ABSTRACT:

Aim: Farmers followed integrated farming but not on a commercial scale with heightened practices. However, local level characterization of different farming systems were analyzed on how adoption of farming systems and which remunerative components can improve their income levels, in turn their livelihood sustainability particularly, small and marginal farmers.

Methodology: Mahbubnagar, a rainfed district of the state was chosen to understand the characterization of farming systems under resource poor conditions. Multistage sampling technique was used. Herfindahl index was calculated for selection of mandals. Two mandals, four villages from each mandal and 15 farmers @ each village, total 120 farmers were selected.

Results: Four major farming systems Crop, Crop -Cattle, Crop - Cattle - Goat, Crop - Cattle – Sheep labelled as (FS-I, FS-II, FS-III and FS-IV) were identified in the study area. FS-IV (1.81) was the most remunerative farming system. Even across different farmer sizes, it was found best with the highest Benefit-Cost ratio (B-C) ratios. The highest adoption percent was for FS-II followed by I, III & IV. Results reveal that (36.67%) followed by -I, III, IV (20.83 %), (19.2 %), (9.17%) respectively.

Of the integrated farming systems, the highest remunerative component was Cattle for FS-II. (Cattle >Goat> Crop) is the declining order of the remunerative components for FS-III. (Sheep >Crop > Cattle) is the order for FS-IV. Across different size-classes of farmers (marginal, small and semi-medium), in all FS-I was found least remunerative. They showed consistent declining order of remunerative systems (FS-IV >-II > -III >-I) for marginal farmers, small farmers (FS-II > -III >-I) and semi-medium farmers (FS-IV >-II > -III >-I)

Conclusion: IFS reaped higher returns than only crop farming system. Livestock components added more weightage on income yielded in each farming system. Across all farmers’ classes, it is concluded that integration of different components enterprises increased the returns. Marginal and small farmers have better B-C ratios than semi-medium farmers in all farming systems.

Keywords: Integrated Farming Systems (IFS), Remunerative components, Remunerative farming system, Marginal, Small, Semi Medium farmers.

INTRODUCTION:

Farmers in India, followed subsistence farming in the past with mere cultivation of plants and domestication of animals. It was later shifted to traditional farming where they used traditional seeds, farm practices with low mechanised tools, machines and more human labour. It produced low surplus and was sufficient enough to carry out minimal trade for the contemporary situations.
However, the traditional farming and non-uniformity of resource endowments led agriculture flourish only in certain productive areas. So, country couldn’t cope up the drought and oversized population during 1965 - 1966 and caused the dearth of food. This led to the goal of self-sufficiency in food grain production. Green revolution ushered this and whole focus was on high yielding varieties to increase farm productivity and to reach self-sufficiency. This led to the commercialisation of agriculture.

Meanwhile, the focus of farmers shifted towards monocropping and are still reluctant towards diversified farming and integrating practices for the problems of price volatility, increased climatic aberrations, market disruptions and low-size farm holdings etc., Though IFS, is an age-old practice still farmers did not heighten the integration practices.

Integrated Farming Systems (IFS) is a multidisciplinary whole farm approach effective in addressing problems of small and marginal farmers by increasing income and employment by integrating various farm enterprises. It aims to improve the feasibility of small sized farming operations through integrated farming approach as compared with monoculture approaches.

As IFS aims at increasing productivity, profitability, food and nutritional security, sustainability, recycling of unutilised resources, generation of income round the year, increased employment generation. It appears to be the possible solution to the continuous increase of demand for food production, the stability of income and improvement of nutrition for the small and marginal farmers with limited resources.

There is potential for farmers to have a regular flow of income lifting them above the poverty line. There is convergence towards development of suitable location specific farm technology to raise and sustain the total farm productivity in terms of food, feed, fodder and fuel to meet the felt needs of the farming community. IFS is a powerful tool to enhance profitability, improve productivity and sustainability and is less risky when a well-designed system is adopted. No single farm enterprise, such as a typical mono-cropping system, is likely to be able to sustain the small-holder farmer. Integrated farming systems (IFS) are less risky if managed efficiently.

