To D. B. Fuchs on his 60-th birthday

Abstract. We study finitely generated projective modules over noncommutative tori. We prove that for every module $E$ with constant curvature connection the corresponding element $[E]$ of the K-group is a generalized quadratic exponent and, conversely, for every positive generalized quadratic exponent $\mu$ in the K-group one can find such a module $E$ with constant curvature connection that $[E] = \mu$. In physical words we give necessary and sufficient conditions for existence of $1/2$ BPS states in terms of topological numbers.

1 Introduction.

In present paper we study projective modules over non-commutative tori. (We always consider finitely generated projective modules.) Our main goal is to describe all modules that admit constant curvature connections. It is well known that constant curvature connections correspond to maximally

supersymmetric BPS fields \([\text{C-D-S}]\); this means that we give conditions for existence of 1/2 BPS states.

The main results of the paper are formulated in the following theorems.

**Theorem 1.1** Let \(A_\theta\) be a non-commutative torus. Then for every projective \(A_\theta\) module \(E\) with a constant curvature connection corresponding element of the group \(K_0(A_\theta)\) is a generalized quadratic exponent. Conversely, if \(\mu\) is a positive generalized quadratic exponent in \(K_0(A_\theta)\) then there exists such a projective module \(E\) with constant curvature connection that \([E] = \mu\). (Here \([E]\) stands for the K-theory class of \(E\). The definition of generalized quadratic exponent will be given later.)

**Theorem 1.2** Let \(A_\theta\) be an irrational non-commutative torus. In this case projective modules over \(A_\theta\) which admit constant curvature connection are in one-to-one correspondence with positive generalized quadratic exponents in \(K_0(A_\theta)\).

This theorem is an immediate consequence of Theorem 1 and of the following very strong result by M. Rieffel (see \([\text{Rf1}]\)): for irrational non-commutative torus \(A_\theta\) projective modules \(E\) and \(F\) are isomorphic if and only if the classes \([E], [F] \in K_0(A_\theta)\) are equal.

Our main results were formulated and partially proved in \([\text{K-S}]\), Appendix D. It is assumed in \([\text{K-S}]\) that every linear combination of entries of the matrix \(\theta\) is irrational. It is proved that in this case a projective module can be transformed into a free module by means of complete Morita equivalence iff corresponding K-theory class is a generalized quadratic exponent. This statement can be used to prove Theorem 1.1 in the conditions of Appendix D of \([\text{K-S}]\).

The paper is organized as follows. In the introduction we remind the main notions and results we need and explain how we plan to prove the main theorem. In the section 2 we introduce the notion of generalized quadratic exponent and we study its properties. Section 3 is about integral generalized quadratic exponents and finite dimensional representations of rational non-commutative tori. In section 4 we present a proof of main results.

Let us remind the definition of a non-commutative torus (see \([\text{Rf2}]\) for more details). Let \(L\) be a lattice \(\mathbb{Z}^n\) in a vector space \(V^* = \mathbb{R}^n\). Let \(\theta\) be real valued skew-symmetric bilinear form on \(\mathbb{R}^n\). We will think about
θ as a two-form, that is an element of $\Lambda^2 V$. Non-commutative torus $A_\theta$ is the universal $C^*$-algebra generated by unitary operators $U_\alpha$, $\alpha \in L$ obeying relations

$$U_\alpha U_\beta = e^{2\pi i \theta(\alpha, \beta)} U_{\alpha + \beta}.$$ (1)

Any element from $A_\theta$ can be represented uniquely by a sum $a = \sum_{\alpha \in L} c_\alpha U_\alpha$, where $c_\alpha$ are complex numbers. Assigning to every $a \in A_\theta$ the coefficient $c_0$ in the representation above we obtain a canonical trace $\tau$ on $A_\theta$.

Let $\{e_i\}$ be a basis of $L$. One can say that $A_\theta$ is the universal $C^*$-algebra generated by unitary operators $U_1, \cdots, U_n$ obeying the relations

$$U_i U_j = e^{2\pi i \theta(e_i,e_j)} U_j U_i.$$ (2)

To check that these two definitions are equivalent one should take $U_i = U_{e_i}$.

