappa \Vert w^{k+1} - w^{k+1} \Vert_{\sigma-1}^2 + \frac{\kappa}{2} \Vert w^k - w^{k-1} \Vert_{\sigma-1}^2 + \frac{\kappa}{2} \Vert \delta^k - \delta^{k-1} \Vert_{\tau-1}^2,
\]
where we have applied the triangle inequality to (23) at the first inequality and have used (21) and (22) at the second inequality.
Lemma 7 (One-Iteration Result). Assume $\sigma > 0$, $\tau > 0$, $\theta > 0$. We then have for any $(w, \delta)$,

\[
0 \geq \left[ s_{f}^{k+1} + \nabla_{w} \phi(w^{k+1}, \delta^{k+1}) \right]^T \left[ w^{k+1} - w \right] + \nabla_{w} \phi(w^{k+1}, \delta^{k+1}) - \nabla_{w} \phi(w^{k}, \delta^{k}) - q^{k}
+ \frac{1}{2} \| w - w^{k+1} \|^2_{\sigma^{-1}} + \frac{1}{2} \| w^{k} - w^{k+1} \|^2_{\sigma^{-1}} - \frac{1}{2} \| w - w^{k} \|^2_{\sigma^{-1}} - \frac{\kappa \theta}{2} \| w - w^{k} - \delta \|^2_{\sigma^{-1}}.
\]

Proof. Optimality condition \[14\] implies that

\[
0 = \langle w^{k+1} - w, \gamma_{f}^{k+1} + \sigma^{-1} \{ w^{k+1} - w^{k} + \sigma \{ \nabla_{w} \phi(w^{k}, \delta^{k}) + \theta(\nabla_{w} \phi(w^{k}, \delta^{k}) - q^{k}) \} \} \rangle
+ \langle w^{k+1} - w, \gamma_{f}^{k+1} + \nabla_{w} \phi(w^{k+1}, \delta^{k+1}) \rangle - \langle w^{k+1} - w, \nabla_{w} \phi(w^{k}, \delta^{k}) - \nabla_{w} \phi(w^{k+1}, \delta^{k+1}) \rangle
+ \sigma^{-1} \langle w^{k+1} - w, w^{k+1} - w^{k} \rangle
- \theta \langle w^{k} - w^{k+1}, \nabla_{w} \phi(w^{k}, \delta^{k}) - q^{k} \rangle - \theta \langle w^{k+1} - w^{k}, \nabla_{w} \phi(w^{k}, \delta^{k}) - q^{k} \rangle
+ \frac{1}{2} \| w - w^{k+1} \|^2_{\sigma^{-1}} + \frac{1}{2} \| w^{k} - w^{k+1} \|^2_{\sigma^{-1}} - \frac{1}{2} \| w - w^{k} \|^2_{\sigma^{-1}}. \tag{26}
\]

By \[18\] with $r(\delta) = \nabla_{w} \phi(w^{k+1}, \delta)$, we have

\[
\nabla_{w} \phi(w^{k}, \delta^{k}) - \nabla_{w} \phi(w^{k+1}, \delta^{k+1})
= \nabla_{w} \phi(w^{k}, \delta^{k}) - (n - 1) \{ \mathbb{E}_{k} \nabla_{w} \phi(w^{k+1}, \delta^{k+1}) - \nabla_{w} \phi(w^{k+1}, \delta^{k}) \}
= \mathbb{E}_{k} q^{k+1} - \mathbb{E}_{k} \nabla_{w} \phi(w^{k+1}, \delta^{k+1}) \tag{27}
\]

and by plugging this into \[26\] and using linearity of expectation, we obtain

\[
0 = \langle w^{k+1} - w, \gamma_{f}^{k+1} + \nabla_{w} \phi(w^{k+1}, \delta^{k+1}) \rangle + \mathbb{E}_{k} \langle w^{k+1} - w^{k}, \nabla_{w} \phi(w^{k+1}, \delta^{k+1}) - q^{k} \rangle
- \theta \langle w^{k} - w^{k+1}, \nabla_{w} \phi(w^{k}, \delta^{k}) - q^{k} \rangle - \theta \langle w^{k+1} - w^{k}, \nabla_{w} \phi(w^{k}, \delta^{k}) - q^{k} \rangle
+ \frac{1}{2} \| w - w^{k+1} \|^2_{\sigma^{-1}} + \frac{1}{2} \| w^{k} - w^{k+1} \|^2_{\sigma^{-1}} - \frac{1}{2} \| w - w^{k} \|^2_{\sigma^{-1}}. \tag{28}
\]

