Paracoccidioidomycosis (PCM), a common chronic mycosis in Latin America, is a granulomatous systemic disease caused by the thermo-dimorphic fungus Paracoccidioides brasiliensis. The glycoprotein gp43 is the main antigen target of P. brasiliensis and a 15-mer internal peptide (QTLIAIHTLAIRYAN), known as P10, defines a major CD4+-specific T cell epitope. Previous results have indicated that, besides having a preventive role in conventional immunizations prior to challenge with the fungus, protective anti-fungal effects can be induced in P. brasiliensis-infected mice treated with P10 administered with complete Freund’s adjuvant (CFA). The peptide elicits an IFN-γ-dependent Th1 immune response and is the main candidate for effective immunotherapy of patients with PCM, as an adjunctive approach to conventional chemotherapy. In the present study we tested the therapeutic effects of P10 combined with different adjuvants [aluminum hydroxide, complete Freund’s adjuvant (CFA), flagellin, and the cationic lipid dioctadecyl-dimethylammonium bromide (DODAB)] in BALB/c mice previously infected with the P. brasiliensis Pb18 strain. Significant reductions in the number of colony forming units of the fungus were detected in lungs of mice immunized with P10 associated with the different adjuvants 52 days after infection. Mice treated with DODAB and P10, followed by mice treated with P10 and flagellin, showed the most prominent effects as demonstrated by the lowest numbers of viable yeast cells as well as reductions in granuloma formation and fibrosis. Concomitantly, secretion of IFN-γ and TNF-α, in contrast to interleukin (IL)-4 and IL-10, was enhanced in the lungs of mice immunized with P10 in combination with the tested adjuvants, with the best results observed in mice treated with P10 and DODAB. In conclusion, the present results demonstrate that the co-administration of the synthetic P10 peptide with several adjuvants, particularly DODAB, have significant therapeutic effects in experimental PCM.

INTRODUCTION

Paracoccidioidomycosis (PCM) is a systemic mycosis that typically starts as a granulomatous pulmonary disease subsequent to the inhalation of conidia of the dimorphic fungus Paracoccidioides brasiliensis. When it is not diagnosed and treated properly, P. brasiliensis yeast cells can spread rapidly to lymph nodes, tegument, spleen, liver, and lymphoid organs of the digestive tract (Shikanai-Yasuda et al., 2006). PCM is endemic in Latin America, mostly affecting rural workers in Brazil, Colombia, and Venezuela (Wanke and Londero, 1994), and the majorities are involved in agricultural activities (Blotta et al., 1999; Restrepo et al., 2008). In Brazil, approximately 1,853 (∼51.2%) of 3,583 confirmed deaths due to systemic mycoses from 1996 to 2006 were caused by PCM (Prado et al., 2009). gp43 is a glycoprotein of 416 amino acids (Puccia et al., 1986; Cisalpino et al., 1996). A specific T-CD4+ cell epitope corresponding to a 15-amino acid sequence designated P10, which is recognized by T cells from mice infected with P. brasiliensis. Immunization of previously intratracheally infected BALB/c mice with P10 reduces the fungal load in the lungs more than 200-fold as compared to non-immunized animals (Taborda et al., 1998). P10 immunized animals produced greater amounts of IFN-γ and interleukin (IL)-12. These mice also had significantly reduced damage to lung tissue. In fact, the immune response elicited by P10 prevents the rapid spread of P. brasiliensis, and we have hypothesized that P10 administered as with newer adjuvants might enhance the immunoprotection by the peptide. Hence, we have begun to investigate the efficacy of different adjuvants co-administered with...
Virulent *P. brasiliensis* Alum has been associated with severe local reactions such as necrotizing dermatitis. Therefore, the use of CFA has been limited to experimental immunizations in animal studies. Due to the severity of adverse reactions, this adjuvant has been banned for use in humans as well as for non-experimental veterinary administration (Stills Jr., 2005).

The idea of using cationic lipids (dioctadecyl-dimethylammonium bromide, DODAB) as adjuvants arose from the effective uptake of microparticles by both dendritic cells and macrophages (Lincopan et al., 2009). Cationic polymer particles carry antigen to these phagocytes and can efficiently stimulate antibody production and activate cytotoxic T cells at low antigen dose (Singh et al., 2000; Lincopan et al., 2009). DODAB also induces maturation of dendritic cells (Thiele et al., 2001; Little et al., 2004) with high levels of IL-12 and IFN-\(\gamma\) production, which may be an important benefit in the design of an anti-fungal vaccine. In the present work, a comparative appraisal of the various adjuvants is presented aiming to identify which compound produces the most effective immune response to P10 using murine dendritic cells (Thiele et al., 2001; Little et al., 2004).

