1. Introduction

In this paper we study the distribution of integral points of bounded height on toric varieties, i.e., quasi-projective algebraic varieties defined over number fields, equipped with an action of an algebraic torus $T$ and containing $T$ as an open dense orbit.

The case of projective compactifications has been the subject of intense study. It has been treated completely over number fields via \textit{adelic harmonic analysis} by Batyrev and the second author in a series of papers, see \textit{e.g.}, [2, 3, 4]. Subsequently, Salberger [33] and de la Bretèche [10] provided an alternative proof which relies on the parametrization of rational points by integral points on certain descent varieties called \textit{universal torsors}. These papers use a canonical height on toric varieties which reduces to the standard Weil height (maximum of absolute values of coordinates) in the case when $X$ is a projective space. Some other choices of heights have also been considered, at least for projective spaces, \textit{e.g.}, [35, 20]. Both methods, harmonic analysis and passage to universal torsors, have been applied in the function field case by Bourqui [8, 9].

These results were motivated by conjectures of Batyrev, Manin, Peyre and others concerning the asymptotic behavior of the number of points of bounded height in algebraic varieties over number fields [21, 1, 31, 5]. They stimulated the study of height zeta functions of equivariant compactifications of other algebraic groups and homogeneous spaces [37, 13, 36], as well as the study of universal torsors over Del Pezzo surfaces.

A related, classical, problem in number theory is the study of \textit{integral points} on algebraic varieties, for example complete intersections of low degree (circle method, [6]), algebraic groups or homogeneous spaces of semisimple groups (via ergodic theory or spectral methods, [17, 18, 19, 7]).

In this paper, as well as in [14], we apply the geometric and analytic framework proposed in [15] to “interpolate” between these two counting problems. Precisely, let $X$ be a smooth projective toric variety over a number field $F$, let $T$ be the underlying torus, and let $U \subseteq X$ be the complement of a $T$-stable divisor $D$ in $X$. We establish an asymptotic formula for the number of integral points of bounded height on $U$. The notion of integral points depends on the choice of a model of $U$ over the ring $\mathcal{O}_F$ of integers of $F$, while the normalization of the height is given by the log-anticanonical divisor $-(K_X + D)$ of the pair $(X, D)$; we assume that this log-anticanonical divisor belongs to the interior of the effective cone of $X$. In Theorem 3.11.5, we prove that

$$\frac{N(B)}{B(\log B)^{b-1}}$$

has a limit $\Theta$, when $B$ grows to infinity, where $b$ is some explicit positive integer described below.
We first need to recall two definitions from [15]. First (Definition 2.2), $\text{EP}(U\mathbb{F})$ is the virtual $\text{Gal}(\overline{F}/F)$-module given by

$$\left[H^0(U\mathbb{F}, \mathbb{G}_m)/\mathbb{F}^*\right]_\mathbb{Q} - \left[H^1(U\mathbb{F}, \mathbb{G}_m)\right]_\mathbb{Q}$$

and $r(\text{EP}(U))$, the dimension of the subspace of invariants under $\text{Gal}(\overline{F}/F)$, is given by

$$r(\text{EP}(U)) = \text{rank}(H^0(U, \mathbb{G}_m)/\mathbb{F}^*) - \text{rank}(\text{Pic}(U)).$$

Secondly (§3.1), for any place $v$ of $F$, the analytic Clemens complex $\mathcal{C}_v^{\text{an}}(D)$, is a simplicial complex which encodes the incidence properties of the $v$-adic manifolds given by the irreducible components of $D$. In this language, the integer $b$ is given by

$$b = r(\text{EP}(U)) + \sum_{v|\infty} (1 + \dim \mathcal{C}_v^{\text{an}}(D));$$

We also give a formula for the limit $\Theta$ (see Theorem 3.11.5). It involves the following analytic and geometric constants:

- volumes of adelic subsets with respect to suitable Tamagawa measures;
- local volumes (at archimedean places) of minimal strata of boundary components of $D$;
- characteristic functions of certain variants of the effective cones of $X$ attached to these strata and to the Picard group of $U$;
- orders of Galois cohomology groups.

This explicit formula shows that the constant $\Theta$ is positive provided that there are integral points in $\mathcal{U}$.

We also establish an equidistribution theorem for integral points of $U$ of bounded height.

He would also like to thank the Institute for Advanced Study in Princeton for its warm hospitality which permitted the completion of this paper. The second author was partially supported by NSF grants DMS-0739380 and 0901777. We thank Jean-Louis...
2. Toolbox

We now recall basic facts concerning algebraic tori, toric varieties, heights, and measures.

2.1. Algebraic numbers

Let $F$ be a number field. Let $\text{Val}(F)$ be the set of normalized absolute values of $F$. For $v \in \text{Val}(F)$, we write $|\cdot|_v$ for the corresponding absolute value, $F_v$ for the completion of $F$ at $v$. If $v$ is ultrametric, we also put $\mathfrak{o}_v$, $\mathfrak{w}_v$, $k_v$ for the ring of integers, a chosen local uniformizing element and the residue field at $v$, respectively; we write $p_v$ for the characteristic of the field $k_v$ and $q_v$ for its cardinality.

We normalize the Haar measure of a local field $E$ as in [38] (p. 310) so that the unit ball has measure
\[-2 \text{ if } E = \mathbb{R};\]
\[-2\pi \text{ if } E = \mathbb{C};\]
\[-|\text{disc}(E/\mathbb{Q}_p)|^{-1/2} \text{ if } E \text{ is a finite extension of } \mathbb{Q}_p.\]

We also define a real number $c_E$ by the following formula:
\[-c_\mathbb{R} = 2;\]
\[-c_\mathbb{C} = 2\pi;\]
\[-c_E = |\text{disc}(E/\mathbb{Q}_p)|^{-1/2}(1 - q^{-1})/\log(q)) \text{ if } E \text{ is a finite extension of } \mathbb{Q}_p \text{ and } q \text{ is the norm of a uniformizer.}\]

The ring of adeles of $F$ is the subspace $\mathbb{A}_F$ of the product ring $\prod_{v \in \text{Val}(F)} F_v$ consisting of families $(x_v)$ such that $x_v \in \mathfrak{o}_v$ for all but finitely many places $v$. If $S$ is a finite set of places of $F$, we write $\mathbb{A}_F^S$ for the similar subspace obtained by removing places in $S$. When $S$ is the set of archimedean places of $F$, we write $\mathbb{A}_F^{\text{fin}} = \mathbb{A}_F^S$ (finite adeles).

Let $E$ be a finite Galois extension of $F$ and let $\Gamma = \text{Gal}(E/F)$ be its Galois group. For any $v \in \text{Val}(F)$, we fix a decomposition group $\Gamma_v \subset \Gamma$ at $v$ and write $\Gamma_v^0$ for its inertia subgroup. If $v$ is finite, we fix a geometric Frobenius element $\text{Fr}_v \in \Gamma_v/\Gamma_v^0$.

Let $R$ be a ring, let $\overline{M}$ be an $R[\Gamma]$-module which is free of finite rank as an $R$-module. The Artin L-function of $\overline{M}$ is defined as the Euler product
\[L(s, \overline{M}) = \prod_{v \mid \infty} L_v(s, \overline{M}), \quad L_v(s, \overline{M}) = \det \left(1 - q_v^{-s} \text{Fr}_v \mid \overline{M}^{\Gamma_v^0}\right)^{-1}.\]

2.2. Algebraic tori

Let $T$ be an algebraic torus of dimension $d$ over $F$, i.e., an algebraic $F$-group scheme which becomes isomorphic to $\mathbb{G}_m^d$ over an extension of $F$. There exists a finite Galois extension $E$ of $F$ such that $T_E \simeq \mathbb{G}_m^d$; we fix such an extension and let $\Gamma$ be its Galois group.
A character of $T$ is a morphism of algebraic groups $T \to \mathbb{G}_m$; and a cocharacter a morphism of algebraic groups $\mathbb{G}_m \to T$. Let $\overline{M} = \mathrm{X}^\ast(T_E)$ be the group of $E$-rational characters of $T$, it is a torsion-free $\mathbb{Z}$-module of rank $d$ endowed with an action of $\Gamma$. The group $\overline{N}$ dual to $\overline{M}$ is the group of cocharacters of $T_E$.

The group $M = \overline{M}^\ast$ is the group of $F$-rational characters. The group $\overline{N}^\ast$ of $F$-rational cocharacters maps naturally into the space of coinvariants $N = \overline{N}_E$, which identifies with the dual of $M$. The map $\overline{N}^\ast \to N$ is not an isomorphism in general.

For any place $v \in \mathrm{Val}(F)$, we put

$$M_v = \begin{cases} \overline{M}_v^{\Gamma} & \text{for } v \nmid \infty \\ \overline{M}_v^\ast \otimes \mathbb{R} & \text{for } v | \infty \end{cases},$$

and define $N_v$ similarly. For $v | \infty$, the perfect duality between $\overline{M}$ and $\overline{N}$ induces a perfect duality $M_v \times N_v \to \mathbb{R}$. If $v$ is nonarchimedean, there is a natural bilinear map $M_v \times N_v \to \mathbb{Z}$ which, however, is not a perfect pairing in general.

For any nonarchimedean $v \in \mathrm{Val}(F)$, the bilinear map

$$T(F_v) \times M_v \to \mathbb{Z}, \quad (t, m) \mapsto -\log(|m(t)|)/\log(q_v)$$

induces a homomorphism $\log_v : T(F_v) \to N_v$ whose kernel $K_v$ is the maximal compact subgroup of $T(F_v)$ and whose image has finite index. Moreover, $\log_v$ is surjective for all ultrametric places $v$ which are unramified in the splitting field $E$ (see, e.g., [16, p. 449]). Similarly, for any archimedean $v \in \mathrm{Val}(F)$, the bilinear map

$$T(F_v) \times \overline{M}_v^{\Gamma} \to \mathbb{R}, \quad (t, m) \mapsto \log(|m(t)|)$$

induces a surjective homomorphism $\log_v : T(F_v) \to N_v$ whose kernel $K_v$ is the maximal compact subgroup of $T(F_v)$.

2.3. Description of the adelic group

Let $\mathbb{A}_F$ be the ring of adeles of $F$. The bilinear map

$$T(\mathbb{A}_F) \times M_\mathbb{R} \to \mathbb{R}, \quad ((t_v), m) \mapsto \sum_{v \in \mathrm{Val}(F)} \log(|m(t_v)|)$$

induces a surjective continuous morphism $T(\mathbb{A}_F) \to N_\mathbb{R}$. This morphism admits a section, e.g., given by $n \mapsto (t_v(n))$, where $t_v(n) = 1$ if $v$ is finite, $t_v(n) = \exp(n/[F:\mathbb{Q}])$ if $v$ is real, and $t_v(n) = \exp(2n/[F:\mathbb{Q}])$ if $v$ is complex.

Let $T(\mathbb{A}_F)^1$ be its kernel. By the product formula, $T(F)$ embeds as a discrete subgroup into $T(\mathbb{A}_F)^1$; moreover, the quotient $T(\mathbb{A}_F)^1/T(F)$ is compact. This induces a decomposition

$$T(\mathbb{A}_F)/T(F) \simeq N_\mathbb{R} \times (T(\mathbb{A}_F)^1/T(F))$$

of $T(\mathbb{A}_F)/T(F)$. The group $K_T = \prod_{v \in \mathrm{Val}(F)} K_v$ is the maximal compact subgroup of $T(\mathbb{A}_F)$; it is contained in $T(\mathbb{A}_F)^1$. 

INTEGRAL POINTS OF BOUNDED HEIGHT

5
Let $S \subset \text{Val}(F)$ be a finite subset containing the archimedean places. The map

$$T(\mathbb{A}_F) \to \prod_{v \in S} T(F_v) \to \prod_{v \in S} N_v$$

induces an isomorphism

$$T(\mathbb{A}_F)/T(F)K_T \simeq \prod_{v \in S} N_v/T(\mathfrak{o}_{F,S}),$$

where $T(\mathfrak{o}_{F,S}) = T(F) \cap \bigcap_{v \in S} K_v$. The map $T(\mathfrak{o}_{F,S}) \to \prod_{v \in S} N_v$ has finite kernel. Its image is a cocompact lattice in the subspace of $\prod_{v \in S} N_v$ consisting of tuples $(n_v)_{v \in S}$ such that $\sum_{v \in S} \langle m, n_v \rangle = 0$ for any $m \in M$.