Applying \[22\] of Lemma \[6\] to \[28\], we have

\[
0 \geq \langle w^{k+1} - w, \gamma_{f}^{k+1} + \nabla_{w} \phi(w^{k+1}, \delta^{k+1}) \rangle + \mathbb{E}_{k} \langle w^{k+1} - w^{k}, \nabla_{w} \phi(w^{k+1}, \delta^{k+1}) - q^{k} \rangle
- \theta \langle w^{k} - w^{k+1}, \nabla_{w} \phi(w^{k}, \delta^{k}) - q^{k} \rangle + \frac{1}{2} \| w - w^{k+1} \|^2_{\sigma^{-1}} + \frac{1}{2} \| w^{k} - w^{k+1} \|^2_{\sigma^{-1}} - \frac{1}{2} \| w - w^{k} \|^2_{\sigma^{-1}}
- \frac{\kappa \theta}{2} \| w - w^{k} - \delta \|^2_{\sigma^{-1}} - \frac{n \kappa \theta}{2} \| \delta - \delta^{k-1} \|^2_{\sigma^{-1}}. \tag{29}
\]

Optimality condition \[16\] implies that

\[
0 = \langle \delta^{k+1} - \delta, \gamma_{f}^{k+1} + \tau^{-1} (\delta^{k+1} - \delta - \tau \nabla_{\delta} \phi(w^{k+1}, \delta^{k+1})) \rangle
= \langle \delta^{k+1} - \delta, \gamma_{f}^{k+1} + \nabla_{\delta} \phi(w^{k+1}, \delta^{k+1}) \rangle + \tau^{-1} \langle \delta^{k+1} - \delta, \delta^{k+1} - \delta \rangle
= \langle \delta^{k+1} - \delta, \gamma_{f}^{k+1} + \nabla_{\delta} \phi(w^{k+1}, \delta^{k+1}) \rangle + \frac{1}{2} \| \delta - \delta^{k+1} \|^2_{\tau^{-1}} + \frac{1}{2} \| \delta^{k+1} - \delta \|^2_{\tau^{-1}} - \frac{1}{2} \| \delta - \delta^{k} \|^2_{\tau^{-1}}
= \langle \delta^{k+1} - \delta, \gamma_{f}^{k+1} + \nabla_{\delta} \phi(w^{k+1}, \delta^{k+1}) \rangle
+ \frac{n}{2} \mathbb{E}_{k} \| \delta - \delta^{k+1} \|^2_{\tau^{-1}} + \frac{n}{2} \mathbb{E}_{k} \| \delta^{k+1} - \delta \|^2_{\tau^{-1}} - \frac{n}{2} \| \delta - \delta^{k} \|^2_{\tau^{-1}}. \tag{30}
\]

where we have used \[19\] and \[20\] at the last equality. Adding \[29\] and \[30\] concludes the proof. \qed
B.3 Proof of Theorem 1

Lemma 8. Let $\theta = 1$. We then have

\[
\|g_{k+1} + \nabla \phi(w_{k+1}, \hat{\delta}_{k+1})\|^2 \leq 3(\sigma^{-1} + 2L^2_{11}\sigma)\|w_{k+1} - w_k\|^2_{\sigma^{-1}} + 6L^2_{11}\sigma\|w_k - w_{k-1}\|^2_{\sigma^{-1}} + n(\tau^{-1} + 6nL^2_{12}\tau)E_k\|\delta_{k+1} - \delta_k\|^2_{\tau^{-1}} + 6n^2L^2_{12}\tau\|\delta_k - \delta_{k-1}\|^2_{\tau^{-1}}.
\]