### MATERIALS AND METHODS

#### ANIMALS

Six male BALB/c mice per group (6- to 8-week old) were housed in polypropylene cages under specific pathogen free conditions. Animals used in this study were bred at University of São Paulo animal facility. All experiments involving animals were conducted in accordance with international recommendations.

#### FUNGAL STRAIN

Virulent *P. brasiliensis* Pb18 yeast cells were used to infect the animals. The strain was maintained by weekly passage on solid Sabouraud medium at 37°C and yeast cells were used after 7–10 days of growth. Before the experimental infection, the fungus was grown in modified McVeigh-Morton medium at 37°C for 5–7 days (Bastos and Arango, 1980). Fungal cells were washed in phosphate-buffered saline (PBS, pH 7.2) and counted in a hemocytometer. The viability of fungal suspensions was determined by staining with trypan blue (Sigma, St. Louis, MO, USA) and was always higher than 90%. The virulence of the Pb18 strain was checked in each experiment by infecting BALB/c mice i.t. and recovering the yeast cells from the infected organs.

#### IMMUNIZATION OF MICE

Immunization of BALB/c mice (6- to 8-week old males) was initiated 30 days after infection and repeated on days 37 and 44, by the subcutaneous route, with 20 μg of P10 in presence of the respective adjuvant. The adjuvants used were CFA with subsequent immunizations with incomplete Freund's adjuvant (IFA); Alum 100 μg/ml, FliC flagellin 5 μg/animal, and cationic lipid at 0.1 mM/animal. All adjuvants were vortexed with the peptide before immunization. The animals were sacrificed 7 days after the last immunization, at day 52 of infection.

#### COLONY FORMING UNITS

For each mouse, the lungs, spleen, and liver were excised and weighed immediately after sacrifice. Tissues were individually homogenized in PBS and 100 μl of this suspension was plated on brain heart infusion medium (BHI, Difco Laboratories, Detroit, MI, USA), supplemented with 4% fetal bovine serum (Gibco, NY, USA) and 5% of the spent culture medium of *P. brasiliensis* 192 isolate (Castaldini et al., 1988), streptomycin/penicillin 10 IU/ml (Cultilab, Brazil), and cycloheximide 500 μg/ml (Sigma, St Louis, MO, USA). The plates were incubated at 37°C for a period of 10 days. The numbers of colonies were counted and results expressed in colony forming unit (CFU) per gram of tissue.

#### CYTOKINE ANALYSIS

Lungs of each mouse were macerated with protease inhibitor (Sigma, St Louis, MO, USA) and centrifuged, supernatants of these samples were used for cytokine detection. IL-4, IL-10, TNF-\(\alpha\), and IFN-\(\gamma\) were measured using ELISA kits (BD Biosciences, San Diego, CA, USA). The detection limits of the assays were as follows: 7.8 pg/ml for IL-4, 31.25 pg/ml for IL-10 and IFN-\(\gamma\), and 15.6 pg/ml for TNF-\(\alpha\), as previously determined by the manufacturer. Cytokine levels present in the supernatant preparations were analyzed using GraphPad Prism 5.

After 30 days of infection, immunizations were initiated with three tissue in the livers of unimmunized mice.

Results

Colonies Forming Units in Infected BALB/c Mice Immunized with Peptide 10 (P10)

After 30 days of infection, immunizations were initiated with three weekly doses of P10 with or without the different adjuvants. After 52 days of infection, the fungal load was evaluated by enumeration of CFUs from recovered organs (lung, spleen, and liver). Lungs of mice immunized with P10 along with each of the different adjuvants had a significantly reduced number of CFU compared to controls (Figure 1). The order of efficacy for CFU reduction was cationic lipid and P10 > Flux/Fla > Alum > Flc. In this model, we did not recover any fungal cells from the spleens or livers of mice that received any of the immunizations with P10 (data not shown), demonstrating the effectiveness of the peptide in the control of experimental PCM. In contrast, the fungal burdens were 625 ± 60 CFU/g of tissue in the spleens and 296 ± 59 CFU/g of tissue in the livers of unimmunized mice.