In this context, the study examines the major farming systems of the area, the remunerative components that make each Farming system viable. It also analyses remunerative farming systems for different farm classes

MATERIALS AND METHODS

Methodology: In Telangana state, Mahbubnagar district being one of the largest districts in terms of area (2737.96 sq.km) has a large number of small and marginal farmers with the low per capita availability of land. The share of land holdings of small and marginal farmers to the total
land holdings is more than three-fold (76.57 per cent) compared to other landholdings size categories of farmers.

Besides this, the district receives 749 mm of average annual rainfall with the highest drought frequency, the lowest share of irrigated area (19 per cent), lower productivity of major crops and low per-capita income (15380). All these factors make many of them resort to emigration to earn their living. In spite of all these, the district is endowed with rich livestock resources characterized by dairy animals, extensive sheep flock, etc., Thus, the potential to increase production and income in rainfed areas can be harnessed with Integrated Farming Systems (IFS) i.e., integrating both crop and livestock of the district.

The present study was undertaken to understand how farmers adopt different farming systems in the rainfed, drought-prone and poor resource endowment conditions. The map of the Mahbubnagar district is shown in Figure 1. In the district, Hanwada and Gandeed mandals were chosen for economic analysis. Herfindahl index was calculated and mandals were selected based on the values obtained. When the value of HI declines, crop diversification takes place and when value of HI increases, crop concentration takes place. Hanwada was selected as less diversified mandal which shows the value of 0.40 and Gandeed was selected as more diversified mandal which shows the value of 0.35.

Four villages from each mandal and @15 farmers from each village were selected randomly. The data was collected by personal interview with the aid of pre-tested schedules, from 120 farmers.

The data collected was analysed by working out simple averages, percentages and simple budgeting techniques.
Tabular analysis

Tabular analysis involving descriptive statistics like mean, frequency, percentages and simple budgeting techniques were employed to analyze the data and to ascertain the cropping pattern, livestock possession, costs and returns of the farmers and farming systems.

Index analysis

Index analysis was used to select the mandals of the district based on intensity of crop diversification. The crop diversification was measured using Herfindahl Index (HI) which is given by formula … (1)

\[ HI = \sum_{i=1}^{n} p_i^2 \ldots (1) \]

where, \( P_i \) is the proportion of area under the \( i^{th} \) crop. And \( P_i = A_i / \sum_{i=1}^{n} A_i \). And \( A_i \) is the actual area under \( i^{th} \) crop, and \( \sum_{i=1}^{n} A_i \) is the summation of area under all \( i \) crops and \( i = 1, 2, 3, \ldots, n. \)

When the value of HI declines, crop diversification takes place and when value of HI increases, crop concentration takes place.
**Returns:** The returns from all the enterprises were estimated at the actual price received by the farmer.

**Gross returns:** The total value of the main product and by-product was calculated as gross returns.

**Net returns:** Net returns were obtained by subtracting the total costs from gross returns.

**Returns per rupee spent/ Benefit-Cost ratio:** It is the returns realised per rupee spent on the enterprise.

It was calculated as gross returns to the total costs incurred.

Returns per rupee spent = gross returns / total cost.

---

**RESULTS AND DISCUSSION**

**Different farming systems adopted by farmers in the region**

The farmers of the study area practiced different farming systems. Based on the criteria of integration of different farm enterprises into the system, they were identified and characterized into ten different farming systems. The different farming systems adopted by farmers in the region are given in the Table.1.

Among the ten identified farming systems of the area, four of them were majorly adopted and they comprise of Crop, Crop - Cattle, Crop - Cattle - Goat, Crop - Cattle – Sheep labelled as FS-I, FS-II, FS-III and FS-IV. FS-II was highest adopted farming system by (36.67%) followed by FS-I (20.83 %), FS-III (19.2 %) and FS-IV (9.17%).