### 2.4. Characters

Recall that the characters of a topological group $G$ are the continuous homomorphisms to the group $S^1$ of complex numbers of absolute value 1. They form a topological group $G^*$.

A character $\chi$ of $T(\mathbb{A}_F)$ is the product $(\chi_v)$ of its local components: for any $v \in \text{Val}(F)$, $\chi_v$ is a character of $T(F_v)$. A local character $\chi_v$ is called unramified if it is trivial on $K_v$; then there exists a unique element $m(\chi_v) \in M_v$ such that

$$\chi_v(t) = \exp(i \langle m(\chi_v), \log_v(t) \rangle), \quad \text{for all } t \in T(F_v).$$

A global character $\chi$ is called unramified if all of its local components are unramified, equivalently if it is trivial on $K_T$; it is called automorphic if it is trivial on $T(F)$.

The description of $T(\mathbb{A}_F)/T(F)K_T$ in Section 2.3 identifies an automorphic unramified character of $T(\mathbb{A}_F)$ as a character of $\prod_{v \in S} N_v/T(\mathfrak{o}_{F,S})$. Then, $(T(\mathbb{A}_F)/T(F)K_T)^*$ is the product of the continuous group $M_{\mathbb{R}}$ and the dual $\text{Hom}(T(\mathfrak{o}_{F,S}), \mathbb{Z})$ of the discrete group $T(\mathfrak{o}_{F,S})/\text{torsion}$.

### 2.5. Toric varieties

Let $X$ be a smooth projective equivariant compactification of $T$, i.e., a smooth projective variety $X$ over $F$ endowed with an action of $T$, and containing $T$ as a dense open orbit. The boundary divisor is the complementary closed subset $X \setminus T$; it is the opposite $-K_X$ of a canonical divisor.

By the general theory of toric varieties over algebraically closed fields, we may assume, extending $E$ if necessary, that the irreducible components of the boundary divisor $X_E \setminus T_E$ are smooth and geometrically irreducible, and that they meet transversally. Let $\mathcal{O}$ be the set of these irreducible boundary components. Since $X_E \setminus T_E$ is defined over $F$, the set $\mathcal{O}$ admits a natural action of the Galois group $\Gamma$, as well as of its subgroups $\Gamma_v$, for $v \in \text{Val}(F)$. We write $\mathcal{O}$, resp. $\mathcal{O}_v$ for the sets of orbits; the corresponding elements label $F$-irreducible, respectively $F_v$-irreducible, boundary components of $X \setminus T$.

For any $\alpha \in \mathcal{O}$, we write $F_\alpha$ for the subfield of $E$ fixed by the stabilizer of $D_\alpha$ in $\Gamma$, and $\Delta_\alpha$ for the sum of all irreducible components $D_{\alpha'}$, for $\alpha' \in \Gamma \alpha$. If $\alpha$ and $\alpha'$ belong to the same orbit, the fields $F_\alpha$ and $F_{\alpha'}$ are conjugate. For any finite place $v \in \text{Val}(F)$, the choice of a decomposition subgroup $\Gamma_v$ induces a specific place of $F_\alpha$, still denoted $v$, and we write $f_\alpha$ for the degree of $F_{\alpha,v}$ over $F_v$. 
The closed cone of effective divisors $\Lambda_{\text{eff}}(X_E) \subseteq \text{Pic}(X_E)_R$ on $X_E$ is spanned by the classes of boundary components $D_\alpha$, for $\alpha \in \mathcal{A}$. Similarly, the closed cone of effective divisors $\Lambda_{\text{eff}}(X) \subseteq \text{Pic}(X)_R$ on $X$ is spanned by the classes of the divisors $\Delta_\alpha$.

Viewing a character of $T_E$ as a rational function on $X_E$ and taking its divisor defines a canonical exact sequence of torsion-free $\Gamma$-modules

$$0 \to M \to \text{Pic}^T(X_E) \xrightarrow{\pi} \text{Pic}(X_E) \to 0,$$

where $\text{Pic}^T(X_E) \simeq \mathbb{Z}_{\mathcal{A}}^*$ is the group of equivalence classes of $T_E$-linearized line bundles on $X_E$. (Linearized line bundles are in canonical correspondence with $T_E$-invariant divisors in $X_E$, that is, linear combinations of boundary components.) The injectivity on the left follows from the fact that $X_E$ is normal and projective: if a character of $T_E$ has neither zeroes nor poles, then it is a regular invertible function on $X_E$, hence a constant. Taking Galois cohomology and using the fact that $\text{Pic}^T(X_E)$ is a permutation module, we obtain the following exact sequences:

$$0 \to M \to \text{Pic}^T(X) \to \text{Pic}(X) \to H^1(\Gamma, M) \to 0$$

$$0 \to M_v \to \text{Pic}^T(X_{F_v}) \to \text{Pic}(X_{F_v}) \to H^1(\Gamma_v, M) \to 0.$$

Moreover, the isomorphism $\text{Pic}^T(X_E) \simeq \mathbb{Z}_{\mathcal{A}}^*$ induces similar isomorphisms

$$\text{Pic}^T(X) \simeq \mathbb{Z}^g, \quad \text{Pic}^T(X_{F_v}) \simeq \mathbb{Z}^g_v.$$

By duality, the map $\mathcal{M} \to \mathbb{Z}^g$ gives rise to a morphism of tori $\prod_{\alpha \in \mathcal{A}} T_\alpha \to T$, where, for $\alpha \in \mathcal{A}$, $T_\alpha = \text{Res}_{F_\alpha/F}(\mathbb{G}_m)$ is the Weil restriction of scalars from $F_\alpha$ to $F$ of the multiplicative group. Using this morphism, any automorphic character $\chi \in (T(A_F)/T(F))^*$ induces an automorphic character of $T_\alpha(A_F)$, i.e., a Hecke character $\chi_\alpha$ of $F_\alpha$.

2.6. Quasi-projective toric varieties

Let $D$ be a reduced divisor in $X$ disjoint from $T$. The open set $U = X \setminus D$ is then a toric variety, non-projective for $D \neq \emptyset$. Let $\mathcal{A}_D \subset \mathcal{A}$ be the set of irreducible components of $D_E$ and $\mathcal{A}_D \setminus \mathcal{A}_U = \mathcal{A} \setminus \mathcal{A}_D$ be the complementary subset. The irreducible components of the divisor $U_E \setminus T_E$ are indexed by the traces on $U_E$ of the $D_\alpha$, for $\alpha \in \mathcal{A}_U$. The sets $\mathcal{A}_D$ and $\mathcal{A}_U$ are stable under the action of $\Gamma$; we let $\mathcal{A}_D$ and $\mathcal{A}_U$ be the sets of $\Gamma$-orbits (these are subsets of $\mathcal{A}$). There is a similar $\Gamma$-equivariant exact sequence

$$0 \to H^0(U_E, \mathcal{O}_U^*)/E^\times \to \mathcal{M} \to \mathbb{Z}^g \setminus \mathcal{A}_D \xrightarrow{\pi} \text{Pic}(U_E) \to 0.$$

Let $\rho = (\rho_\alpha)$ with $\rho_\alpha = 0$ if $\alpha \in \mathcal{A}_D$ and 1 otherwise. Throughout we shall assume that $\rho \in \Lambda^g(X)^\circ$, i.e., is contained in the interior of the image under $\pi$ of the simplicial cone $\mathcal{R}_{>0}$. In more geometric terms, this means that the line bundle $-(K_X + D)$ on $X$ is big; this includes the particular case where $(X, D)$ is log-Fano, i.e., $-(K_X + D)$ is ample.

2.7. Metrized line bundles and heights

Each boundary divisor $D_\alpha$, $\alpha \in \mathcal{A}$, defines a $T_E$-linearized line bundle on $X_E$. We fix smooth adelic metrics on these line bundles: by definition these are collections of metrics,
at all places \( w \) of \( E \), almost all of which come from a model of \( X_E \) defined over the ring of integers of \( E \); the smoothness condition means locally constant at finite places, and \( C^\infty \) at archimedean places. We assume that these metrics are invariant under the natural action the local Galois groups \( \Gamma_v \). We also assume that the metrics on a \( T \)-linearized line bundle only depend on the isomorphy class of the underlying line bundle.

For each \( \alpha \in \mathfrak{A} \), let \( f_\alpha \) be the canonical section of the line bundle \( \mathcal{O}(D_\alpha) \) with divisor \( D_\alpha \). Then the resulting height pairing is defined by

\[
H : T(\mathbb{A}_E) \times \text{Pic}^T(X_E)_{\mathbb{C}} \to \mathbb{C}^*, \quad ((x_w; \sum s_\alpha D_\alpha)) \mapsto \prod_{\alpha \in \mathfrak{A}} \prod_{w \in \text{Val}(E)} \|f_\alpha(x_w)\|^{s_\alpha/[E:F]}.
\]

It is \( \Gamma \)-equivariant, smooth in the first variable and linear in the second variable. (If \( s \in C^\infty \), we simply write \( H(x; s) \) for \( H(x; \sum s_\alpha D_\alpha) \).)

We shall also restrict the height pairing to line bundles defined over \( F \) and points in \( T(\mathbb{A}_F) \). This is compatible with a corresponding theory of adelic metrics over \( F \). Indeed, a component of \( X \setminus T \) decomposes over \( E \) as a sum of some divisors \( D_\alpha \) and this furnishes a canonical adelic metric on every line bundle on \( X \).

### 2.8. Volume forms and measures

Our analysis of the number of points of bounded height makes use of certain Radon measures on local analytic manifolds and on adelic spaces. Here we recall the main definitions, referring to [15] for a detailed account of the constructions of these measures in a general geometric context.

Let \( v \) be a place of \( F \). We fix a Haar measure on each completion \( F_v \) of \( F \), in such a way that \( \mu_v(\mathfrak{o}_v) = 1 \) for almost all finite places \( v \). Recall that the divisor on \( X \) of the invariant \( n \)-form \( dx \) on \( T \) (which is well-defined up to sign) is given by

\[
\text{div}(dx) = -\sum_{\alpha \in \mathfrak{A}} D_\alpha.
\]

We now define several measures on \( X(F_v) \). The first is a Haar measure for the torus \( T(F_v) \). It is defined “à la Weil” by

\[
\mu_{T,v} = |dx|_v,
\]

considering the invariant form \( dx \) as a gauge form on \( T \). Let \( \tau_v(T) = \mu_{T,v}(K_v) \) be the measure of the maximal compact subgroup \( K_v \) of \( T(F_v) \). If \( v \) is unramified in \( E \), then \( T \) has good reduction at \( v \) and

\[
\tau_v(T) = \#T(\mathfrak{o}_v)/q_v^{\dim T} = L_v(1, M)^{-1}
\]

(see [29], 3.3), where we extend \( T \) as a torus group scheme over \( \text{Spec}(\mathfrak{o}_v) \). We shall use the renormalized measure

\[
\mu_{T,v} = \tau_v(T)^{-1}|dx|_v.
\]

The local Peyre-Tamagawa measure on \( X(F_v) \) is defined by

\[
\mu_{X,v}' = |dx|_v / \|dx\|_v.
\]
Since $\text{Pic}(X_E)$ is a free $\mathbb{Z}$-module of finite rank, two other normalizations are possible:

$$\mu_{X,v} = L_v(1, \text{Pic}(X_E))^{-1} \mu_{X,v},$$
$$\mu_{U,v} = L_v(1, \text{EP}(U_F)) \mu_{U,v},$$

where $\text{EP}(U_F)$ is the virtual Galois module

$$\left[H^0(U_E, \mathcal{O}_X^*)/E^*\right] - \left[H^1(U_E, \mathcal{O}_X^*)/\text{torsion}\right].$$

With these normalizations, the products of local measures converge and define measures on suitable adelic spaces: $\prod_v \mu_{T,v}$ is a Haar measure on $T(\mathbb{A}_F)$, $\prod_v \mu_{X,v}$ and $\prod_v \mu_{U,v}$ are Radon measures on $X(\mathbb{A}_F)$ and $U(\mathbb{A}_F)$, respectively ([15], Theorem 2.5). For any finite $\mathcal{S} \subset \text{Val}(F)$, we define Radon measures on $T(\mathbb{A}_F^S)$, $X(\mathbb{A}_F^S)$, and $U(\mathbb{A}_F^S)$, by

$$\mu_T = L^S_v(1, T_v)^{-1} \prod_{v \notin \mathcal{S}} \mu_{T,v},$$
$$\mu_X = L^S_v(1, \text{Pic}(X_E)) \prod_{v \notin \mathcal{S}} \mu_{X,v},$$
$$\mu_U = L^S_v(1, \text{EP}(U_F))^{-1} \prod_{v \notin \mathcal{S}} \mu_{U,v},$$

where $L^S_v(1, \cdot)$ denotes the principal value of the Artin $L$-function at 1, with the finite Euler factors in $S$ removed.