The transformations $\delta_k U_{e_k} = U_{e_k}$, $1 \leq k \leq n$, $\delta_l U_{e_k} = 0$, $k \neq l$, $1 \leq k, l \leq n$ can be regarded as generators of Abelian Lie algebra $L_\theta$ of infinitesimal automorphisms on $A_\theta$. We can naturally identify $L_\theta$ with $V$. Let us remind the definition of a connection in a $A_\theta$-module following [Con1] (we do not need the general notion of connection [Con2]). First we need the notion of a smooth part of a projective module.

Any element from $A_\theta$ can be considered as a (generalized) function on the n-dimensional torus whose Fourier coefficients are $c_\alpha$ (see above). The space of smooth functions on $T^n$ forms a subalgebra of $A_\theta$. We denote it by $A_\theta^{smooth}$ and call it the smooth part of $A_\theta$. If $E$ is a projective $A_\theta$ module one can define its smooth part $E^{smooth}$ in a similar manner (see [HL]). A connection on projective module $E$ can be defined as follows:

An $A_\theta$ connection on a right $A_\theta$ module $E$ is a linear map $\nabla : L_\theta \to \text{End}_C E$, satisfying the condition

$$\nabla_\delta (ea) = (\nabla_\delta e)a + e(\delta(a)), $$

where $e \in E^{smooth}$, $a \in A_\theta^{smooth}$, and $\delta \in L_\theta$. The curvature $F_{\mu,\nu} = [\nabla_\mu, \nabla_\nu]$ of connection $\nabla$ is considered as a two-form on $L_\theta$ with values in $\text{End}_{A_\theta} E$. (Here $\text{End}_{A_\theta} E$ stands for the space of endomorphisms of $A_\theta^{smooth}$ module $E^{smooth}$ and $\text{End}_C E$ denotes the space of $C$-linear endomorphisms of $E^{smooth}$.)

We always consider Hermitian modules and Hermitian connections. This means that if $E$ is a right $A_\theta$ module it is equipped with $A_\theta$ valued Hermitian inner product $\langle \cdot, \cdot \rangle$ (for the detailed list of properties see [BL]) ; all connections that we will consider should be compatible with this inner product.
If $E$ is endowed with a $\mathcal{A}_\theta$-connection, then one can define a Chern character

$$\text{ch}(E) = \sum_{k=0} \hat{\tau}(F^k) \frac{2\pi i}{k!} = \hat{\tau}(e^{F}),$$

(3)

where $F$ is a curvature of a connection on $E$, and $\hat{\tau}$ is the canonical trace on $\mathcal{A} = \text{End}_{\mathcal{A}_\theta}(E)$ (we use that $\mathcal{A}_\theta$ is equipped with a canonical trace $\tau = c_0$).

One can consider $\text{ch}(E)$ as an element in the Grassmann algebra $\Lambda^\cdot (L^\theta)^\ast = \Lambda^\cdot (V^\ast)$. We have a lattice $L$ in $V^\ast$. Thus we can talk about integral elements in $\Lambda^\cdot (V^\ast)$ which are just the elements of $\Lambda^\cdot L$. In the commutative case $\text{ch}(E)$ is integral. In non-commutative case this is wrong, but there exists some integral element $\mu(E) \in \Lambda^\cdot (V^\ast)$ related to $\text{ch}(E)$ by the formula (see [Ell], [Rf1])

$$\text{ch}(E) = e^{i(\theta)} \mu(E),$$

(4)

Here $i(\theta)$ stands for the operation of contraction with $\theta$ considered as an element of $\Lambda^2 V$. In particular, formula (4) means that $e^{-i(\theta)} \text{ch}(E)$ is an integral element of $\Lambda^\cdot (V^\ast)$. The group $\Lambda^\text{even} L$ can be naturally identified with the group $K_0(\mathcal{A}_\theta)$. Moreover $\mu(E)$ is the class of the module $E$ in the $K_0(\mathcal{A}_\theta)$ group (see [Ell]).

Let us remind that the element $\mu \in K_0(\mathcal{A}_\theta)$ is called positive if $(e^{i(\theta)} \mu)_{(0)} > 0$ (the zero component is positive). A well known theorem of M. Rieffel (see [Rf1]) says that if $\theta$ is irrational then every positive element of $\mu$ is represented by a projective module over $\mathcal{A}_\theta$.