**Table 1: Different farming systems adopted by sample farmers of study area.**

| Farming systems | Crop | Crop-Cattle | Crop-Poultry | Crop-Cattle-Goat | Crop-Cattle-Goat-Sheep | Crop-Cattle-Goat-Poultry | Crop-Cattle-Goat-Poultry-Sheep | Total |
|----------------|------|-------------|--------------|------------------|------------------------|-------------------------|-------------------------------|-------|
| No. of farmers adopted | 25   | 44          | 4            | 2                | 4                      | 23                      | 11                                           | 120   |
| Percent of adoption    | 20.8 | 36.67       | 3.33         | 1.67             | 3.33                   | 19.2                    | 9.17                                         | 100   |
The details of cropping pattern of farmers in different farming system Table 2. reveal the major crops as paddy, jowar, red gram, groundnut and maize. Other crops grown were, castor, cotton, fodder, onion, millets and vegetables.

Livestock possession of different farming systems was detailed in Table 3. Of all non-crop farm enterprises, cattle was the most integrated one in the systems.

| 12    | Onion        | 0.15                    | 2.41          | -                        | -             | 0.57                     | 2.01          | 0.13                     | 1.32          |

Table 3. The average size of the Cattle, Goat, Sheep of the major integrated farming systems.

| S. No | Major Farming Systems | CROP in ac. | CATTLE Avg. size (in no.) | GOAT Avg. size (in no.) | SHEEP Avg. size (in no.) |
|-------|-----------------------|-------------|---------------------------|-------------------------|--------------------------|
|       |                       |             |                           |                         |                          |
Component wise total costs and returns of major farming systems.

In FS-I, the total per farm costs, gross returns, net returns, B-C ratio were ₹ 144784.1, ₹232192.6, ₹88162, 1.60 respectively with average acreage of 4.35 acres.

In FS-II, the total farm costs, gross returns, net returns, B-C ratio of the entire farming system were ₹363975, ₹650542, ₹276903, 1.77 respectively. The component wise analysis indicates higher net returns for crop component, but B-C ratio was highest for Cattle.

In FS-III, the total per farm costs, gross returns, net returns, B-C ratio of the entire farming system were ₹255386, ₹455710, ₹200324, 1.75 respectively. Among all the components of FS-III, B-C ratio was observed to be highest for Cattle (1.94) followed by Goat (1.60) and Crop (1.56).

In FS-IV, the total per farm costs, gross returns, net returns, B-C ratio of the entire farming system were ₹331340.17, ₹598641.67, ₹267301, 1.81 respectively. Among all the components of FS-IV, B-C ratio was observed to be highest for sheep (2.41) followed by crop (1.56) and cattle (1.53). The Component wise total costs and returns of identified major farming systems are given in Table 4.

Table 4. Component wise total costs and returns of identified major farming systems.

| Component | Average Area (ac)/ No | Total costs (Rs.) | Gross returns (Rs.) | Net returns (Rs.) | Benefit - cost ratio |
|-----------|-----------------------|-------------------|---------------------|------------------|---------------------|
| FS-I      |                       |                   |                     |                  |                     |
| Crop      | 4.35                  | 144784            | 32192.6             | 88161.2          | 1.6                 |
| FS-II     |                       |                   |                     |                  |                     |
| Crop      | 5.91                  | 293687            | 521130              | 227538           | 1.78                |
| Cattle    | 4.84                  | 115329            | 228778              | 113449           | 2                   |
| Total     | -                     | 363975            | 650542              | 276903           | 1.77                |
| FS-III    |                       |                   |                     |                  |                     |
| Crop      | 4.6                   | 103101            | 163389              | 60288            | 1.56                |
| Cattle    | 5.43                  | 102836            | 208243              | 105407           | 1.94                |
| Goat      | 25.56                 | 49448.7           | 84078.3             | 34629.6          | 1.6                 |
| Total     |                       | 243856            | 395710              | 199036           | 1.75                |
| FS-IV     |                       |                   |                     |                  |                     |
Analysis of the majorly adopted farming system reveals FS-IV as more remunerative with highest total benefit-cost ratio of 1.81. FS-II, FS-III and FS-I follows in order with 1.77, 1.75 and 1.60 as returns per rupee spent respectively. This implies IFS reaps higher returns than only crop farming systems. Sivamuruga et al. (2008) reported that integration of cropping along with other enterprises gave higher economic returns than the cultivation of crops alone (5).