In [15], we have also introduced residue measures which are Radon measures on $X(F_v)$ with support on $D(F_v)$. Recall that the $F_v$-analytic Clemens complex $\mathcal{E}_v^{\text{an}}(D)$ is a poset whose faces are pairs $(A, Z)$ where $A$ is a nonempty subset of $\mathcal{A}_v$ and $Z$ is an $F_v$-irreducible component of $D_A = \bigcap_{\alpha \in A} D_{\alpha}$ such that $Z(F_v) \neq \emptyset$. Its order relation is the one opposite to inclusion. (In the sequel, we shall often omit the irreducible component $Z$ from the notation.)

For each $\alpha \in \mathcal{A}_v$, we let $A_{F_{\alpha,v}}$ be the Weil restriction of scalars of the affine line from $F_{\alpha,v}$ to $F_v$; it is an affine space of dimension $[F_{\alpha,v} : F_v] = |\alpha|$. The norm map $N: F_{\alpha,v} \to F_v$ induces a polynomial function $N$ on $A_{F_{\alpha,v}}$ which defines the origin on the level of $F_v$-rational points. By abuse of notation, we write $dx_\alpha$ for the top differential form on $A_{F_{\alpha,v}}$ deduced from the one-form $dx$ on $A_1$.

Let $x \in X(F_v)$ and let $A_x$ be the set of $\alpha \in \mathcal{A}_v$ such that $x \in D_{\alpha}$. There exists a neighborhood $U_x$ of $x$ in $X(F_v)$ and a smooth map $(x_\alpha)_{\alpha \in A}: U_x \to \prod_{\alpha \in A} A_{F_{\alpha,v}}$ which defines $D_A(F_v)$ in a neighborhood of $x$.

Fix a pair $(A, Z)$ in $\mathcal{E}_v^{\text{an}}(D)$. The description above shows that $Z(F_v)$ is a smooth $v$-adic submanifold of $X(F_v)$ of codimension $\sum_{\alpha \in \mathcal{A}_v} |\alpha|$. Moreover, its canonical bundle admits a metric, defined inductively via the adjunction formula, in such a way that for any local top differential form $\omega$ on $Z(F_v)$,

$$||\omega|| = ||\tilde{\omega} \wedge \bigwedge_{\alpha \in A} dx_\alpha|| \prod_{\alpha \in \mathcal{A}_v} \lim_{x} \frac{||f_\alpha||}{|N(x_\alpha)|}.$$
where \( \tilde{\omega} \) is any local differential form on \( X(F_v) \) which extends \( \omega \). This gives rise to a measure \( \tau_{(A,Z)} \) on \( Z(F_v) \). As in [15], we normalize this measure further, multiplying it by the finite product \( \prod_{\alpha \in A} c_{F_{\alpha}} \) of constants defined as in Section 2.1.

3. Integral points

3.1. Setup

Let \( F \) be a number field, \( T \) an algebraic torus defined over \( F \), and \( X \) a smooth projective equivariant compactification of \( T \). Let \( D \) be a reduced effective divisor in \( X \setminus T \) and let \( U = X \setminus D \). We assume that the divisor \(- (K_X + D)\) on \( X \) is big.

Let \( \mathcal{U} \) be a fixed flat \( \mathfrak{o}_F \)-scheme of finite type with generic fiber \( U \). A rational point \( x \in T(F) \) will be called \( \mathfrak{o}_F \)-integral if there exists a section \( \varepsilon_x : \text{Spec}(\mathfrak{o}_F) \to \mathcal{U} \) which extends \( x \). Similarly, for any finite place \( v \in \text{Val}(F) \), a point \( x \in T(F_v) \) will be called \( \mathfrak{o}_v \)-integral if it extends to a section \( \text{Spec}(\mathfrak{o}_v) \to \mathcal{U} \). For any finite place \( v \), we write \( \delta_v \) for the set-theoretic characteristic function of the set of \( \mathfrak{o}_v \)-integral points in \( T(F_v) \). It is a locally constant function on \( T(F_v) \) whose support is relatively compact in \( U(F_v) \). For any archimedean place \( v \), we put \( \delta_v = 1 \) and write

\[
\delta = \prod_{v \in \text{Val}(F)} \delta_v.
\]

The generating Dirichlet series of integral points is called the height zeta function; it takes the form

\[
Z(s) = \sum_{x \in T(F) \cap \mathcal{U}(\mathfrak{o}_F)} H(x; s)^{-1} = \sum_{x \in T(F)} H(x; s)^{-1} \delta(x).
\]

This series converges absolutely and uniformly when all coordinates of \( s \) have a sufficiently large real part, and defines a holomorphic function in that domain. Formally, we have the Poisson formula

\[
Z(s) = \int \hat{H}(\chi; s) d\chi,
\]

where the integral is over the locally compact abelian group of characters of \( T(\mathbb{A}_F)/T(F) \) with respect to an appropriate Haar measure \( d\chi \), and

\[
\hat{H}(\chi; s) = \int_{T(k_F)} H(x; s)^{-1} \delta(x) \chi(x) d\mu_T(x)
\]

is the corresponding Fourier transform of the height function with respect to the fixed Haar measure \( d\mu_T \). As in the study of rational points in [2, 3, 4], we investigate the height zeta function by proving first that the Poisson formula applies; its right-hand-side provides a meromorphic continuation for the height zeta function. A Tauberian theorem will then imply an asymptotic expansion for the number of integral points of bounded height.

If \( V \) is a finite-dimensional real vector space and \( \Omega \) an open subset of \( V \), we write \( T(\Omega) = \Omega + iV \) for the tube domain of \( V_\mathbb{C} \) over \( \Omega \). If \( V \) has explicit coordinates \( (x_\alpha) \), we
shall also write $T_\delta$ for the tube domain over the open subset $\Omega_\delta$ defined by the inequalities $x_\alpha > \delta$.

### 3.2. Fourier transforms at finite places

**Lemma 3.2.1.** — For any finite place $v$ of $F$ and any character $\chi_v \in T(F_v)^*$ the local Fourier transform $\hat{H}_v(\chi_v; s)$ converges absolutely if $\text{Re}(s_\alpha) > 0$ for all $\alpha \not\in \mathcal{A}_v'$ and defines a holomorphic function of $s$ in the tube domain of $\mathbb{C}^d$ defined by these inequalities.

Moreover, there exists a compact open subgroup $K_v$ of $T(F_v)$, equal to the maximal compact subgroup for almost all $v$, such that $\hat{H}_v(\chi_v; s) = 0$ for any character $\chi_v$ which is nontrivial on $K_v$.

**Proof.** — The first part is a special case of our results concerning geometric Igusa functions ([15], Section 4.1). For the second, observe that we assumed the metrics to be locally constant at finite places, and the same holds for the characteristic function of the set of local integral points. As a consequence, there exists a compact open subgroup $K_v$ of $T(F_v)$ such that the height function $H_v(s; \cdot)$ is $K_v$-invariant. It follows that the Fourier transform vanishes at any character which is not trivial on $K_v$. Moreover, the adelic condition on the metrics, and the fact that the chosen integral model of the toric varieties $U$ and $X$ are toric schemes over a dense open subset of $\text{Spec}(\mathcal{O}_F)$, imply that for almost all $v$, one may take $K_v$ to be the maximal compact subgroup of $T(F_v)$.

**Lemma 3.2.2.** — For almost all finite places $v$, and all $s$ such that $\text{Re}(s_\alpha) > 0$ for all $\alpha \not\in \mathcal{A}_v'$, one has

$$\hat{H}_v(1; s) = \tau_v(T)^{-1}q_v^{-\dim X} \sum_{A \subseteq \mathcal{A}_U} \#D_A^\circ(k_v) \prod_{\alpha \in A} \frac{q_v^{f_{\alpha,v}} - 1}{q_v^{s_{\alpha} - 1} - 1}.$$  

**Proof.** — Let $\mathcal{X}$ be a flat projective $\mathcal{O}_F$-scheme with generic fiber $X$ and $\mathcal{D}$ the Zariski closure of $D$ in $\mathcal{X}$. There exists a finite set of places $S$ in $\text{Val}(F)$ such that, after restriction to $\mathcal{O}_{F,S}$, $\mathcal{X}$ is a smooth toric scheme, $\mathcal{X} \setminus \mathcal{D}$ is equal to $\mathcal{U}$, and all local metrics are defined by the given model.

For $v \not\in S$, one may compute $\hat{H}_v(1; s)$ using Denef’s formula. Using the good reduction hypothesis, the set of integral points in $T(F_v)$ is equal to $T(F_v) \cap \mathcal{U}(\mathcal{O}_v)$. Moreover, $U(\mathcal{O}_v) \cap (U \setminus T)(F_v)$ has measure zero with respect to the measure $\mu_{\mathcal{X},v}$. We thus can split the integral over the residue classes, introduce local coordinates, and write

$$\hat{H}_v(1; s) = \int_{T(F_v)} H_v(x; s)^{-1} \delta_v(x) d\mu_{T,v}(x)$$

$$= \tau_v(T)^{-1} \int_{\mathcal{U}(\mathcal{O}_v)} H_v(x; 1 - s) d\mu_{X,v}(x)$$

$$= \tau_v(T)^{-1} \sum_{A \subseteq \mathcal{A}_U} \#D_A^\circ(k_v) q_v^{\dim(X)} \prod_{\alpha \in A} \int_{m_{\alpha,v}} N_{\mathcal{O}_{F,v}/F_v}(x_\alpha)^{s_{\alpha} - 1} dx_\alpha$$

$$= \tau_v(T)^{-1} q_v^{-\dim X} \sum_{A \subseteq \mathcal{A}_U} \#D_A^\circ(k_v) \prod_{\alpha \in A} \frac{q_v^{f_{\alpha,v}} - 1}{q_v^{s_{\alpha} - 1} - 1}.$$
3.3. The product of local Fourier transforms at finite places

Let $K_{H,\text{fin}} = \prod_{v|\infty} K_v$ be the product of compact open subgroups given by Lemma 3.2.1 and $T(\mathbb{A}_F)^*_K \subset T(\mathbb{A}_F)^*$ the subgroup of characters whose restriction to $K_{H,\text{fin}}$ is trivial. Let $S$ be the finite set of those finite places $v$ such that either $K_v$ is distinct from the maximal compact subgroup of $T(F_v)$ or Lemma 3.2.2 fails for $v$.

For any character $\chi \in T(\mathbb{A}_F)^*_K$ and $s \in C^{\infty}$ such that $\Re(s_\alpha) > 0$ for $\alpha \notin \mathcal{A}_U$, define

$$\hat{H}_{\text{fin}}(\chi; s) = \prod_{v|\infty} \hat{H}_v(\chi_v; s) = \prod_{v|\infty} \int_{T(F_v)} H_v(x_v; s)^{-1} \delta_v(x_v) \chi_v(x_v) \, d\mu_{T,v}(x_v).$$

In this section, we study the convergence of this infinite product and its analytic properties with respect to $s$ and $\chi$.