Let $E$ be a projective $\mathcal{A}_\theta$ module with a constant curvature connection $\nabla$. Denote by $F$ the curvature of $\nabla$. Then since $F$ is a 2-form with values in $\mathbb{C}$ we obtain that $\hat{\tau}(F^k) = \hat{\tau}(1) F^k$. The number $\hat{\tau}(1)$ is called the dimension of the module $E$ and we denote it by $d_E$. Then the formula (3) becomes

$$\text{ch}(E) = d_E e^{\frac{F}{2\pi i}}.$$  

(5)

We see that in this case $\text{ch}(E)$ is a quadratic exponent (i.e. an expression of the form $Ce^a$ where $C$ is a constant and $a \in \Lambda^2(V^+)$). It follows from (4) and from this fact that $\mu(E)$ is a generalized quadratic exponent (i.e. a limit of quadratic exponents). This gives a proof of the first statement of Theorem 1.1. The proof of the second statement of this theorem is based on the study of generalized quadratic exponents in sections 2 and 3. In section 3 we will study integral generalized quadratic exponents keeping in mind that $K_0(\mathcal{A}_\theta)$ is exactly the integral lattice in $\Lambda^\text{even}(V)$, where $V = L^\theta^\ast$. We will prove
some auxiliary technical results saying that something is rational or integral which we will use in our construction of the module in section 4.

In section 4 we will construct a desired module together with constant curvature connection in four steps.

First we find explicitly the curvature $F$ as a 2-form on $L_\theta$.

Second, we construct some spaces of functions on $\mathbb{R}^p \times \mathbb{Z}^{n-2p}$ with action of generators of some non-commutative torus $A_\bar{\theta}$ and with constant curvature connection having the curvature form $F$. We do not construct an $A_\bar{\theta}$ module at this step. Moreover, we even will not specify what space of functions we will take.

Third, we will check that our construction in the previous step is just a particular case of Rieffel’s construction in [Rf1] where he constructs $A_\bar{\theta}$ projective modules. So we can construct the desired module $\tilde{E}$ over $A_\bar{\theta}$ using Rieffel’s construction.

Fourth, we will see that $\tau = \theta - \tilde{\theta}$ is a rational element of $\Lambda^2 L_\theta = \Lambda^2 V^*$. Also, we will use Rieffel’s explicit calculation of $[\tilde{E}]$ (of the class of $\tilde{E}$ in $K_0(A_\bar{\theta}) \subset \Lambda^{even}(V)$ )to find a simple relation between $[\tilde{E}]$ and $\mu$. Finally, we show that we can construct a projective module $E$ with constant curvature connection over $A_\theta$ such that $[E] = \mu$ by taking $E$ to be a tensor product of $\tilde{E}$ by some finite dimensional module $M$ over $A_\tau$.

2 Generalized quadratic exponents.

In this section we introduce generalized quadratic exponents and study their properties.

Let $V$ be a finite dimensional vector space over $\mathbb{R}$. Let $V^*$ be a dual space. Then the space $V \oplus V^*$ has a natural symmetric bilinear product given by

$$\langle (x_1, y_1), (x_2, y_2) \rangle = y_2(x_1) + y_1(x_2),$$

where $x_1, x_2 \in V$ and $y_1, y_2 \in V^*$. Consider a Clifford algebra $\text{Cl}(V \oplus V^*)$. It naturally acts on the vector space $\Lambda(V)$; we denote this action by $\rho$. Note, that there is a natural inclusion $i$ of $V \oplus V^*$ into $\text{Cl}(V \oplus V^*)$.

**Definition 2.1** An element $q \in \Lambda(V)$ is called a generalized quadratic exponent if there exists a maximal isotropic subspace $U \subset V \oplus V^*$ such that for any $x \in U$ we have $\rho(x)q = 0$. 

If the projection of $U$ onto $V^*$ is bijective we can represent $U$ as a graph of a linear operator $a : V^* \to V$. The operator $a$ is antisymmetric; it can be considered as an element of $\Lambda^2(V)$. The element $q$ can be represented in the form $\text{const} \cdot e^a$, i.e. it is a quadratic exponent. The set of maximal isotropic subspaces we just considered is dense in the set of all maximal isotropic subspaces; this means that quadratic exponents are dense in the set of all generalized quadratic exponents.

In the next proposition we will describe all possible generalized quadratic exponents.