Proof. First, observe that

\[
\|g_{k+1} + \nabla \phi(w_{k+1}, \hat{\delta}_{k+1})\|^2
= \|\sigma^{-1}(-w_{k+1} + w_k) + E_k\{\nabla \phi(w_{k+1}, \hat{\delta}_{k+1}) - q_{k+1}\} - \{\nabla \phi(w_k, \delta_k) - q_k\}\|^2
\leq 3\sigma^{-1}\|w_{k+1} - w_k\|^2_{\sigma^{-1}} + 3\|E_k\{\nabla \phi(w_{k+1}, \hat{\delta}_{k+1}) - q_{k+1}\}\|^2 + 3\|\nabla \phi(w_k, \delta_k) - q_k\|^2
\leq 3\sigma^{-1}\|w_{k+1} - w_k\|^2_{\sigma^{-1}} + 3\|E_k\|\|\nabla \phi(w_{k+1}, \hat{\delta}_{k+1}) - q_{k+1}\|^2 + 3\|\nabla \phi(w_k, \delta_k) - q_k\|^2
\]

where we have used the combination of \eqref{14} and \eqref{27} at the first equality and Jensen’s inequality at the first and second inequalities. We have

\[
\|\nabla \phi(w_k, \delta_k) - q_k\|^2
= \|\nabla \phi(w_k, \delta_k) - \nabla \phi(w_k, \delta_k)\|^2 + \|\nabla \phi(w_k, \delta_k) - \nabla \phi(w_{k-1}, \delta_k)\|^2
\leq 2n^2\|\nabla \phi(w_k, \delta_k) - \nabla \phi(w_{k-1}, \delta_k)\|^2 + 2\|\nabla \phi(w_k, \delta_k) - \nabla \phi(w_{k-1}, \delta_k)\|^2
\leq 2n^2L^2_{12}\|\delta_k - \delta_{k-1}\|^2_{\tau^{-1}} + 2L^2_{11}\|w_k - w_{k-1}\|^2
\leq 2n^2L^2_{12}\tau\|\delta_k - \delta_{k-1}\|^2_{\tau^{-1}} + 2L^2_{11}\|w_k - w_{k-1}\|^2_{\sigma^{-1}}.
\]

where we have used the definition of $q_k$ at the first equality, Jensen’s inequality at the first inequality, and Lipschitz continuity of $\nabla \phi(w, \delta)$ at the second inequality. Similarly,

\[
\|\nabla \phi(w_{k+1}, \hat{\delta}_{k+1}) - q_{k+1}\|^2 \leq 2n^2L^2_{12}\tau\|\delta_{k+1} - \delta_k\|^2_{\tau^{-1}} + 2L^2_{11}\|w_{k+1} - w_k\|^2_{\sigma^{-1}}.
\]

Applying \eqref{32} and \eqref{33} to \eqref{31}, we obtain

\[
\|g_{k+1} + \nabla \phi(w_{k+1}, \hat{\delta}_{k+1})\|^2 \leq 3(\sigma^{-1} + 2L^2_{11}\sigma)\|w_{k+1} - w_k\|^2_{\sigma^{-1}} + 6L^2_{11}\sigma\|w_k - w_{k-1}\|^2_{\sigma^{-1}} + 6n^2L^2_{12}\tau\|\delta_k - \delta_{k-1}\|^2_{\tau^{-1}} + 6n^2L^2_{12}\tau\|\delta_k - \delta_{k-1}\|^2_{\tau^{-1}}.
\]

We also have

\[
\|g_{k+1} - \nabla \phi(w_{k+1}, \hat{\delta}_{k+1})\|^2 = \|\tau^{-1}(-\hat{\delta}_{k+1} + \delta_k)\|^2
= \tau^{-1}\|\hat{\delta}_{k+1} - \delta_k\|^2_{\tau^{-1}}
= n\tau^{-1}\|\delta_{k+1} - \delta_k\|^2_{\tau^{-1}}
\]

where we have used \eqref{16} at the first equality and \eqref{20} at the third equality. Combining \eqref{34} and \eqref{35} concludes the proof. \hfill \Box
Theorem 1. Suppose Assumptions 1 and 2 are true. Let \( \{w^k, \delta^k\} \) be the sequence generated by SSI-HG, and define the full-dimensional update (which only depends on \( w^k \) and \( \delta^{k-1} \))
\[ \dot{\delta}^k = \text{prox}^\tau_{\delta} [\delta^{k-1} + \tau \nabla \phi(w^k, \dot{\delta}^k)]. \]