Lemma 3.3.1. — Let $\Omega \subset \mathbb{R}^{\infty}$ be the open subset of all $s \in C^{\infty}$ such that $s_\alpha > 1/2$ for $\alpha \in \mathcal{A}_U$. The infinite product $\hat{H}_{\text{fin}}(\chi; s)$ converges whenever $\Re(s_\alpha) > 1$ for all $\alpha \in \mathcal{A}_U$ and extends to a meromorphic function of $s \in T(\Omega)$.

More precisely, for each $\chi \in T(\mathbb{A}_F)^*_K$, there exists a holomorphic function $\varphi(\chi; \cdot)$ on $T(\Omega)$ such that

$$\hat{H}_{\text{fin}}(\chi; s) = \varphi(\chi; s) \prod_{\alpha \in \mathcal{A}_U} L(s_\alpha, \chi_\alpha).$$

Moreover, for any positive real number $\varepsilon$, there exists $C(\varepsilon)$ such that $|\varphi(\chi; s)| \leq C(\varepsilon)$ for any character $\chi$ and any $s \in \Omega$ such that $\Re(s_\alpha) > \frac{1}{2} + \varepsilon$ for all $\alpha \in \mathcal{A}_U$.

(In that formula, $\chi_\alpha$ is the Hecke character of $F_\alpha$ deduced from $\chi$, as in Section 2.5.)

Proof. — This is a slight modification of the proof provided in [2], in the projective case. For any finite place $v \in \text{Val}(F)$, let us define a function $\varphi_v$ on $T(\Omega)$ by the formula

$$\hat{H}_v(\chi_v; s) = \varphi_v(\chi_v; s) \prod_{\alpha \in \mathcal{A}_U} L_v(s_\alpha, \chi_\alpha),$$

where $\chi_v$ is the local component at $v$ of a character $\chi \in T(\mathbb{A}_F)^*_K$.

For $v \notin S$, $\chi_v$ is unramified and hence takes the form

$$\chi_v(x) = H_v(x; -\text{im}(\chi_v)),$$

for some $m(\chi_v) \in M_v$, where we used the injection (2.5.3) to embed $M_v$ into $\mathbb{Z}^{\mathcal{A}_v}$. Consequently, for any such $v$, one has

$$\hat{H}_v(\chi_v; s) = \int_{T(F_v)} H_v(x; s)^{-1} \delta_v(x) \, d\mu_{T,v}(x)$$

$$= \int_{T(F_v)} H_v(x; s + \text{im}(\chi_v))^{-1} \delta_v(x) \, d\mu_{T,v}(x)$$

$$= \hat{H}_v(1; s + \text{im}(\chi_v)).$$

Observe that

$$L_v(s_\alpha, \chi_\alpha) = L_v(s_\alpha + \text{im}(\chi_\alpha), 1) = \zeta_{F_v}(s_\alpha + \text{im}(\chi_\alpha)).$$
Lemma 3.2.2 implies that \( \varphi_v \) is holomorphic on its domain. Moreover, for any positive real number \( \varepsilon \), there is an upper bound of the form

\[
|\varphi_v(\chi; \mathbf{s}) - 1| \ll q_v^{\min(1 + 2\varepsilon, 3/2)}
\]

for all \( \mathbf{s} \) such that \( \Re(s_{\alpha}) \geq \frac{1}{2} + \varepsilon \) for \( \alpha \in \mathcal{A}_v \).

For \( v \in S \), Lemma 3.2.1 implies that \( \hat{H}_v(\chi_v; \cdot) \) is holomorphic and uniformly bounded in this domain, independently of \( \chi \); the same holds for \( \hat{H}_v(\chi_v; \cdot) \).

These estimates imply the uniform and absolute convergence of the infinite product \( \prod \varphi_v(\chi_v; \cdot) \) on the tube domain \( T(\Omega) \); it defines a holomorphic function \( \varphi(\chi; \cdot) \) on this domain. Moreover, for any positive real number \( \varepsilon \), there exists a constant \( C(\varepsilon) \) such that

\[
|\varphi(\chi; \mathbf{s})| \ll C(\varepsilon)
\]

whenever \( \Re(s_{\alpha}) \geq \frac{1}{2} + \varepsilon \) for \( \alpha \in \mathcal{A}_v \).

Let \( \Omega_1 \) be the subset of \( \Omega \) defined by the inequalities \( s_{\alpha} > 1 \) for all \( \alpha \in \mathcal{A}_v \). Since Hecke L-functions converge when their parameter has real part > 1, the infinite product \( \hat{H}_{\text{fin}}(\chi; \mathbf{s}) \) converges absolutely on \( T(\Omega_1) \) and defines a holomorphic function on this tube domain such that

\[
\hat{H}_{\text{fin}}(\chi; \mathbf{s}) = \varphi(\chi; \mathbf{s}) \prod_{\alpha \in \mathcal{A}_v} L(s_{\alpha}, \chi_{\alpha}).
\]

This provides the asserted meromorphic continuation of \( \hat{H}_{\text{fin}} \).

**3.4. Fourier transforms at archimedean places**

To establish analytic properties of Fourier-transforms at archimedean places, we will extend the technique of geometric Igusa integrals developed in [15].

Fix an archimedean place \( v \) of \( F \). Since the \( F \)-rational divisors \( D_{\alpha} \) may decompose over \( F_v \), it is natural to consider the local height function \( H_v \) and its Fourier transform as functions of the complex parameter \( \mathbf{s} \in C^{\mathcal{A}_v} \). This generalization will in fact be required in the following sections.

Fix a splitting of the exact sequence

\[
0 \to T(F_v)^1 \to T(F_v) \to M_v \to 0.
\]

Each character of \( T(F_v) \) can now be viewed as a pair \( (\chi_1, m) \) of a character of the compact torus \( T(F_v)^1 \) and an element \( m \in M_v \). Similarly, for each \( \alpha \in \mathcal{A}_v \), let \( F_{\alpha,1} \) be the subgroup of \( F_{\alpha}^\times \) consisting of elements of absolute value 1. We decompose the field \( F_{\alpha}^\times = \mathbb{R}_+^\times \times F_{\alpha,1} \) and decompose the character \( \chi_{\alpha} \) accordingly, writing

\[
\chi_{\alpha}(x_{\alpha}) = |x_{\alpha}|^{-ima} \chi_{\alpha,1}(x_{\alpha}),
\]

where \( \chi_{\alpha,1} \) is a character of \( F_{\alpha,1} \).

**Lemma 3.4.1.** — Let \( v \) be an archimedean place of \( F \). Let \( \Omega_v \) be the open subset of \( \mathbb{R}^{\mathcal{A}_v} \) defined by the inequalities \( s_{\alpha} > -1/2 \) for all \( \alpha \in \mathcal{A}_v \). Then, for each face \( A \) of the
analytic Clemens complex $\mathcal{C}_{v}^{an}(D)$, there exists a function $\varphi_{v,A}(s, \chi_{v})$ holomorphic on the tube domain $T(\Omega_{v})$ of $\mathbb{C}^{d_{v}}$ such that

$$\hat{\mathcal{I}}_{v}(\chi_{v}; s) = \sum_{A \in \mathcal{E}_{v}^{an}(D)} \varphi_{v,A}(\chi_{v}; s) \prod_{\alpha \in A} \frac{1}{s_{\alpha} + \text{im}_{\alpha}}.$$ 

Moreover, each function $\varphi_{v,A}$ is rapidly decreasing in vertical strips; namely, for any positive real number $\kappa$, one has

$$|\varphi_{v,A}(\chi_{v}; s)| \ll (1 + \|\text{Im}(s)\| + \|m(\chi_{v})\| + \|\chi_{v,1}\|)^{-\kappa},$$

provided that $s \in T(\Omega_{v})$.

Assume that $s$ and $A$ are such that $s_{\alpha} = 0$ for $\alpha \in A$. If there exists an $\alpha \in A$ such that $\chi_{\alpha}$ is ramified, then $\varphi_{v,A}(\chi_{v}; s) = 0$.

Proof. — The proof is a variant of the analysis conducted in our paper [15]. Let us consider a partition of unity $(h_{A})$, indexed by the faces $A \subset \mathcal{A}_{v}$ of the analytic Clemens complex $\mathcal{C}_{v}^{an}(D)$ at $v$ such that the only divisors $D_{\alpha}$ which intersect the support of $h_{A}$ are those with index $\alpha \in A$. Up to refining this partition of unity, we also assume that on the support of $h_{A}$, there is a smooth map $(x_{\alpha})$ to $\prod_{\alpha \in A} F_{\alpha}$ such that for each $\alpha \in A$, $x_{\alpha} = 0$ is a local equation of $D_{\alpha}$. By the theory of toric varieties, we can moreover assume that the restriction of the map $x \mapsto x_{\alpha}$ to $T(F_{\alpha})$ is an algebraic character. Considering a complement torus, we obtain a system of local analytic coordinates $(x, y) = (x_{\alpha})_{\alpha \in A}, (y_{\beta})_{\beta \in B}$. In these coordinates, the character $\chi_{v}$ can be expressed as

$$\chi_{v}(x) = \prod_{\alpha \in A} \chi_{\alpha}(x_{\alpha}) \times \chi^{A}(y),$$

where $\chi^{A}$ is a character of $T(F_{\alpha})$.

After the corresponding change of variables, the integral, localized around the stratum $D_{A}(F_{v})$, takes the form

$$\mathcal{I}_{A}(\chi_{v}; s) = \int \prod_{\alpha \in A} \chi_{\alpha}(x_{\alpha}) |x_{\alpha}|^{s_{\alpha} - 1} \theta(s, x, y) \chi^{A}(y) dx dy,$$

where $\theta$ is a smooth function with compact support around the origin in $\prod_{\alpha \in A} F_{\alpha} \times F_{v}^{B}$. The local integral $\mathcal{I}_{A}$ takes the form

$$\mathcal{I}_{A}(\chi_{v}; s) = \int \prod_{\alpha \in A} |x_{\alpha}|^{s_{\alpha} + \text{im}_{\alpha} - 1} \left( \int \theta(s, x, y) \chi^{A}(y) \prod_{\alpha \in A} \chi_{\alpha,1}(x_{\alpha,1}) \prod_{\alpha \in A} dx_{\alpha,1} dy \right) \prod d |x_{\alpha}|.$$ 

In the inner integral, the variables $x_{\alpha,1}$ run over $F_{\alpha,1}$, i.e., $\{\pm 1\}$ or $S_{1}$, according to whether $F_{\alpha} = \mathbb{R}$ or $F_{\alpha} = \mathbb{C}$. In the latter case, we first perform integration by parts to establish the rapid decay of the inner integral with respect to the discrete part $\chi_{\alpha,1}$ of the character $\chi_{\alpha}$. Observe also that this inner integral tends to $0$ when $|x_{\alpha}| \to 0$ if the character $\chi_{\alpha,1}$ is nontrivial, i.e., the character $\chi_{\alpha}$ is unramified.
The stated meromorphic continuation can then be established, e.g., iteratively integrating by parts with respect to the variables \(|x_\alpha|\) and writing

\[ t^{s+im} = \frac{1}{s+im} \frac{\partial}{\partial t} \left( t^{s+im} \right). \]

This gives a formula as indicated, except for the rapid decay in \(s\). To obtain this, it suffices to perform integration by parts with respect to invariant vector fields in the definition of \(\hat{H}_v\). The point is that for any element \(d\) of \(\text{Lie}(T(F_v))\), there exists a vector field \(dX\) on \(X(F_v)\) whose restriction to \(T(F_v)\) is invariant; moreover, \(dX(H(x;s))H(x;s)^{-1}\) is a linear form in \(s\) times a regular function on \(X(F_v)\) (see [13], Proposition 2.2).