CytoKine Pattern Induced by Immunization with P10 Associated with AdjuVants

In comparison with control infected animals, IFN-γ was significantly increased in mice that received P10 with either cationic lipid or Flc (Figure 2A). TNF-α levels were significantly increased only in mice treated with P10 and cationic lipid (Figure 2B). P10 immunization with either cationic lipid or Flc significantly reduced levels of IL-4 (Figure 2C) and IL-10 (Figure 2D). Immunization with P10 and Alum also reduced IL-10 levels, but did not significantly alter the levels of the other cytokines analyzed.

Lung Histopathology in BALB/c Mice Infected (I.I.) with P18 and Immunized with P10

Lung tissues from mice immunized with cationic lipid with or without P10 were stained with H&E and compared with unimmunized infected tissues as well as uninfected lungs (Figure 3). As expected, the non-infected group (Figure 3A) showed normal lung tissue, and the unimmunized infected lungs (Figure 3B) showed dense cell infiltrates with high numbers of fungal cells disseminated throughout the lung parenchyma. In the case of mice immunized only with the cationic lipid, we observed the formation of loose granulomas with many fungal cells (Figure 3C). In contrast, lungs of mice immunized with cationic lipid and P10 showed significantly preserved lung parenchyma without fungal cells (Figure 3D). The histological appearances of lungs from mice immunized with either Flc (Figure 3E) or Alum (Figure 3G) alone were similar to that with cationic lipid alone (Figure 3C). Immunization of mice with P10 and Flc resulted in improved granuloma formation in the lungs, which prevents the spread of the fungus, and increased preservation of normal lung parenchyma (Figure 3F). Although there was a slight increase in normal lung parenchyma in mice immunized with P10 and Alum, there was poor granuloma formation and large numbers of yeast cells within areas of inflammation (Figure 3H).

The amount of pulmonary collagen type I in mice immunized with P10 and Flc, Alum, or cationic lipid were compared with unimmunized infected controls using Masson’s trichrome staining. Tissues from control mice revealed abundant collagen I fibers within cellular infiltrates containing large numbers of fungal cells (Figure 4A). Although no fungal cells were visualized, lungs of mice immunized with Flc flagellin and P10 nevertheless diffusely displayed increased amounts of collagen (Figure 4B). Mice immunized with Alum and P10 showed large granulomas containing fungal cells and the formation of collagen fibers on the granuloma’s periphery (Figure 4C). In contrast, mice immunized with cationic lipid and P10 displayed preserved lung tissue without increased collagen (Figure 4D).

Discussion

The P10 peptide (QTLIAHHTLAIYAN) has important immunoprotective properties that make it a leading candidate for the development of a therapeutic vaccine (Taborda et al., 1998). We have also shown that P10 immunization can be utilized concomitantly with standard antifungal drugs in the treatment of PCM and that co-administration may also prevent disease recurrence (Marques et al., 2008).

The protective effect of P10 is related to the induction of an INF-γ dependent Th-1 immune response (Taborda et al., 1998; Travassos et al., 2007), so it may be stimulated by adjuvants or nanoparticle encapsulation that increase the efficiency of P10 uptake by dendritic cells resulting in the enhanced presentation of the peptide for cellular immune responses (Amaral et al., 2010; Magalhães et al., 2012). In the present work, we show that the association of P10 with cationic lipids led to a significant reduction of

Histopathology

The lungs were excised, fixed in 10% buffered formalin (Merck, Germany) and submitted to histopathological analysis (hematoxylin and eosin (H&E) and Masson’s trichrome).

Statistical Analysis

Statistics were done using GraphPad Prism 5 software (San Diego, CA, USA). The results were expressed as mean values and standard deviations (SDs) of the indicated values. The non-parametric Tukey’s honestly significant difference test was employed. p-Values ≤ 0.05 indicated statistical significance.

Discussion

The P10 peptide (QTLIAHHTLAIYAN) has important immunoprotective properties that make it a leading candidate for the development of a therapeutic vaccine (Taborda et al., 1998). We have also shown that P10 immunization can be utilized concomitantly with standard antifungal drugs in the treatment of PCM and that co-administration may also prevent disease recurrence (Marques et al., 2008).

