Introduction

Migraine is a common disorder with a lifetime prevalence of 16%, worldwide, and a last-year prevalence of 10% [1, 2]. Although the pathogenesis of the migraine headache remains poorly understood, current theories suggest that a primary, genetically determined, central nervous system dysfunction is involved in the initiation of migraine headache, with subsequent activation of the trigeminovascular system [3, 4]. We review clinical and experimental evidence showing how nociceptive input from the cervical muscles may contribute to the activation of the trigeminovascular system as part of the pathogenesis of the migraine headache.

Pathogenesis of the migraine headache

Clinical and experimental considerations suggest that the pathogenesis of the migraine headache is intimately linked to the trigeminal innervation of the cranial blood vessels [5]. Dilation of these blood vessels and the consequent stimulation of the surrounding trigeminal sensory nerve fibres represent key mechanisms in the generation of the pain of the migraine headache [6]. Orthodromic conduction along the trigeminovascular nerve fibres transmits the nociceptive information centrally, via the trigeminal nucleus caudalis onto third-order neurones in the thalamus and from there on to cortical structures where the pain is perceived [7].
Central neuronal sensitisation

Sensitisation of central neurones is supposedly induced by input from the intracranial dura mater, travelling along the trigeminovascular pain pathway [8]. It results in:
(i) Reduction of the threshold to cell depolarisation;
(ii) Cellular activity that continues after cessation of the peripheral nociceptive input; and
(iii) Spread of cellular activity to neighbouring cells [9–11].

Noxious stimulation of muscle afferents increases the excitability of spinal cord neurones [12]. Persistent noxious stimulation leads to cellular and molecular changes, which result in neuronal hyperexcitability to the extent that pain is elicited by low-threshold, normally non-noxious stimuli [13–18]. Cells in the trigeminal nucleus caudalis that are normally nociceptive-specific begin to respond to low-threshold, primary afferent mechanoreceptors, after an increase in central excitability produced by the activation of peripheral chemoreceptors [19]. Repeated stimulation of a dorsal root produces, in some neurones, a prolonged heterosynaptic facilitation with an augmentation of the response to the conditioning root (homosynaptic potentiation) as well as to adjacent test roots (heterosynaptic potentiation) [20].

Nociceptive trigeminocervical convergence

The trigeminocervical nucleus is the area in the upper cervical spinal cord where sensory nerve fibres in the descending tract of the trigeminal nerve converge with sensory fibres from the upper cervical nerve roots [32]. In this nucleus, a considerable population of neurones demonstrates convergent input from the intracranial dura mater as well as from the cervical muscles. This convergence of trigeminal and upper-cervical nociceptive pathways suggests the existence of a functional continuum between the trigeminal and upper-cervical segments involved in cranial nociception and, thus, headache [33, 34]. Consequently, afferent nociceptive input from tight and sore or painful neck muscles innervated by the upper cervical nerve roots may contribute to the activation of the trigeminovascular, neuroinflammatory cascade [35].

The clinical phenomenon of pain in the front and back of the head and in the upper neck may be a consequence of overlapping processing of nociceptive information at the level of the second-order neurones in the trigeminocervical nucleus [34].

Conclusions

Current theories suggest that a primary, genetically determined, central nervous system dysfunction is involved in the initiation of the migraine headache, with subsequent activation of the trigeminovascular system and sensitisation of neurones in the central nervous system. Clinical findings suggest a relationship between migraine headache on the one hand and neck pain, or neck-muscle stiffness or tenderness, on the other hand. In addition, there is convergence of trigeminovascular and cervical-muscle nociceptive afferents in the area of the upper cervical cord, referred to as trigeminocervical nucleus. The evidence provides a compelling argument that central sensitisation may be enhanced, at least in some migraine patients, by sensory input originating from the cervical muscles.