Of the integrated farming systems, the highest remunerative component was Cattle for FS-II. (Cattle > Goat > Crop) is the declining order of the remunerative components for FS-III. (Sheep > Crop > Cattle) is the order for FS-IV. It implies livestock components added more weight to the income yielded by each farming systems. The contribution to the farm income by the crop decreases with the increase in integration.

It was observed that the B-C ratios did not vary much among integrated farming systems indicating that as net returns increased, simultaneously costs also increased with the integration of other enterprises. (Manjunatha et al. (2014) (6)

**Economic analysis of farming systems for different size group farmers.**

For marginal farmers, the returns per rupee spent was highest for FS-IV (2.01) followed by FS-II (1.81), FS-III (1.75) and FS-I (1.6). For small farmers, declining order of remunerative systems was (FS-II > -III > -I) with the B-C ratios 1.94, 1.65 and 1.62 respectively. For semi-medium farmers, FS-IV (1.8) yielded better income followed FS-II (1.69), FS-III (1.65) and FS-I (1.58).

Across different size-classes of farmers (marginal, small and semi-medium), in all FS-I was found least remunerative. Despite the sizes of farmers’ classes, it is concluded integration of the enterprises, increased the returns of each farming system.

It can be concluded that in all the four major identified farming systems, the B-C ratios were observed to be higher for marginal and small farmers than semi-medium farmers. Sen et al. (2017) from their study reveals that marginal farms had considerably higher per hectare farm income than small and medium farmers (7)

**Table 5. Economics of marginal, mall and semi-medium farmers adopting major Farming Systems.**

|          | Crop  | Cattle | Sheep | Total |
|----------|-------|--------|-------|-------|
|          | 5.96  | 124260 | 192275| 68014.8|
| Cattle   | 3.66  | 117497 | 177117| 59620 |
| Sheep    | 88.33 | 89583.3| 229250| 139667|
| Total    | 291990| 544622 | 224906| 1.81  |
CONCLUSIONS:

Among the ten identified farming systems of the area, four of them were majorly adopted and they comprise of Crop, Crop-Cattle, Crop-Cattle-Goat, Crop-Cattle-Sheep labelled as FS-I, FS-II, FS-III and FS-IV. FS-II was highest adopted farming systems by (36.67%) followed by FS-I (20.83%), FS-III (19.20%) and FS-IV (9.17%).

Analysis of the majorly adopted farming system reveals FS-IV as more remunerative with highest total benefit-cost ratio of 1.81. FS-II, FS-III and FS-I follows in order with 1.77, 1.75 and 1.60 as returns per rupee spent respectively. This implies IFS reaps higher returns than only crop farming systems.

Of the integrated farming systems, the highest remunerative component was Cattle for FS-II. (Cattle > Goat > Crop) is the declining order of the remunerative components for FS-III. (Sheep > Crop > Cattle) is the order for FS-IV. It implies livestock components added more weight to the income yielded by each farming systems. However, The B-C ratios did not vary much among different farming systems indicating that as net returns increased, simultaneously costs also increased with the integration of other enterprises.

Across different size-classes of farmers (marginal, small and semi-medium), in all FS-I was found least remunerative. They showed consistent declining order of remunerative systems (FS-IV

| Farming systems | No. of farmers | Avg. Area (in ac) | Cattle (No’s) | Goat (No’s) | Sheep (No’s) | Total Costs (Rs) | Gross Returns (Rs) | Net Returns (Rs) | Benefit -Cost Ratio |
|-----------------|----------------|------------------|--------------|------------|-------------|------------------|-------------------|------------------|-------------------|
| Marginal farmers |                |                  |              |            |             |                  |                   |                  |                   |

UNDER PEER REVIEW
>-II > -III >-I) for marginal farmers, small farmers (FS-II > -III >-I) and semi-medium farmers (FS-IV >-II > -III >-I) indicating Crop - Cattle – Sheep yielded better income followed Crop – Cattle and Crop - Cattle – Goat. Despite the sizes of farmers’ classes, it is concluded integration of the enterprises, increased the returns of each farming system. In all farming systems, B-C ratios were observed to be higher for marginal and small farmers than semi-medium farmers.