### 3.5. Integrating Fourier transforms

We now have to integrate the Fourier transform of the height function over the group of automorphic characters. For the analysis, it will be necessary to first enlarge the set of variables and then restrict to a suitable subspace. We thus consider a variant of the height zeta function depending on a variable \(\tilde{s} = (s, (s_v)_{v|\infty}) \in V_C\), where \(V\) is the real vector space

\[ V = \text{Pic}^T(X)_{\mathbb{R}} \oplus \bigoplus_{v|\infty} \text{Pic}^T(X_v)_{\mathbb{R}}. \]

For \(\tilde{s} \in V_C\) such that the series converges, we set:

\[ \tilde{Z}(\tilde{s}) = \sum_{x \in T(F) \cap \hat{W}(\sigma_F)} \prod_{v|\infty} H_v(x;s_v)^{-1} \times \prod_{v|\infty} H_v(x;s_v)^{-1}. \]

Formally, we again have the Poisson formula

\[ \tilde{Z}(\tilde{s}) = cT \int \hat{H}(\chi; \tilde{s})d\chi, \]

the integral over the locally compact abelian group of characters of \(T(\mathbb{A}_F)/T(F)\) with respect to a chosen Haar measure \(d\chi\) on \((T(\mathbb{A}_F)/T(F))^*\), here, for \(\tilde{s} = (s, (s_v))\),

\[ \hat{H}(\chi; \tilde{s}) = \hat{H}_\text{fin}(\chi; s) \prod_{v|\infty} \hat{H}_v(\chi_v; s_v) \]

is the corresponding Fourier transform of the height function. The constant \(c_T\) depends on the actual choice of measures, which we now make explicit.

Fix a section of the surjective homomorphism \(T(\mathbb{A}_F) \rightarrow M'_R\), whose kernel \(T(\mathbb{A}_F)^1\) contains \(T(F)\). If \(M'_R\) is endowed with the Lebesgue measure normalized by the lattice \(M'\), this gives rise to a Haar measure on \(T(\mathbb{A}_F)^1\). The section decomposes the group of automorphic characters as \(M'_R \oplus \mathbb{W}_T\). Let \(\mathbb{W}_T^K = T(\mathbb{A}_F)^1_K \cap \mathbb{W}_T\) be the subgroup of \(\mathbb{W}_T\) consisting of characters whose restriction to the compact open subgroup \(K_{H,\text{fin}}\) is trivial.

By Lemma 3.2.1 (see also the beginning of Section 3.3), the Fourier transform vanishes at any character \(\chi \in \mathbb{W}_T\) such that \(\chi \notin \mathbb{W}_T^K\). We normalize the Haar measure \(dm\) on \(M'_R\) by the lattice \(M\) and define a Haar measure on \((T(\mathbb{A}_F)/T(F))^*\) as the product of \(dm\) by
the counting measure on $\mathcal{W}_T$. Provided the expression in the right hand side converges absolutely, one can apply the Poisson summation formula and obtain

$$
\tilde{Z}(\tilde{s}) = \frac{c_T}{(2\pi)^{\text{rank } M}} \sum_{\chi \in \mathcal{W}_T^K} \int_{M_{\mathbb{R}}} \hat{H}(\chi; \tilde{s} + im) \, dm,
$$

with

$$
c_T = \text{vol}(T(A_F)^1/T(F))^{-1}.
$$

We work in the tube domain $T(\Omega_{\tilde{\rho}})$ of $V_C$ over the open subset $\Omega_{\tilde{\rho}}$ consisting of $\tilde{s} \in V$ satisfying the inequalities $s_\alpha > 1$ for $\alpha \in \mathcal{A}_U$ and $s_{v,\alpha} > 0$ for $\alpha \in \mathcal{A}_{D,v}$. Lemmas 3.3.1, 3.4.1, and the moderate growth of Hecke $L$-functions in vertical strips imply that the integrand decays rapidly, hence the validity of the Poisson formula. For any $\chi \in \mathcal{W}_T^K$ we set

$$
\tilde{Z}(\tilde{s}; \chi) = \frac{1}{(2\pi)^{\text{rank } M}} \int_{M_{\mathbb{R}}} \hat{H}(\chi; \tilde{s} + im) \, dm,
$$

so that

$$
\tilde{Z}(\tilde{s}) = c_T \sum_{\chi \in \mathcal{W}_T^K} \tilde{Z}(\tilde{s}; \chi).
$$

We first analyze individually the functions $\tilde{Z}(\chi; \tilde{s})$, for a fixed $\chi$. By Lemmas 3.4.1 and 3.3.1, one can write

$$
\hat{H}(\chi; \tilde{s}) = \varphi(\chi_{\text{fin}}; \tilde{s} + im) \prod_{\alpha \in \mathcal{A}_U} L(s_\alpha + im_\alpha; \chi_\alpha) \prod_{v|\infty \, A \in \mathcal{C}^\text{an,max}_v(D)} \sum_{\varphi_{v,A}(s_v + im + im(\chi_v))} \frac{\varphi_{v,A}(s_v + im + im(\chi_v))}{s_v + im + im(\chi_v)}.
$$

Let

$$
\mathcal{C}_v^{\text{an,max}}(D) = \prod_{v|\infty} \mathcal{C}_v^{\text{an,max}}(D).
$$

For any $A = (A_v) \in \mathcal{C}_v^{\text{an,max}}(D)$, set

$$
\hat{H}_A(\chi; \tilde{s}) = \varphi(\chi_{\text{fin}}; \tilde{s} + im) \prod_{\alpha \in \mathcal{A}_U} L(s_\alpha + im_\alpha; \chi_\alpha) \prod_{v|\infty \, A \in \mathcal{C}_v^{\text{an,max}}(D)} \sum_{\varphi_{v,A}(s_v + im(\chi_v); \chi_{v,1})} \frac{\varphi_{v,A}(s_v + im(\chi_v); \chi_{v,1})}{s_v + im(\chi_v)}
$$

so that

$$
\hat{H}(\chi; \tilde{s}) = \sum_{(A_v) \in \mathcal{C}_v^{\text{an,max}}(D)} \hat{H}_A(\chi; \tilde{s}).
$$

In turn, this decomposition of $\hat{H}$ induces a decomposition

$$
\tilde{Z}(\chi; \tilde{s}) = \sum_A \mathcal{C}_v^{\text{an,max}}(D) \tilde{Z}_A(\chi; \tilde{s}),
$$

where

$$
\tilde{Z}_A(\chi; \tilde{s}) = \frac{1}{(2\pi)^{\text{rank } M}} \int_{M_{\mathbb{R}}} \hat{H}_A(\chi; \tilde{s} + im) \, dm.
$$

We first analyse these series $\tilde{Z}_A$ separately.
For each $A \in \mathcal{C}_\infty^{an, \text{max}}(D)$, the function $\hat{H}_A(\chi; \tilde{s})$ is a meromorphic function on a tube domain, with poles given by affine linear forms whose vector parts are real and linearly independent. Now we apply a straightforward generalization of the integration theorem 3.1.14 from [11], where we only assume that the linear forms describing the poles are linearly independent, rather than a basis of the dual vector space. The convergence is guaranteed by the rapid decay of the functions $\varphi$ and $\varphi_{v, A_0}$ in vertical strips.

Let us set

$$\text{Pic}^T(U; A) = \text{Pic}^T(U) \oplus \bigoplus_{v|\infty} \mathbb{Z}^{A_v}.$$  

There is a natural homomorphism $M \to \text{Pic}^T(U; A)$ and we define $\text{Pic}(U; A)$ as the quotient $\text{Pic}^T(U; A)/M$.

**Lemma 3.5.1.** — The abelian group $\text{Pic}(U; A)$ is torsion-free.

*Proof.* — Let $D \in \text{Pic}^T(U)$ and, for any place $v$ such that $v | \infty$, let $D_v \in \mathbb{Z}^{A_v}$. Assume that the class of $(D, (D_v))$ modulo $M$ is torsion in $\text{Pic}(U; A)$. Let $n$ be a positive integer such that $n(D, (D_v))$ is the image of an element $m \in M$. We then have $nD = m$ in $\text{Pic}^T(U)$; since $\text{Pic}(U)$ is torsion-free ([22], p. 63), $D$ is the image of an element of $M$ by the natural map $M \to \text{Pic}^T(U)$.

This allows us to assume that $D = 0$.

For any archimedean place $v$, let $Z_v$ be any maximal stratum of $\mathcal{C}_v^{an}(X \setminus T)$ which contains $A_v$. Since $A_v$ is a maximal stratum of $\mathcal{C}_v^{an}(X \setminus U)$, the irreducible components of $(X \setminus T)_v$ which corresponds to elements of $Z_v \setminus A_v$ have to meet $U$. As a consequence, the divisor of the character $\chi_m$ is an $n$th power in the group of $T$-linearized divisors of the affine toric variety corresponding to $Z_v$. Using again [22], $\chi_m$ is an $n$th power on this toric variety. In particular, there exists an $m_v \in M$ such that $\chi_m = \chi_{m_v}^n$ as characters of $T$; in other words, $m' = m/n \in M_{\text{tor}}^{\text{tor}}$. In particular, $m' \in M$ and, since $m = nm' \in M^T$, we also have $m' \in M$. We have thus proved that $(D, (D_v))$ is the image of $m'$ by the natural map $M \to \text{Pic}^T(U; A)$, as was to be shown. \hfill \Box

Note that for $A = \emptyset$, one has $\text{Pic}^T(U; \emptyset) = \text{Pic}^T(U)$ but $\text{Pic}(U; \emptyset)$ is a sublattice in $\text{Pic}(U)$ of index $|H^1(\Gamma, \mathcal{M})|$. This discrepancy with the natural integral structure on $\text{Pic}(U)$ will appear later in the definition of the constant $\Theta$ below (compared with the definitions given in [2]).

Let $V_A$ be the real vector space $V_A = \text{Pic}^T(U; A)_{\mathbb{R}}$, endowed with the measure normalized by the lattice $\text{Pic}^T(U; A)$. We consider $V_A$ as a *quotient* of $V$ by letting $r_A: V \to V_A$ be the map which forgets the missing components. Let $\Lambda_A$ be the closed simplicial cone in $V_A$ consisting of all vectors $\tilde{s} = (s, (s_v))$ such that $s_\alpha \geq 0$ for all $\alpha \in \mathcal{A}_U$, and $s_{v, \alpha} \geq 0$ for all $v | \infty$ and $\alpha \in A_v$. Pulling-back via $r_A$ the characteristic function of $\Lambda_A$ we obtain a rational function $\mathcal{I}_{\Lambda_A}$ on $V_C$; it is given by

$$\mathcal{I}_{\Lambda_A}(\tilde{s}) = \left( \prod_{\alpha \in \mathcal{A}_U} s_\alpha \prod_{v | \infty} \prod_{\alpha \in A_v} s_{v, \alpha} \right)^{-1}.$$  

\hfill \Box
Set $V' = V/M$ and let $\pi: V \to V'$ be the natural projection. By Proposition 3.8.3 below, the composition $M_{\mathbb{R}} \to V \xrightarrow{\pi} V'$ is injective. Let $V'_A = V_A/M_{\mathbb{R}}$ and $\pi_A: V_A \to V'_A$ be the natural projection; one has $V'_A = \text{Pic}(U; A)_{\mathbb{R}}$; let us endow $V'_A$ with the Lebesgue measure normalized by $\text{Pic}(U; A)$. There exists a unique map $r'_A: V' \to V'_A$ such that $\pi_A \circ r'_A = r'_A \circ \pi$, so that $V'_A$ is a quotient of $V'$. We let $\Lambda'_A = \pi(\Lambda_A)$ be the image of $\Lambda_A$ in $V'_A$; it is an closed cone generated by the images of the generators of $\Lambda_A$. We pull-back to $V'$ the characteristic function of the cone $\Lambda'_A$ and obtain a rational function which is given by the integral formula

$$\mathcal{X}_{\Lambda_A}(\pi(\bar{s})) = \frac{1}{(2\pi)^{\text{rank} M}} \int_{M_{\mathbb{R}}} \mathcal{X}_{\Lambda_A}(\bar{s} + im) \, dm.$$

(See, e.g., [12], Proposition 3.1.9.)