**Proposition 2.1** Let $q \in \Lambda^2(V)$ be a generalized quadratic exponent. Then there exists a subspace $W \subset V$, a non-degenerate element $\tilde{q}_1 \in \Lambda^2(V/W)$ and nonzero element $w \in \Lambda^\dim W W$ such that
\[
q = w \wedge e^{\tilde{q}_1}.
\]
where $q_1 \in \Lambda^2(V)$ is any preimage of $\tilde{q}_1 \in \Lambda^2(V/W)$ under the natural projection from $\Lambda^2(V)$ onto $\Lambda^2(V/W)$.

**Proof:** Let $U$ be the maximal isotropic subspace corresponding to $q$. It is easy to see that we can choose a basis $\{\xi_i\}$ of $V$ and a dual basis $\{\eta_i\}$ of $V^*$ such that $U$ is spanned by the vectors $\eta_1 - \sum_{i=1}^j a_{1,i} \xi_i, ..., \eta_j - \sum_{i=1}^j a_{j,i} \xi_i, \xi_{j+1}, ..., \xi_{\dim W}$. Thus, $q$ satisfies the following system of equations:
\[
\begin{align*}
\frac{\partial q}{\partial \xi_1} - (\sum_{i=1}^j a_{1,i} \xi_i) \wedge q &= 0 \\
&\vdots \\
\frac{\partial q}{\partial \xi_j} - (\sum_{i=1}^j a_{j,i} \xi_i) \wedge q &= 0 \\
\xi_{j+1} \wedge q &= 0 \\
&\vdots \\
\xi_{\dim W} \wedge q &= 0 
\end{align*}
\]

The partial derivatives in this system are understood as left derivatives in the sense of superalgebra.
It is easy to see that any solution of this system is of the form
\[ C \cdot \xi_{j+1} \wedge \cdots \wedge \xi_{\dim W} \wedge e^{\sum_{k=1}^{j} \sum_{l=1}^{j} a_{k,l} \xi_k \wedge \xi_l}, \]
where C is a constant. The proposition follows easily from the above formula. 
\( W \) is the subspace spanned by \( \xi_{j+1}, \cdots, \xi_{\dim W} \) and \( \bar{q}_1 \) is the projection of \( \sum_{k=1}^{j} \sum_{l=1}^{j} a_{k,l} \xi_k \wedge \xi_l \).

Q.E.D.

\( \Lambda (V) \) is a graded vector space. If \( q \in \Lambda (V) \) let us denote by \( q \in \Lambda V \) the projection \( q \) on \( \Lambda V \).

**Corollary 2.1** Let \( q \) be a generalized quadratic exponent. If \( q(0) \) is not zero then there is a non-degenerate element \( a \in \Lambda^2 V \) and a nonzero real number \( C \) such that
\[ q = Ce^a. \]

**Proof:** Immediately follows from Proposition 2.1.

Q.E.D.

Let \( b \in \Lambda^2 (V^*) \). Then \( b \) acts naturally on \( \Lambda (V) \). If we choose basis \( \{ \xi_i \} \) in \( V \) then we can write the action of \( b \) as \( \sum_{k,l} b_{k,l} \frac{\partial}{\partial \xi_k \partial \xi_l} \). Another way of thinking is to think about \( b \) as an element of \( \text{Cl}(V \oplus V^*) \). We have a canonical map from \( \Lambda^*(V^*) \) to \( \text{Cl}(V \oplus V^*) \) since \( V^* \) is isotropic subspace in \( V \oplus V^* \). Then the action of \( b \) is simply \( \rho (b) \).

**Proposition 2.2** Let \( q \) be a generalized quadratic exponent and \( b \) any element in \( \Lambda^2 (V^*) \). Then \( e^{\rho (b)} q \) is a generalized quadratic exponent.

**Proof:** We will reduce the proposition to the case where \( b \) is decomposable. Since, \( \rho (b) = \sum_{k,l} b_{k,l} \frac{\partial}{\partial \xi_k \partial \xi_l} \) in some basis \( \{ \xi_i \} \) of \( V \) and the operators \( \frac{\partial}{\partial \xi_k \partial \xi_l} \) commute it is enough to prove the proposition in the case when \( \rho (b) = c \frac{\partial}{\partial \xi_k \partial \xi_l} \), where \( c \) is a real number. In this case \( e^{\rho (b)} = 1 + \rho (b) \).