If \( \theta = 1 \) and \( \rho > 0, \sigma > 0, \tau > 0 \) satisfy
\[ \max \{L_{12}(\sigma \tau n)^{1/2}, L_{11} \sigma \} < \min \{1/3 - \rho (\sigma^{-1} + 4L_{11}^2 \sigma), 1 - \rho (\tau^{-1} + 12 n L_{12}^2 \tau) \}\]
we have
\[ \frac{1}{K} \sum_{k=1}^K \mathbb{E} \|F(w^k, \dot{\delta}^k)\|^2 = O(1/K). \]

Proof. Let \( (w^*, \delta^*) \) be a solution of the weak MVI problem (which exists by Assumption 2). Then
\[
0 \geq \begin{bmatrix} \gamma^* f^{k+1} + \nabla w \phi(w^{k+1}, \delta^{k+1}) \\ \hat{z}^+ - \nabla \phi(w^{k+1}, \delta^{k+1}) \end{bmatrix}^T \begin{bmatrix} w^{k+1} - w^* \\ \delta^{k+1} - \delta^* \end{bmatrix} + \mathbb{E}_k \langle w^* - w^{k+1}, \nabla \phi(w^{k+1}, \delta^{k+1}) - q^{k+1} \rangle - \langle w^* - w^k, \nabla \phi(w^k, \delta^k) - q^k \rangle \\
+ \frac{1}{2} \|w^* - w^{k+1}\|_{\sigma^{-1}}^2 + \left( \frac{1}{2} - 2\kappa \right) \|w^{k+1} - w^k\|_{\sigma^{-1}}^2 - \frac{1}{2} \|w^* - w^k\|_{\sigma^{-1}}^2 - \frac{\kappa}{2} \|w^k - w^{k-1}\|_{\sigma^{-1}}^2 \\
+ \frac{n}{2} \mathbb{E}_k \|\delta^* - \delta^{k+1}\|_{\tau^{-1}}^2 + \left( \frac{n}{2} \right) \mathbb{E}_k \|\delta^{k+1} - \delta^k\|_{\tau^{-1}}^2 - \frac{n}{2} \|\delta^* - \delta^k\|_{\tau^{-1}}^2 - \frac{n}{2} \|\delta^k - \delta^{k-1}\|_{\tau^{-1}}^2 \geq \mathbb{E}_k \langle w^* - w^{k+1}, \nabla \phi(w^{k+1}, \delta^{k+1}) - q^{k+1} \rangle - \langle w^* - w^k, \nabla \phi(w^k, \delta^k) - q^k \rangle \\
+ \frac{1}{2} \|w^* - w^{k+1}\|_{\sigma^{-1}}^2 + \left( \frac{1}{2} - 2\kappa \right) \|w^{k+1} - w^k\|_{\sigma^{-1}}^2 - \frac{1}{2} \|w^* - w^k\|_{\sigma^{-1}}^2 - \frac{\kappa}{2} \|w^k - w^{k-1}\|_{\sigma^{-1}}^2 \\
+ \frac{n}{2} \mathbb{E}_k \|\delta^* - \delta^{k+1}\|_{\tau^{-1}}^2 + \left( \frac{n}{2} \right) \mathbb{E}_k \|\delta^{k+1} - \delta^k\|_{\tau^{-1}}^2 - \frac{n}{2} \|\delta^* - \delta^k\|_{\tau^{-1}}^2 - \frac{n}{2} \|\delta^k - \delta^{k-1}\|_{\tau^{-1}}^2 \]
\]
where we have used Lemma 3 with \( \theta = 1 \) at the first inequality, Assumption 2 at the second inequality, and Lemma 8 at the third inequality. Rearranging and adding and subtracting some terms in (36), we obtain
\[
\langle w^* - w^k, \nabla \phi(w^k, \delta^k) - q^k \rangle + \frac{1}{2} \|w^* - w^k\|_{\sigma^{-1}}^2 + \frac{n}{2} \|\delta^* - \delta^k\|_{\tau^{-1}}^2 \\
+ \left( \frac{\kappa + \rho(6L_{12}^2 \tau)}{2} \right) \|w^k - w^{k-1}\|_{\sigma^{-1}}^2 + \frac{n}{2} \|\delta^* - \delta^{k+1}\|_{\tau^{-1}}^2 + \frac{n\{1 - 2\kappa + 6nL_{12}^2 \tau)\}}{2} \mathbb{E}_k \|\delta^{k+1} - \delta^k\|_{\tau^{-1}}^2 \\
\geq \mathbb{E}_k \langle w^* - w^{k+1}, \nabla \phi(w^{k+1}, \delta^{k+1}) - q^{k+1} \rangle + \frac{1}{2} \|w^* - w^{k+1}\|_{\sigma^{-1}}^2 + \frac{n}{2} \mathbb{E}_k \|\delta^* - \delta^{k+1}\|_{\tau^{-1}}^2 \\
+ \left( \frac{\kappa + \rho(6L_{12}^2 \tau)}{2} \right) \|w^{k+1} - w^k\|_{\tau^{-1}}^2 + \frac{n\{1 - 2\kappa + 6nL_{12}^2 \tau)\}}{2} \mathbb{E}_k \|\delta^{k+1} - \delta^k\|_{\tau^{-1}}^2 \\
+ \frac{n}{2} \|\delta^* - \delta^k\|_{\tau^{-1}}^2 + \frac{n\{1 - 2\kappa + 6nL_{12}^2 \tau)\}}{2} \mathbb{E}_k \|\delta^{k+1} - \delta^k\|_{\tau^{-1}}^2. \]
(37)
Taking full expectation over (37), summing both sides over \(k = 0, \ldots, K - 1\), and using \((w^{-1}, \delta^{-1}) = (w^0, \delta^0)\), we obtain