We first conclude that for each $\chi \in \mathcal{H}_T^K$,

$$\tilde{Z}_A(\chi; \bar{s} + \bar{\rho} + i\tilde{m}(\chi)) = \frac{1}{(2\pi)^{\text{rank} M}} \int_{M_{\mathbb{R}}} \tilde{H}_A(\chi; \bar{s} + \bar{\rho} + i\tilde{m}(\chi) + im) \, dm,$$

so that the function

$$\bar{s} \mapsto \tilde{Z}_A(\chi; \bar{s} + \bar{\rho} + i\tilde{m}(\chi))$$

is holomorphic on the tube domain over the interior of the cone $(r'_A)^{-1}(\Lambda'_A)$ in $T(V')$. Moreover, there exists an open neighborhood $\Omega_A$ of the origin in $V'$ such that $\tilde{Z}_A(\chi; \bar{s} + \bar{\rho} + i\tilde{m}(\chi))$ extends to a meromorphic function on $T(\Omega_A + (r'_A)^{-1}(\Lambda'_A))$ whose poles are given by the linear forms on $V'$ corresponding to the faces of $\Lambda'_A$. Moreover, $\tilde{Z}_A$ decays rapidly in vertical strips and for any positive $\bar{s} \in V$,

$$(3.5.2) \quad \lim_{\ell \to 0} t^{\dim(\Lambda_A)} \tilde{Z}_A(\chi; ts + \rho + i\tilde{m}(\chi))$$

$$= \mathcal{X}_{\Lambda'_A}(\bar{s}) \varphi(\chi; \rho) \prod_{\alpha \in \partial\Omega} L^s(1; \chi_{\alpha}) \prod_{v \to \infty} \varphi_{v,A_v}(\chi_v, 1; im(\chi_v)).$$

We now sum these meromorphic functions $\tilde{Z}_A(\chi; \cdot)$ over all $\chi \in \mathcal{H}_T^K$. Due to the stated decay in vertical strips, this series converges and defines a meromorphic function with poles given by the translates of the cones $\Lambda'_A$ by a discrete subgroup consisting of (the images of) imaginary vectors $i\tilde{m}(\chi)$, for $\chi \in \mathcal{H}_T^K$.

**Lemma 3.5.3.** — Under the map $\chi \mapsto \pi(\tilde{m}(\chi))$, the group $\mathcal{H}_T^K$ is mapped to a discrete subgroup of $V'_A$.

**Proof.** — We first show that $\tilde{m}(\mathcal{H}_T^K)$ is discrete in $V_A$.

Let $v$ be an archimedean place of $F$. We proved in [15], Section 5.1, that each connected component of the analytic Clemens complex of a smooth toric variety is simplicial. Consequently, there exists a maximal stratum of $\mathcal{V}^{\text{an, max}}(X \setminus T)$ of the form $A_v \cup B_v$, where $B_v$ corresponds to divisors in $(U \setminus T)_v$. Let $N'_v$ and $N''_v$ be the subspaces of $N_v$ generated by the rays corresponding to the $F_v$-irreducible components of $(X \setminus T)_v$ occurring in $A_v$, resp. $B_v$. One has $N_v = N'_v \oplus N''_v$. Let us also set $N_\infty = \prod N_v$, and define similarly $N'_\infty$ and $N''_\infty$. 

Let $T' = \prod_{\alpha \in \mathcal{A}_D} G_{m,F_{\alpha}}$ and $T'' = \prod_{\alpha \in \mathcal{A}_U} G_{m,F_{\alpha}}$ be the quasi-split tori corresponding to $T$-linearized divisors in $D$, resp. outside $D$. The natural map $\overline{\mathcal{M}} \to \text{Pic}^T(X_E)$ of $\Gamma$-modules induces a surjective morphism of algebraic tori $T' \times T'' \to T$. Let $K'$ and $K''$ be compact subgroups of $T'(\mathbb{A}_F)$ and $T''(\mathbb{A}_F)$ such that $K' \times K''$ surjects onto $K$. Then, the map $(T(\mathbb{A}_F)/(T(F)K))^* \to M'_\infty$ "decomposes" as a product

$$(T'(\mathbb{A}_F)/(T'(F)K'))^* \times (T''(\mathbb{A}_F)/(T''(F)K''))^* \to M'_\infty \times M''_\infty.$$  

This identifies the image of $\mathfrak{U}_T^K$ in $\mathbb{A}(\mathbb{A})$ as the intersection with $M'_\infty$ of the lattice $\mathfrak{U}'_T^K \times \mathfrak{U}''_T^K$ in $M'_\infty \times M''_\infty$. It is therefore discrete, as claimed.

This description also shows that the image of $M_R$ in $\mathbb{A}(\mathbb{A})$ is orthogonal to $\tilde{m}(\mathfrak{U}_T^K)$. As a consequence, $\pi(\tilde{m}(\mathfrak{U}_T^K))$ is still discrete in $V'_\mathbb{A} = V_A/M_R$. 

This furnishes the existence and holomorphy of $\tilde{Z}$ in the tube domain over the open subset $\Omega_\rho$ of $\mathbb{A}$ formed of $\tilde{s} \in \mathbb{A}$ such that $\tilde{s} - \tilde{\rho}$ has positive coordinates. (Explicitly, these conditions mean that $s_\alpha > 1$ if $\alpha \in \mathcal{A}_D$, and that $s_v,\alpha > 0$ for all places $v | \infty$ and all $\alpha$ in a face of the analytic Clemens complex $\mathcal{C}^\text{an}_v(D)$.

### 3.6. Restriction to the log-anticanonical line bundle

Let us consider the particular case of the height zeta function with respect to the log-anticanonical line bundle. We assume that this line bundle belongs to the interior of the effective cone of $X$. Then there exists a $\lambda$ in the interior of the effective cone of Pic$^T(X)$ such that $\rho \sim \lambda$ in Pic($X$). Since the height of a rational point only depends on the isomorphism class of the underlying line bundle, one has

$$Z(s\rho) = Z(\rho + (s - 1)\lambda) = \tilde{Z}(\tilde{\rho} + (s - 1)\tilde{\lambda}),$$

where $\tilde{\lambda}$ is the vector $(\lambda, (\lambda)) \in V$. Observe that all components of $\tilde{\lambda}$ are positive. It follows that $s \mapsto Z(s\rho)$ is holomorphic for $\text{Re}(s) > 1$ and has a meromorphic continuation to the left of 1.

### 3.7. Poles on the boundary of the convergence domain

We now describe the poles of the function $s \mapsto Z(s\rho)$ which satisfy $\text{Re}(s) = 1$.

We first claim that they lie in a finite union of arithmetic progressions. Indeed, according to the summation process above, there is a pole at $1 + i\tau$ whenever there exists $\chi \in \mathfrak{U}_T^K$, $A = (A_v)$ a family of faces of maximal dimension of the analytic Clemens complexes, such that $r_A(\tau \lambda + \tilde{m}(\chi))$ belongs to a face of the cone $\Lambda_A$. This means that there exists $\alpha \in \mathcal{A}_v$ such that $\tau = -m_v(\chi_\alpha)/\lambda_\alpha$. The result now follows from the fact that for each fixed $(\alpha, v)$, the image of $\mathfrak{U}_T^K$ by the map $\chi \mapsto m_v(\chi_\alpha)$ is an arithmetic progression. Fix such a character $\chi \in \mathfrak{U}_T^K$ and $\tau \in \mathbb{R}$. According to the limit formula (3.5.2) and the vanishing of $\varphi_v$ for ramified characters stated in Lemma 3.4.1, the order of the pole at $1 + i\tau$ is at most equal to the sum $b(\tau)$ of the following integers:

- minus the rank of $M$;
- if $\tau = 0$, the cardinality of $\mathcal{A}_U$;
for each \( v | \infty \), the maximal cardinality of a face \( A_v \in \mathcal{C}^{an}(D) \) such that there exists an unramified character \( \chi_v \in \mathcal{U}_T \) such that for any \( \alpha \in A_v \), \( m(\chi_v, \alpha) = -\tau \).

We set \( b = b(0) \); observe that

\[
b = - \text{rank } M + |\mathcal{A}_U| + \sum_{v | \infty} (1 + \dim \mathcal{C}^{an}_v(D))
\]

since

\[
\text{rank } M - |\mathcal{A}_U| = \text{rank}(H^0(U, G_m)/F^*) - \text{rank}(\text{Pic}(U)) = r(\text{EP}(U)),
\]

the dimension of the \( \Gamma \)-invariants of \( \text{EP}(U) \). We shall prove later on, by computing the constant term, that the order of the pole at \( s = 0 \) is indeed equal to \( b \) (see Lemma 3.11.4).

Recall the assumption that the log-anticanonical divisor \( b \) belongs to the interior of the effective cone; a fortiori \( T \neq U \), hence \( \mathcal{A}_U \neq \emptyset \). Therefore,

\[
b > \sum_{v | \infty} (\dim \mathcal{C}^{an}_v(D) + 1) - \text{rank } M \geq b(\tau).
\]

### 3.8. Characters giving rise to the pole of maximal order

Let \( A(T)^* \) be the group of all automorphic characters \( \chi \in (T(\mathbb{A}_F)/T(F))^* \) such that \( \chi_\alpha \equiv 1 \) for all \( \alpha \in \mathcal{A} \).

**Lemma 3.8.1.** — The group \( A(T)^* \) is finite, and canonically identifies with the Pontryagin dual of the group \( T(\mathbb{A}_F)/T(F)^w \), quotient of \( T(\mathbb{A}_F) \) by the closure of \( T(F) \) for the product topology.

Note that the product topology on \( T(\mathbb{A}_F) \) is coarser than the adelic topology, so that \( T(F)^w \) is indeed a closed subgroup of \( T(\mathbb{A}_F) \).

**Proof.** — Let \( P \) be the quasi-split torus dual to the permutation Galois module \( \text{Pic}^T(X) \); the map \( M \to \text{Pic}^T(X) \) induces a morphism \( \mu: P \to T \) of algebraic tori. By definition, \( A(T)^* \) is the kernel of the morphism

\[
\mu^*: (T(\mathbb{A}_F)/T(F))^* \to (P(\mathbb{A}_F)/P(F))^*.
\]

By Pontryagin duality, \( A(T)^* \) is the dual of the cokernel of the map

\[
P(\mathbb{A}_F)/P(F) \to T(\mathbb{A}_F)/T(F)
\]

induced by \( \mu \). Inspection of the proof of Theorem 6 of [39] then shows this cokernel is equal to the finite group \( T(\mathbb{A}_F)/T(F)^w \), hence the lemma.

The quotient \( T(\mathbb{A}_F)/T(F)^w \) is classically denoted \( A(T) \), it measures the obstruction to weak approximation.

**Lemma 3.8.2.** — The closure \( \overline{T(F)} \) of \( T(F) \) in \( X(\mathbb{A}_F) \) coincides with \( X(\mathbb{A}_F)^{\text{Br}(X)} \), the locus in \( X(\mathbb{A}_F) \) where the Brauer–Manin obstruction vanishes. In particular, it is an non-empty open and closed subset of \( X(\mathbb{A}_F) \).
Proof. — Let us observe that $T(\mathbb{A}_F)$ is dense in $X(\mathbb{A}_F)$, so that $\overline{T(F)^w} = T(\mathbb{A}_F) \cap \overline{T(F)}$. According to [34], Theorem 8.12 and Corollary 9.4, $\overline{T(F)^w}$ coincides with the locus $T(\mathbb{A}_F)^{Br(X)}$ in $T(\mathbb{A}_F)$ where the Brauer–Manin obstruction vanishes. Observe that, $T(\mathbb{A}_F)^{Br(X)} = T(\mathbb{A}_F) \cap X(\mathbb{A}_F)^{Br(X)}$. Since the Brauer–Manin pairing is continuous and $Br(X)/Br(F)$ is finite, $X(\mathbb{A}_F)^{Br(X)}$ is open and closed in $X(\mathbb{A}_F)$. An easy topological argument then shows that $\overline{T(F)} = X(\mathbb{A}_F)^{Br(X)}$. □

A character $\chi \in \mathcal{M}_F^K$ contributes to a pole of order $b$ at $s = 0$ if and only if the following properties hold:
- for any $\alpha \in \mathcal{A}_U$, the Hecke character $\chi_{\alpha}$ is trivial;
- for any $v \mid \infty$, there exists a face $A_v$ of maximal dimension of $\mathcal{C}_v^{an}(D)$, such that for any $\alpha \in A_v$, the local character $\chi_{v, \alpha}$ is trivial.