Our goal is to show that there exists a subspace \( \tilde{W} \subset V \oplus V^* \) such that for any \( x \in \tilde{W} \) we have \( \rho (x)(q + \rho (b)(q)) = 0 \).

Let \( W \) be a subspace of \( V \oplus V^* \) such that if \( x \in W \) then \( \rho (x)q = 0 \). We can choose a basis \( \{ v_1 + w_1, \cdots, v_k + w_k, v_{k+1}, \cdots, v_{\dim W} \} \) of \( W \), where \( v_i \in V^* \) and \( w_i \in V \), and the vectors \( \{ w_i \} \) are linearly independent.

A simple calculation shows that
\[ \rho (v_i)(q + \rho (b)(q)) = 0 + \rho (v_i)\rho (b)(q) = \rho (b)\rho (v_i)(q) = 0, \]

for $l > k$. Also, we can easily see that for $l < k + 1$
\[
\rho(v_l + w_l)(q + \rho(b)(q)) = \rho(v_l + w_l)\rho(b)(q) =
\]
\[
[\rho(v_l + w_l), \rho(b)](q) + \rho(b)\rho(v_l + w_l)(q) = [\rho(w_l), \rho(b)](q) = \rho(\iota(w_l)b)q.
\]
where $\iota(w_l)$ is plugging the vector $w_l$ in the 2-form $b$. $\iota(w_l)b$ is an element of $V^*$. Since $b^2 = 0$ we see that $0 = \iota(w_l)(b^2) = 2(\iota(w_l)b)b$. Thus,
\[
\rho(\iota(w_l)b)q = \rho(\iota(w_l)b + (\iota(w_l)b)b)q = \rho(\iota(w_l)b)(q + \rho(q)).
\]
Therefore, we see that
\[
\rho([v_l - \iota(w_l)b] + w_l)(q + \rho(b)q) = 0.
\]
Denote by $\tilde{W}$ the subspace of $V \oplus V^*$ spanned by the vectors $[v_l - \iota(w_l)b] + w_1, \ldots, [v_k - \iota(w_k)b] + w_k, v_{k+1}, \ldots, v_{\dim W}$. It is easy to check that $\tilde{W}$ is a maximal isotropic subspace of $V \oplus V^*$ and we showed that $\rho(x)(q + \rho(b)q) = 0$ for any $x \in \tilde{W}$. Thus, $q + \rho(b)q$ is a generalized quadratic exponent.

Q.E.D.

3 Integral generalized quadratic exponents.

In this section we study integral generalized quadratic exponents and we prove a couple of auxiliary propositions that we will use in our construction.

Let $V$ be a finite dimensional vector space and let $L$ be a lattice in it. Denote by $n$ the dimension $V$. Then, $V \cong \mathbb{R}^n$ and $L \cong \mathbb{Z}^n$. We denote the dual lattice to $L$ by $L^*$. Obviously $L^* \subset V^*$. We call an element of $\Lambda(V)$ integral if it lies in $\Lambda L$.

Define $U_\mu$ a subspace of $V^*$ as follows:

\[
U_\mu = \{x \in V^* \mid \iota(x)\mu = 0\}.
\]

Denote by $W_\mu \subseteq V$ the orthogonal complement to $U_\mu$.

**Proposition 3.1** Let $\mu \in \Lambda(V)$ be an integral generalized quadratic exponent. Then $L_\mu = L \cap W_\mu$ is a lattice in $W_\mu$. We can identify $\Lambda^{\dim W_\mu} L_\mu$ with $\mathbb{Z}$ (the isomorphism is not canonical but it is specified up to a sign). Let $\alpha \in \Lambda^{\dim W_\mu} L_\mu$ be a volume form (an element that corresponds to 1 under the isomorphism with $\mathbb{Z}$). Then $\mu(\dim W_\mu) = N\alpha$, where $N$ is a nonzero integer.
Proof: Let $\mu \in \Lambda(V)$ be an integral generalized quadratic exponent. Let $k$ be the largest integer such that $\mu(k) \neq 0$ and for all $l > k$ we have $\mu(l) = 0$. From Proposition 2.1 easily follows that $U_\mu = \{x \in V^* \mid \iota(x)\mu = 0\} = \{x \in V^* \mid \iota(x)\mu(k) = 0\}$. Moreover, from Proposition 2.1 follows that $\mu(k)$ is a decomposable element of $\Lambda(V)$ and that $k = \dim V - \dim U_\mu = \dim W_\mu$. Since $\mu$ is integral $\mu(k)$ is also integral. Thus, the subspace $U_\mu$ is spanned by $U_\mu \cap L^*$. Therefore, $U_\mu \cap L^*$ is a lattice in $U_\mu$. This immediately implies that $L_\mu = W_\mu \cap L$ is a lattice in $W_\mu$ since $W_\mu$ is the orthogonal complement to $U_\mu$.