The protective effect of P10 is related to the induction of an INF-γ dependent Th-1 immune response (Taborda et al., 1998; Travassos et al., 2007), so it may be stimulated by adjuvants or nanoparticle encapsulation that increase the efficiency of P10 uptake by dendritic cells resulting in the enhanced presentation of the peptide for cellular immune responses (Amaral et al., 2010; Magalhães et al., 2012). In the present work, we show that the association of P10 with cationic lipids led to a significant reduction of
FIGURE 2 | Cytokine detection was assayed in the lung tissue from BALB/c mice 52 days after infection. Analyzed cytokines were: (A) IFN-$\gamma$, (B) TNF-$\alpha$, (C) IL-4, and (D) IL-10. Each group was infected i.t. with $3 \times 10^5$ yeast cells and immunized at 30, 37, and 44 days after infection with different adjuvants with or without P10. The groups of mice included unimmunized, infected control mice (INF); animals infected and immunized with aluminum hydroxide alone (ALU) or with P10 (AP10), FliC flagellin alone (FLA) or with P10 (FP10), and cationic lipid alone (CLI) or with P10 (CP10). * $p < 0.05$: significance compared to control mice (only infected). ** $p < 0.01$: compared to control mice (only infected).

CFU in the lungs of 52-day-infected animals (Figure 1). In contrast, animals immunized only with P10 (without adjuvants), had minimal reductions in fungal burden (not shown data). Hence, combining adjuvants, such as cationic lipids, with P10 can generate augmented immune responses mediated by Th-1 cells, directly related to the secretion of IFN-$\gamma$ (Figure 2A), which leads to peritoneal and lung macrophage activation as well as enhancing their fungicidal effect on yeasts and conidia of *P. brasiliensis* (Buissaca-Filho et al., 2008). Immunization performed with P10 associated with antifungal drugs in animals infected with Pb18, has been shown to induce a significant reduction in IL-4 (Marques et al., 2008), which we now show also occurs in the setting of immunizations with cationic lipid and P10 (Figure 2C).

Studies with cationic lipids associated with recombinant HSP of *Mycobacterium leprae* have demonstrated the ability of the adjuvant to promote antigen presentation in lymph node cells with production of high levels of IL-12 and IFN-$\gamma$, suggesting that cationic lipid can be useful in the formulation of vaccines against intracellular bacteria, as well as against protozoa (Lincopan et al., 2009). IFN-$\gamma$ is required for the synthesis of TNF-$\alpha$ by macrophages and is essential for the accumulation of these cells and their subsequent differentiation into epithelioid cells. INF-$\gamma$ is also responsible for granuloma's formation and maintenance, and, therefore, it plays a vital role in the control of dissemination by fungi such as *P. brasiliensis* (Souito et al., 2000).

Although the cationic lipid/P10 association has demonstrated the best protective response in the setting of short-term infection in our murine model, it is relevant also to consider the protective effect of the association of P10 and FliC flagellin. A significant reduction in the number of CFU was observed and the cytokine profile was similar to that achieved with cationic lipid and P10.

(A) infected, unimmunized control mice, (B) infected and immunized with FliC flagellin plus P10, (C) infected and immunized with aluminum hydroxide plus P10, and (D) infected and immunized with cationic lipid plus P10 after 52 days of infection. Masson's trichrome staining, ×40 magnification. Blue staining and arrows indicate type I collagen fibers.

We have previously shown that prophylactic experiments performed with FliC flagellin have demonstrated the effectiveness of the association of this adjuvant with P10 allowing for the control of fungal infection in vaccinated mice (Braga et al., 2009). Intranasal immunization carried out with this formulation induced high levels of IFN-γ and IL-12 production by lung cells and suppressed the production of Th-2 cytokines. The formation of compact granulomas (Figure 3F) as well as cytokine levels obtained with FliC Flagellin and P10, can be associated to the administration route, since present immunizations were performed subcutaneously, according to Braga et al. (2009), better results are obtained with intranasal immunizations.

In the lung parenchyma, P. brasiliensis induces chronic damage leading to the development of pulmonary fibrosis, which is presumably due to persistent antigenic stimulation and an ongoing active immune response. Granulomatous inflammation can increase the formation of connective tissue rich in collagen type I and III, leading to functional changes and subsequent fibrosis in the lung (Naranjo et al., 2010). Since fibrosis is a well-known sequela of PCM, it is therefore important that the adjuvants used do not induce an exacerbated inflammatory response. In fact, the association of cationic lipid and P10 resulted in a significant reduction of pulmonary fibrosis in mice infected with Pb18 (Figure 4D).

In summary, we have shown that the examined regimens combining P10 with different adjuvants results in significantly different protective responses. Administration of P10 with cationic lipid provided the most effective response profile, with the greatest reduction in fungal burden and a Th-1 biased cytokine response that maintained pulmonary architecture without inducing fibrotic injury.