\[
\frac{1}{2}\|w^* - w^0\|_\sigma^2 + \frac{n}{2}\|\delta^* - \delta^0\|_\tau^2 - \frac{\rho L_1^2}{2} \frac{\|w^K - w^{-1}\|_\sigma^2 + \frac{\rho (6nL_1^2\tau)}{2} \|\delta^K - \delta^{-1}\|_\tau^2}{2} \\
+ \frac{(1 - 3\kappa - 3\rho(\sigma^{-1} + 4L_1^2\sigma))}{2} \sum_{k=0}^{K-1} \|w^{k+1} - w^k\|_\sigma^2 + \frac{n\{1 - \kappa - \rho(\tau^{-1} + 12nL_1^2\tau)\}}{2} \sum_{k=0}^{K-1} \|\delta^{k+1} - \delta^k\|_\tau^2.
\]

By reasoning similarly as the proof of Lemma 6, we have

\[
\|\langle w^* - w^K, \nabla w_\phi(w^K, \delta^K) - q^K \rangle\| \leq \kappa \|w^* - w^K\|_\sigma^2 + \frac{\kappa}{2} \|w^K - w^{-1}\|_\sigma^2 + \frac{\kappa}{2} \|\delta^K - \delta^{-1}\|_\tau^2
\]

and so (38) implies

\[
\frac{1}{2}\|w^* - w^0\|_\sigma^2 + \frac{n}{2}\|\delta^* - \delta^0\|_\tau^2 - \frac{\rho L_1^2}{2} \frac{\|w^K - w^{-1}\|_\sigma^2 + \frac{\rho (6nL_1^2\tau)}{2} \|\delta^K - \delta^{-1}\|_\tau^2}{2} \\
+ \frac{(1 - 3\kappa - 3\rho(\sigma^{-1} + 4L_1^2\sigma))}{2} \sum_{k=0}^{K-1} \|w^{k+1} - w^k\|_\sigma^2 + \frac{n\{1 - \kappa - \rho(\tau^{-1} + 12nL_1^2\tau)\}}{2} \sum_{k=0}^{K-1} \|\delta^{k+1} - \delta^k\|_\tau^2.
\]

All the coefficients for the quadratic terms in (40) are positive by the definition of \(\kappa\) (in Lemma 6) and the step-size conditions. Hence, we may remove the first four quadratic terms at the RHS of (40) to obtain

\[
\frac{1}{2}\|w^* - w^0\|_\sigma^2 + \frac{n}{2}\|\delta^* - \delta^0\|_\tau^2 - \frac{\rho L_1^2}{2} \frac{\|w^K - w^{-1}\|_\sigma^2 + \frac{\rho (6nL_1^2\tau)}{2} \|\delta^K - \delta^{-1}\|_\tau^2}{2} \\
+ \frac{(1 - 3\kappa - 3\rho(\sigma^{-1} + 4L_1^2\sigma))}{2} \sum_{k=0}^{K-1} \|w^{k+1} - w^k\|_\sigma^2 + \frac{n\{1 - \kappa - \rho(\tau^{-1} + 12nL_1^2\tau)\}}{2} \sum_{k=0}^{K-1} \|\delta^{k+1} - \delta^k\|_\tau^2.
\]