From the above discussion it is easy to see that $\Lambda^{\dim W_\mu}(W_\mu \cap L) = \Lambda^{\dim W_\mu}L_\mu \cong \mathbb{Z}$. Since, by the definition $\alpha$ corresponds to $\pm 1$ under such an isomorphism and $\mu(\dim W_\mu) = \mu(k)$ is an integral element we obtain that $\mu(\dim W_\mu) = N\alpha$ for some integer $N$.

Q.E.D.

Under the conditions in the above proposition we can easily find a complement $\tilde{L}_\mu (\tilde{L}_\mu \cong \mathbb{Z}^{\dim W_\mu})$ to $L_\mu$ in $L$. It is not unique but we do not care about that. Let $Y_\mu$ be the subspace of $V$ spanned by $\tilde{L}_\mu$. Then it is obvious that $V = W_\mu \oplus Y_\mu$ and $L = L_\mu \oplus \tilde{L}_\mu$.

Next results will be used in the construction in section 4.1. Since, they do not use any theory of non-commutative tori we state them here. But they need some explanation concerning their origin.

Let $\mu \in \Lambda^\text{even}(V)$ be an integral generalized quadratic exponent which will be an element of $K_0$ representing a projective module of $A_\theta$. We can think about $\theta$ as an element of $\Lambda^2 V^*$. If there exists a projective module $E$ over $A_\theta$ with constant curvature connection such that $[E] = \mu$ then by the result of G. Elliott (see [Ell]) $d e^{\iota(\theta)\mu} = e^{\iota(\theta')\mu}$, where $d$ is the dimension of the module. $\tilde{\theta}$ which satisfies the conditions of the lemma below will be constructed in section 4.1.

\textbf{Lemma 3.1} Let $\mu \in \Lambda^\text{even}(V)$ be an integral generalized quadratic exponent. Let us assume that we fixed the isomorphism between $\Lambda^{\dim W_\mu}L_\mu$ and $\mathbb{Z}$ (see Proposition 3.1) so that $\mu(\dim W_\mu) = N\alpha$ with $N$ being natural number (here $\alpha \in \Lambda^{\dim W_\mu}L_\mu$ corresponds to 1 in $\mathbb{Z}$). Let $\theta$ and $\tilde{\theta}$ be elements of $\Lambda^2 V^*$ such that $\theta - \tilde{\theta}$ is zero on $V \otimes Y_\mu$ (that is if $X_\mu \subset V^*$ is the orthogonal complement to $Y_\mu$ then $\theta - \tilde{\theta} \in \Lambda^2 X_\mu$). Assume that

\[ e^{\iota(\theta)\mu} = ce^{\iota(\tilde{\theta})\alpha}, \]
where $c$ is a real number. Then $c = N$, that is

$$e^{i\theta} \mu = Ne^{i\bar{\theta}} \alpha,$$

and $N(\theta - \bar{\theta})$ is an integral element of $\Lambda^2 X_{\mu}$.

**Proof:** Let us denote $\dim W_\mu$ by $k$. Then formula (5) implies that

$$\mu_{(k)} = (e^{i\theta} \mu)_{(k)} = c(e^{i\bar{\theta}} \alpha)_{(k)} = c\alpha_{(k)}.$$ 

Thus, $c = N$ and we proved formula (7). From formula (6) it easily follows that

$$\mu = Ne^{i(\bar{\theta} - \theta)} \alpha.$$ 

This means that $\mu_{k-2} = N(\theta - \bar{\theta}) \alpha$. $\mu_{k-2}$ is an integral element. $\bar{\theta} - \theta$ is in $\text{dim} W_\mu$ which is dual to $W_\mu$ and $\alpha$ is a nonzero element of $\Lambda^{\text{dim} W_\mu} W_\mu$. Thus, $N(\bar{\theta} - \theta)$ is an integral element of $\Lambda^2 X_{\mu}$.