Proposition 3.8.3. — Let $A = (A_v)_{v \mid \infty}$ be a family, where for each $v$, $A_v$ is a maximal stratum of $\mathcal{C}_v^{an}(D)$. Let $\chi \in T(\mathbb{A}_F)^*$ be any topological character satisfying the following assumptions:
- For all $\alpha \in \mathcal{A}_U$, the adelic character $\chi_{\alpha}$ is trivial;
- For any archimedean place $v$, the restriction of the analytic character $\chi_v$ to the stabilizer of the stratum $D_{A_v}$ in $T(F_v)$ is trivial.

Then all archimedean components of $\chi$ are trivial.

Proof. — We need to prove that for any archimedean place $v$, the analytic character $\chi_v$ is trivial. Let us fix such a place. The description of the analytic Clemens of a smooth toric variety done in [15] implies that for each $v$, there exists a maximal stratum $B_v$ of $\mathcal{C}_v^{an}(X \setminus T)$ containing $A_v$, and this stratum is reduced to a point $b_v \in X(F_v)$. Moreover, there exists a maximal split torus $T'_v$ in $T_{F_v}$ such that the Zariski closure of $T'_v$ in $X_{F_v}$ contains $b_v$. The assumptions imply that $\chi_{v, \beta}$ is trivial for any $\beta \in B_v$. Since the corresponding cocharacters generate the group of cocharacters of $T'_v$, the analytic character $\chi_v$ is trivial on $T'_v$. Moreover, the torus $T_{F_v}/T'_v$ is anisotropic by construction, so that $T(F_v)/T'_v(F_v)$ is compact; moreover, $T(F_v)$ is contained in the product of $T(F_v)$ and of the stabilizer in $T(F_v)$ of the stratum $D_{A_v}$. It follows that $\chi_v$ is trivial, as claimed. □

Definition 3.8.4. — Let $A(T, U)^*$ be the subgroup of $(T(\mathbb{A}_F)/T(F))^*$ consisting of characters $\chi$ such that:
- For all $\alpha \in \mathcal{A}_U$, the Hecke character $\chi_{\alpha}$ is trivial;
- For any $v \mid \infty$, the local character $\chi_v$ is trivial.

We also write $A(T, U, K)^*$ for the subgroup of $A(T, U)^*$ consisting of characters which are trivial on $K$.

According to Proposition 3.8.3, the characters which contribute to the main pole are elements of $A(T, U, K)^*$. We also see that the natural map $M_\mathbb{R} \to V_A$ is injective.

Lemma 3.8.5. — The group $A(T, U, K)^*$ is finite.

Proof. — Consider the natural morphism from $A(T, U, K)^*$ to $(K_T/K)^*$. Its image is finite. Since the archimedean components of the characters in $A(T, U, K)^*$ are trivial,
the kernel of this morphism is a subgroup of \((T(A_F)/T(F)T(F_\infty)K_T)^*\), hence is finite by Theorem 3.1.1 of [29].

Let \(M_U\) be the kernel of the natural map \(M \to \mathbb{Z}^{\text{dim} T}\) and let \(T_U\) be the corresponding torus. There is a surjective morphism of tori \(\pi: T \to T_U\) whose kernel is a torus \(T'\).

**Lemma 3.8.6.** — The orthogonal of \(A(T, U)^*\) in \(T(A_F)\) is a subgroup of finite index in \(\pi^{-1}(T_U(F))T(F_\infty)\).

**Proof.** — Let \(T(A_F)^\perp\) be the orthogonal of \(A(T, U)^*\). By definition of \(A(T, U)^*\), it contains \(T(F_\infty)T(F)\).

We have \(T'(A_F) \subset T(A_F)^\perp\). Indeed, let \(\chi \in A(T, U)^*\). For any place \(v\) of \(F\), the local component \(\chi_v\) of \(\chi\) is trivial on \(T'(F_v)\) because the Lie algebra of \(T'\) is orthogonal to \(M_U\), by definition of \(T'\). This implies that \(\chi\) is trivial on \(T'(A_F)\).

Furthermore, the exact sequence of cohomology

\[
T'(F) \to T(F) \to T_U(F) \to H^1(F, T'(F))
\]

implies that \(\pi(T(F))\) is a subgroup of finite index in \(T_U(F)\). The lemma follows.

Let \(T(A_F)^\perp\) be the orthogonal of \(A(T, U)^*\) in \(T(A_F)\). Since \(A(T, U, K)^*\) is the intersection of \(A(T, U)^*\) with the orthogonal of \(K\) in \(T(A_F)^*\), we have

\[
T(A_F)^{A(T, U, K)^*} = T(A_F)^\perp K.
\]

The left hand side is an open subgroup of finite index \(|A(T, U, K)^*|\) in \(T(A_F)\); we endow it with the Haar measure \(|A(T, U, K)^*|\mu_T\). Then, there exists a unique Haar measure \(\mu_T^\perp\) on \(T(A_F)^\perp\) such that for any \(K\)-invariant fonction \(f\) on \(T(A_F)\),

\[
\int_{T(A_F)^\perp} f(x) \, d\mu_T^\perp(x) = |A(T, U, K)^*| \int_{T(A_F)^{A(T, U, K)^*}} f(x) \, d\mu_T(x).
\]

This measure does not depend on the choice of the compact subgroup \(K\).

**3.9. The leading term**

By the preceding analysis, with \(b\) defined as in Equation (3.7.1), one has

\[
\lim_{t \to 1} (t - 1)^b Z(t \rho) = \sum_{A \in \mathcal{C}_{\infty}^{\text{an, max}}(D)} \Theta_A
\]

where, for each \(A \in \mathcal{C}_{\infty}^{\text{an, max}}(D)\),

\[
\Theta_A = c_T \sum_{\chi \in A(T, U, K)^*} \mathcal{X}_A^\prime (\pi(\lambda)) \varphi(\chi; \rho) \prod_{\alpha \in M_U} L^* (1; \chi_\alpha) \prod_{v \mid \infty} \varphi_v, A_v (\chi_v, 1; \text{im} (\chi_v))
\]

\[
= c_T \mathcal{X}_A^\prime (\pi(\lambda)) \left( \lim_{t \to 1} (t - 1)^{b+\text{rank} M} \left( \sum_{\chi \in A(T, U, K)^*} \hat{H}_A (\chi; \tilde{\rho} + (t - 1)\tilde{\lambda}) \right) \right).
\]

By Fourier inversion for the finite group \(A(T, U, K)^*\), we have

\[
\sum_{\chi \in A(T, U, K)^*} \hat{H}_A (\chi; \tilde{\rho} + (t - 1)\tilde{\lambda}) = |A(T, U, K)^*| \int_{T(A_F)^{A(T, U, K)^*}} H(x, \tilde{\rho} + \tilde{s}) \delta(x) \theta_A (x) \, d\mu_T(x).
\]
Moreover, since the functions we integrate are invariant under $K$, it follows from the definition (3.8.7) of the measure $\mu^\perp_T$ on $T(\mathbb{A}_F)^\perp$ that
\[
\sum_{\chi \in \mathcal{A}(\mathbb{A}_F)^\perp} \hat{H}_A(\chi; \hat{\rho} + (t - 1)\hat{\lambda}) = \int_{T(\mathbb{A}_F)^\perp} H(x; \hat{\rho} + \hat{s})\delta(x)\theta_A(x) \, d\mu^\perp_T(x),
\]
so that
\[
\Theta_A = c_T \mathcal{A}_{\mathbb{A}_F}^T(\pi(\hat{\lambda})) \times \left( \lim_{t \to 1}(t - 1)^{b + \text{rank } M} \int_{T(\mathbb{A}_F)^\perp} H(x; \rho + (t - 1)\lambda)\delta(x)\theta_A(x) \, d\mu^\perp_T(x) \right).
\]

### 3.10. Leading term and equidistribution for rational points

We assume in this Subsection that $U = X$, i.e., we consider the distribution of rational points of bounded height in toric varieties. In this case, all analytic Clemens complexes are empty and $\mathcal{C}_{\infty}^{\text{an, max}}(D)$ is understood as the set $\{\varnothing\}$. We have
\[
\text{Pic}(U; \varnothing) = \text{Pic}(X);
\]

because of the chosen normalizations for measures, and the characteristic function $\mathcal{A}_{\mathbb{A}_F}^T(X)$ is the characteristic function of the effective cone $\Lambda_{\text{eff}}(X)$ in $\text{Pic}(X)$ multiplied by $|H^1(\Gamma, \mathcal{M})|$. Moreover, $T(\mathbb{A}_F)^\perp$ is equal to $T(\mathbb{A}_F)^{\text{Br}(X)}$ and is endowed with the Haar measure $|A(T)^*|\mu_T$. The height zeta function has a single pole at $t = 1$ of multiplicity
\[
b = |\mathcal{A}| - \text{rank } M = \text{rank Pic}(X),
\]
and
\[
\Theta_{\varnothing} := \lim_{t \to 1}(t - 1)^b Z(t\rho)
\]
is given by
\[
(3.10.1) \quad \Theta_{\varnothing} = c_T |A(T)| |H^1(\Gamma, \mathcal{M})| \mathcal{A}_{\mathbb{A}_F}^T(\pi(\hat{\lambda})) \lim_{t \to 1}(t - 1)^{|\mathcal{A}|} \int_{T(\mathbb{A}_F)^{\text{Br}(X)}} H(x; t\rho) \, d\mu_T(x).
\]

The boundary of $T(\mathbb{A}_F)^{\text{Br}(X)}$ in $X(\mathbb{A}_F)$ is contained in a countable union of spaces of the form $\prod_{\mathcal{A} \neq \varnothing} X(F_\mathcal{A}) \times (X \setminus T)(F_\varnothing)$, hence has measure 0 for the Tamagawa measure $\tau_X$. In our paper [15], we have computed limits as the one appearing in (3.10.1) (Proposition 4.12) and derived in Theorem 4.13 an asymptotic formula for volumes, as well as the equidistribution property for height balls. This analysis implies that for any continuous function $\varphi$ on $X(\mathbb{A}_F)$,
\[
\lim_{t \to 1}(t - 1)^{|\mathcal{A}|} \int_{T(\mathbb{A}_F)^{\text{Br}(X)}} H(x; t\rho)\varphi(x) \, d\mu_T(x) = \prod_{\mathcal{A} \neq \varnothing} \frac{1}{\rho_\mathcal{A}} \int_{X(\mathbb{A}_F)^{\text{Br}(X)}} \varphi(x) \, d\tau_X(x),
\]
where $\tau_X$ is Peyre’s Tamagawa measure on $X(\mathbb{A}_F)$. Then, the same formula also holds for the characteristic function of $X(\mathbb{A}_F)^{\text{Br}(X)}$ since its boundary has measure 0. Therefore,
\[
\Theta_{\varnothing} = c_T |A(T)| |H^1(\Gamma, \mathcal{M})| \mathcal{A}_{\mathbb{A}_F}^T(\pi(\hat{\lambda})) \tau_X(X(\mathbb{A}_F)^{\text{Br}(X)}).
Lemma 3.10.2. — One has
\[ c_T |A(T)| |H^1(\Gamma, \mathcal{M})| = |H^1(\Gamma, \text{Pic}(X))|. \]

Proof. — The measure \( d\tau_{(X, X \setminus T)} \) is exactly the Haar measure of \( T(\mathbb{A}_F) \) used by Ono in [30]. According to this paper,
\[ \text{vol}(T(\mathbb{A}_F)^1 / T(F)) = \frac{|H^1(\Gamma, \mathcal{M})|}{|\mathcal{M}(T)|}. \]

Moreover, Voskresenskii has shown ([39], Theorem 6) that
\[ |A(T)| |\mathcal{M}(T)| = |H^1(\Gamma, \text{Pic}(X))|. \]

The lemma follows.