This proves that

\[
\frac{1}{K} \sum_{k=0}^{K-1} \|w^{k+1} - w^k\|^2 = O(1/K), \quad \frac{1}{K} \sum_{k=0}^{K-1} \|\delta^{k+1} - \delta^k\|^2 = O(1/K).
\]

By Lemma 8 and the definition of the saddle subdifferential norm,

\[
\|F(w^{k+1}, \delta^{k+1})\|^2 \leq 3(\sigma^{-1} + 2L_1^2\sigma)\|w^{k+1} - w^k\|_\sigma^2 + 6L_1^2\sigma\|w^k - w^{-1}\|_\sigma^2 + n(\tau^{-1} + 6nL_1^2\tau)\|\delta^{k+1} - \delta^k\|_\tau^2 + 6nL_2^2\tau\|\delta^k - \delta^{-1}\|_\tau^2.
\]

Averaging (43) over \(k = 0, \ldots, K - 1\) and using (42) concludes the proof.
Let \( \theta > 0 \). Hence, we may remove the last two quadratic terms at the RHS of (45) and take full

All the coefficients for the quadratic terms in (45) are non-negative by the definition of \( \kappa \) (in Lemma 6) and the step-size conditions. Hence, we may remove the last two quadratic terms at the RHS of (45) and take full
expectation to obtain
\[
\theta \mathbb{E} \langle w^* - w^k, \nabla_w \phi(w^k, \delta^k) - q^k \rangle + \frac{1}{2} \mathbb{E} \| w^* - w^k \|_{\sigma}^2 + \frac{n(1 + (n-1)\mu \tau/n)}{2} \mathbb{E} \| \delta^* - \delta^k \|_{\tau}^2
\]
\[+ \frac{\kappa \theta}{2} \mathbb{E} \| w^k - w^{k-1} \|_{\sigma}^2 + \frac{n \kappa \theta}{2} \mathbb{E} \| \delta^k - \delta^{k-1} \|_{\tau}^2
\]
\[\geq \mathbb{E} \langle w^* - w^{k+1}, \nabla_w \phi(w^{k+1}, \delta^{k+1}) - q^{k+1} \rangle + \frac{(1 + \mu \sigma)}{2} \mathbb{E} \| w^* - w^{k+1} \|_{\sigma}^2
\]
\[+ \frac{n(1 + \mu \tau)}{2} \mathbb{E} \| \delta^* - \delta^{k+1} \|_{\tau}^2 + \frac{\kappa}{2} \mathbb{E} \| w^{k+1} - w^k \|_{\sigma}^2 + \frac{n \kappa}{2} \mathbb{E} \| \delta^{k+1} - \delta^k \|_{\tau}^2.
\] (46)

Combining (46) and the definition of \(\theta\), we have
\[
\theta \left[ \mathbb{E} \langle w^* - w^k, \nabla_w \phi(w^k, \delta^k) - q^k \rangle + \frac{(1 + \mu \sigma)}{2} \mathbb{E} \| w^* - w^k \|_{\sigma}^2
\]
\[+ \frac{n(1 + \mu \tau)}{2} \mathbb{E} \| \delta^* - \delta^k \|_{\tau}^2 + \frac{\kappa}{2} \mathbb{E} \| w^k - w^{k-1} \|_{\sigma}^2 + \frac{n \kappa}{2} \mathbb{E} \| \delta^k - \delta^{k-1} \|_{\tau}^2 \right]
\[\geq \mathbb{E} \langle w^* - w^{k+1}, \nabla_w \phi(w^{k+1}, \delta^{k+1}) - q^{k+1} \rangle + \frac{(1 + \mu \sigma)}{2} \mathbb{E} \| w^* - w^{k+1} \|_{\sigma}^2
\]
\[+ \frac{n(1 + \mu \tau)}{2} \mathbb{E} \| \delta^* - \delta^{k+1} \|_{\tau}^2 + \frac{\kappa}{2} \mathbb{E} \| w^{k+1} - w^k \|_{\sigma}^2 + \frac{n \kappa}{2} \mathbb{E} \| \delta^{k+1} - \delta^k \|_{\tau}^2
\]
which, together with the fact that \((w^{-1}, \delta^{-1}) = (w^0, \delta^0)\), establishes
\[
\theta K \left[ \frac{(1 + \mu \sigma)}{2} \| w^* - w^0 \|_{\sigma}^2 + \frac{n(1 + \mu \tau)}{2} \| \delta^* - \delta^0 \|_{\tau}^2 \right]
\[\geq \mathbb{E} \langle w^* - w^K, \nabla_w \phi(w^K, \delta^K) - q^K \rangle + \frac{(1 + \mu \sigma)}{2} \mathbb{E} \| w^* - w^K \|_{\sigma}^2
\]
\[+ \frac{n(1 + \mu \tau)}{2} \mathbb{E} \| \delta^* - \delta^K \|_{\tau}^2 + \frac{\kappa}{2} \mathbb{E} \| w^K - w^{K-1} \|_{\sigma}^2 + \frac{n \kappa}{2} \mathbb{E} \| \delta^K - \delta^{K-1} \|_{\tau}^2
\]
\[\geq \frac{(1 + \mu \sigma - 2 \kappa)}{2} \mathbb{E} \| w^* - w^K \|_{\sigma}^2 + \frac{n(1 + \mu \tau)}{2} \mathbb{E} \| \delta^* - \delta^K \|_{\tau}^2.
\] (47)