We summarize our results:

Theorem 3.10.3. — Let \( X \) be a smooth projective toric variety over a number field \( F \). Endow the canonical line bundle \( K_X \) with a smooth adelic metric and let \( H \) be the corresponding height function. Then the anticanonical height zeta function defined by
\[ Z(s) = \sum_{x \in T(F)} H_{K_X}(x)^s \]
is holomorphic for \( \text{Re}(s) > 1 \), has a meromorphic continuation to some half-plane \( \text{Re}(s) > 1 - \delta \) for some positive real number \( \delta \), with a single pole of order \( b = \text{rank} \text{Pic}(X) \) at \( s = 1 \) and has at most polynomial growth in vertical strips. Moreover,
\[ \Theta = \lim_{s \to 1} (s-1)^b Z(s) = |H^1(\Gamma, \text{Pic}(X))| \mathcal{B}_{\text{Ad}}(X)(\rho) \tau_X(X(\mathbb{A}_F)^{\text{Br}(X)}). \]

Corollary 3.10.4. — Under the hypothesis of Theorem 3.10.3, there exists a monic polynomial \( P \) of degree \( b - 1 \) and a positive real number \( \varepsilon \) such that one has
\[ \text{Card} \{ x \in T(F); H(x) \leq B \} = \frac{\Theta}{(b-1)!} BP(\log B) + O(B^{1-\varepsilon}), \quad B \to \infty. \]
Moreover, rational points of height \( \leq B \) equidistribute towards the probability measure
\[ \frac{1}{\tau_X(X(\mathbb{A}_F)^{\text{Br}(X)})} \tau_X|_{X(\mathbb{A}_F)^{\text{Br}(X)}} \]
on \( X(\mathbb{A}_F)^{\text{Br}(X)} \).

Since the Tamagawa measure has full support on \( X(\mathbb{A}_F) \), the equidistribution statement gives a quantitative refinement to the density of \( T(F) \) in \( X(\mathbb{A}_F)^{\text{Br}(X)} \) established in Lemma 3.8.2.

Proof. — The first statement follows the Theorem using a standard Tauberian theorem (see, e.g., Theorem A.1 of [15]). As already observed by Peyre in [31] (see also the abstract equidistribution theorem established in Proposition 2.10 of [15]), the second one is then a consequence of this formula, applied to any smooth adelic metric, combined with the fact that smooth adelic metrics are dense in the space of continuous adelic metrics.
3.11. Leading term and equidistribution for integral points

We return to the case of integral points. Recall that

\[
\lim_{t \to 1}(t-1)^b Z(t) = \sum_{A} \Theta_A
\]

where, for any \( A \in \mathcal{D}_{\infty}^{\text{an, max}}(D) \), \( \Theta_A \) is given by the formula

\[
\Theta_A = |A(T, U, K)^*| c_T \mathcal{Z}_A(\pi(\lambda)) \times \left( \lim_{t \to 1}(t-1)^{b+\text{rank} M} \int_{T(A_F)^{A(T, U, K)*}} H(x; \rho + (t-1)\lambda) \delta(x) \theta(x) \, d\mu_T(x) \right).
\]

Let us choose a family of representatives \((\xi_1, \ldots, \xi_m)\) for the finitely many cosets of \( T(A_F)^{A(T, U, K)*} \) in \( T(A_F) \). For any \( x \in T(A_F) \), let \( j(x) \) be the unique integer such that \( x \in \xi_{j(x)} T(A_F)^{A(T, U, K)*} \). We define a function \( \delta^\perp \) on \( T(A_F) \) by

\[
\delta^\perp(x) = \begin{cases} \delta(x) & \text{if } x \in T(A_F)^{A(T, U, K)*}; \\ 0 & \text{otherwise.} \end{cases}
\]

There exists a finite set \( S \) of finite places of \( F \) such that \( \xi_{j,v} \subseteq K_v \) for \( v \notin S \). Consequently, there exists a continuous function \( \delta^\perp_S \) on \( \prod_{v \in S} T(F_v) \) such that

\[
\delta^\perp(x) = \delta^\perp_S(x) \prod_{v \notin S} \delta_v(x_v).
\]

We now apply limit formulae from of our paper [15]. Indeed, a straightforward generalization of Equation (4.6) for the ring of finite adeles \( \mathcal{A}_F^S \), Proposition 4.6 for archimedean places, as well as the convergence statement of that proposition for places in \( S \), we obtain:

\[
\lim_{t \to 1}(t-1)^{b+\text{rank} M} \int_{T(A_F)^{A(T, U, K)*}} H(x; \rho + (t-1)\lambda) \delta(x) \theta(x) \, d\mu_T(x)
\]

\[
= \lim_{t \to 1}(t-1)^{b+\text{rank} M} \int_{T(A_F)} H(x; \rho + (t-1)\lambda) \delta(x) \theta(x) \, d\mu_T(x)
\]

\[
= \int_{\prod_{v \in S} T(F_v)} U(A_F^S) \prod_{v \in S} D_{A_v}(F_v) \prod_{v | \infty} d\tau_U^S(F_v) \prod_{v | \infty} d\tau_{A_v}(F_v),
\]

where the last integral is over

\[
\prod_{v \in S} T(F_v) U(A_F^S) \prod_{v | \infty} D_{A_v}(F_v).
\]

Recall that \( \theta_A \equiv 1 \) on \( \prod_{v | \infty} D_{A_v}(F_v) \). By definition of the measures \( \tau_U^S \) on \( U(A_F^S) \) and \( \tau_U^\text{fin} \) on \( U(A_F^\text{fin}) \), we thus have

\[
\lim_{t \to 1}(t-1)^{b+\text{rank} M} \int_{T(A_F)^{A(T, U, K)*}} H(x; \rho + (t-1)\lambda) \delta(x) \theta(x) \, d\mu_T(x)
\]

\[
= \int_{U(A_F^S)} \prod_{v | \infty} D_{A_v}(F_v) \delta^\perp_S(x) \prod_{v \notin S} \delta_v(x_v) \, d\tau_U^S(F_v) \prod_{v | \infty} d\tau_{A_v}(F_v).
\]
By Lemma 3.10.2,

\[ |A(T)|c_T = \frac{|H^1(\Gamma, \operatorname{Pic}(X))|}{|H^1(\Gamma, M)|} \]

so that,

\[ \Theta_A = \frac{|A(T, U, K)^*|}{|A(T)^*|} \frac{|H^1(\Gamma, \operatorname{Pic}(X))|}{|H^1(\Gamma, M)|} \mathcal{R}_{\Delta}^\wedge(\rho) \times \]

\[ \times \int_{U(\mathbb{A}_F^\wedge)} \prod_{v \mid \infty} D_{A_v}(F_v) \delta_{S}(x) \prod_{v \not\in S} \delta_v(x_v) d\tau_{U}^{\text{fin}}(x^{\text{fin}}) \prod_{v \mid \infty} d\tau_{A_v}(x_v). \]

In the case of rational points, the positivity of the constant \( \Theta_{\mathbb{Q}} \) was a straightforward consequence of the fact that \( X(\mathbb{A}_F)^{\text{Br}(X)} \) is open and non-empty in \( X(\mathbb{A}_F) \). For integral points, an additional argument is necessary. Indeed, the group \( A(T, U, K)^* \) may impose additional non-trivial obstructions to the existence of integral points.

**Definition 3.11.3.** — One says that \( \mathcal{U} \) possesses an automorphic obstruction to the existence of integral points if there does not exist a point \( (x_v) \in T(\mathbb{A}_F)^{\perp} \) such that \( x_v \in \mathcal{U}(\mathfrak{o}_v) \) for all finite places \( v \).

**Lemma 3.11.4.** — Assume that \( \mathcal{U} \) does not possess an automorphic obstruction to the existence of integral points. Then, for any \( A \in \mathcal{C}^{\text{an, max}}_\infty(D) \), one has \( \Theta_A > 0 \).

**Proof.** — Let \( \xi = (\xi_v) \) be any point in \( T(\mathbb{A}_F)^{\perp} \) such that \( \xi_v \in \mathcal{U}(\mathfrak{o}_v) \) for all finite places \( v \). Since all characters in \( A(T, U)^* \) are trivial on \( T(F_{\infty}) \), we may assume that \( \xi_v \in A_v \) for all archimedean places \( v \). The function

\[ x \mapsto \delta_{S}(x) \prod_{v \not\in S} \delta_v(x_v) \]

under the integral sign in the above limit formula is continuous and positive at this point \( \xi \). Since it belongs to the support of the measure \( d\tau_{U}^{\text{fin}}(x^{\text{fin}}) \prod_{v \mid \infty} d\tau_{A_v}(x_v) \), we obtain that \( \Theta_A > 0 \), as claimed. \( \square \)

Applying the tauberian theorem A.7 of [15], this concludes the proof of our main result concerning the number of integral points of bounded height:

**Theorem 3.11.5.** — Let \( X \) be a smooth projective toric variety over a number field \( F \). Let \( D \) be an invariant divisor such that \( -(K_X + D) \) is big and let \( U = X \setminus D \). Let \( \mathcal{U} \) be a model of \( U \) over \( \mathfrak{o}_F \). Assume that \( \mathcal{U} \) does not possess an automorphic obstruction to the existence of integral points. Let us endow the log-anticanonical line bundle \( -(K_X + D) \) with a smooth adelic metric; let \( H \) be the corresponding height function. Then, when \( B \to \infty \),

\[ \text{Card}\{x \in T(F) \cap \mathcal{U}(\mathfrak{o}_F) ; H(x) \leq B\} = \frac{\Theta}{(b - 1)!} B(\log B)^{b-1}(1 + O(1/\log B)), \]
where
\[ b = \text{rank} \text{Pic}(U) + \sum_{v|\infty} |A_v| = \text{rank} \text{Pic}(U) + \sum_{v|\infty} (1 + \dim \mathcal{C}_v^\text{an}(D)) \]

and \( \Theta \) is a positive real number given by
\[
\Theta = \frac{|A(T, U, K)^*|}{|T|^*} \cdot \frac{|H^1(\Gamma, \text{Pic}(X_E))|}{|H^1(\Gamma, M_E)|} \times \sum_{A \in E_{\text{max}}^\infty(D)} \mathcal{X}_A^\prime (\rho) \int_{U(A_F, \text{fin})} \prod_{D_{A_v}(F_v)} \delta^\perp(x) \text{d}r^\text{fin}_{U}(x_{\text{fin}}) \prod_{v|\infty} \text{d}r_{A_v}(x_v).
\]

Theorem 3.11.5 holds for any smooth metrization of the log-anticanonical line bundle. By the abstract equidistribution theorem of [15] (Prop. 2.10), we obtain the following corollary:

**Corollary 3.11.6.** — Retain the hypotheses of Theorem 3.11.5. Then, when \( B \to \infty \), the integral points of height \( \leq B \) equidistribute towards the unique probability measure on \( T(A_F)^+ \cap U(A_{F, \text{fin}}) \times \prod_{v|\infty} D_{A_v}(F_v) \) which is proportional to
\[
\sum_{A \in E_{\text{max}}^\infty(D)} \mathcal{X}_A^\prime (\rho) \int_{U(A_F, \text{fin})} \prod_{D_{A_v}(F_v)} 1_{X(A_F, \text{fin})} \delta^\perp(x) \text{d}r^\text{fin}_{U}(x_{\text{fin}}) \prod_{v|\infty} \text{d}r_{A_v}(x_v).
\]

**Remark 3.11.7.** — Langlands has parametrized the group of automorphic characters of an algebraic torus in terms of Galois cohomology of the dual L-group. This has been generalized by Kottwitz–Shelstad and Nyssen (see [28]) to complexes of tori. Comparing this description with the outcome of the Hochschild–Serre spectral sequence for the étale cohomology of \( G_m \) on \( U(\mathbb{R}) \) strongly suggests that the kernel of \( A(T, U)^* \) in \( T(A_F) \) is cut out by the Brauer–Manin obstruction defined by the algebraic part of \( \text{Br}(U) \). This holds indeed when \( U \) is proper (see [34] and Lemma 3.8.2 above) or when \( U = T \) (see [23]).