where we have used (39) at the last inequality. By the definition of \(\kappa\) and the step-size conditions, all the coefficients for the quadratic terms at the RHS of (47) are positive. This concludes the proof. \(\square\)

B.5 Corollaries 3 and 4

Corollary 3. Suppose Assumptions 2 and 3 are true. Let \(\{w^k, \delta^k\}\) be the sequence generated by DSI-HG. If \(\theta = 1\) and \(\rho > 0\), \(\sigma > 0\), \(\tau > 0\) satisfy
\[
\max \{L_{12}(\sigma \tau)^{1/2}, L_{11} \sigma\} < \min \{1/3 - \rho(\sigma^{-1} + 4L_{11}^2 \sigma), 1 - \rho(\tau^{-1} + 12L_{12}^2 \tau)\},
\]
we have
\[
\frac{1}{K} \sum_{k=1}^{K} \| F(w^k, \delta^k) \|^2 = O(1/K).
\]

Corollary 4. Suppose Assumptions 2 and 3 are true. Let \(\{w^k, \delta^k\}\) be the sequence generated by DSI-HG. If \(\theta > 0\), \(\sigma > 0\), \(\tau > 0\) satisfy
\[
\max \{L_{12}(\sigma \tau)^{1/2}, L_{11} \sigma\} \leq 1/3, \quad \theta = \max \left\{ \frac{1}{1 + \mu \sigma}, \frac{1}{1 + \mu \tau} \right\},
\]
we have
\[
\| w^* - w^K \|^2 = O(\theta K), \quad \| \delta^* - \delta^K \|^2 = O(\theta K).
\]
C OMITTED EXPERIMENTS SETTINGS

All images are normalized into the range $[0, 1]$.

**YOPO.** For YOPO-$M$-$N$, we use $M = 10$ and $N = 5$. YOPO-5-10, which is compared with PGD-40 AT on MNIST in the paper for YOPO (Zhang et al., 2019a), performed worse than YOPO-10-5. Other than the learning rate schedule and $(M, N)$, we use the code and the exact hyperparameter choices released by the authors of YOPO.

**DAT.** For DAT training, maximum first-order stationary condition (FOSC) value is set to 0.5, and FOSC control epoch is set to 0.8 times the number of training epochs. Both are the parameter settings used by the authors of DAT (Wang et al., 2019).

**Other settings.** On SVHN and CIFAR-10, we use random horizontal flipping and random cropping augmentations. For MSI-HG, to promote exploration of the constraint set, we apply augmentation to $\delta$ as well. All other settings are described in Section 5.

| Dataset   | $\epsilon$ | $\tau$ | $T$ |
|-----------|------------|--------|-----|
| MNIST     | 0.4        | 0.2    | 5   |
| SVHN      | 4/255      | 6/255  | 10  |
| CIFAR-10  | 8/255      | 14/255 | 10  |

Table 5: Hyperparameter choices for MSI-HG in Section 5.