Q.E.D.

### 3.1 Modules over the rational non-commutative tori.

Let us assume that conditions of Lemma 3.1 are satisfied. We denote $\theta - \bar{\theta}$ by $\tau$. Let us remind the definition of $\mathcal{A}_\tau$. $\mathcal{A}_\tau$ is a universal $\mathbb{C}^*$ algebra having unitary generators $U_\beta$, where $\beta \in L$, obeying the relations

$$U_\beta U_\gamma = e^{-i\pi r(\beta_1, \gamma_1)} U_{\beta_1 + \gamma_1}.$$ 

We can reformulate this definition in a slightly different way. Let $\beta_1, \ldots, \beta_n$ (where $n = \dim V$) be a basis of a free $\mathbb{Z}$ module $L$. $\mathcal{A}_\tau$ is a universal $\mathbb{C}^*$ algebra having unitary generators $U_i$, $1 \leq i \leq n$, obeying the relations

$$U_i U_j = e^{2\pi i r(\beta_i, \beta_j)} U_j U_i.$$

It is obvious that the two definitions are equivalent.

**Proposition 3.2** Under the conditions of Lemma 3.1 there exists an $N$ dimensional module $M$ over $\mathcal{A}_\tau$. 

10
Proof: Since $N\tau$ is integral form and we have a freedom in choosing a basis $\{\beta_i\}$ of $L$, we can choose it so that

$$N\tau(\beta_{2i-1}, \beta_{2i}) = q_1 q_2 \cdots q_i,$$

$$\tau(\beta_k, \beta_l) = 0 \text{ unless } k = 2i - 1 \text{ and } l = 2i \text{ or } k = 2i \text{ and } l = 2i - 1,$$

where $q_1, q_2, \cdots$ are integers (see [12]) and moreover the basis $\{\beta_i\}$ respects the decomposition of $L$ into $L_\mu \oplus \tilde{L}_\mu$. In this basis the algebra $A_\tau$ is generated by unitary generators $U_i$ obeying the relations

$$U_{2i-1} U_{2i} = e^{2\pi i \frac{N q_i}{N}} U_{2i} U_{2i-1} \quad (9)$$

(all other generators commute). Note that it may happen that there exists an integer $m$ such that if $i > m$ then all $q_i$ are zero.

So we see that our algebra $A_\tau$ is a tensor product of algebras $A_{\tau i}$, where $A_{\tau i}$ is generated by two unitary generators $U_{2i-1}$ and $U_{2i}$ obeying relations (9) or $A_{\tau i}$ is generated by only one unitary generator (this is the case when $i > m$, in particular if $\beta_i \in \tilde{L}_\mu$). Thus it is enough to show that we can construct finite dimensional modules $M_i$ over $A_{\tau i}$ such that $(\dim M_1)(\dim M_2) \cdots$ divides $N$. Really, in such case we can take $M$ to be the direct sum of $M_1 \otimes M_2 \otimes \cdots$ taken $\frac{N}{\dim M_1 \dim M_2 \cdots}$ times.

If $A_{\tau i}$ is generated by one unitary generator then it has a 1 dimensional module over it, $U_i$ acts by 1. We choose $M_i$ to be this module in this case.

If $A_{\tau i}$ is generated by two unitary generators $U_{2i-1}$ and $U_{2i}$ obeying relations (9) then it has a module of dimension $\frac{N}{\gcd(N, q_1 \cdots q_i)}$, where $\gcd$ stands for greatest common divisor. We choose $M_i$ to be a module of the dimension $\frac{N}{\gcd(N, q_1 \cdots q_i)}$.

Thus, it is enough to show that $\frac{N^m}{\gcd(N, q_1 \cdots q_i) \cdot \gcd(N, q_{i+1} \cdots q_m)}$ divides $N$, where $m$-the number of tori $A_{\tau i}$ generated by two generators. Therefore it is enough to prove that $\frac{\gcd(N, q_1 \cdots q_i) \cdot \gcd(N, q_{i+1} \cdots q_m)}{N^{m-1}}$ is an integer.

Lemma 3.2

$$\frac{\gcd(N, q_1) \cdots \gcd(N, q_1 \cdots q_m)}{N^{m-1}}$$

is an integer if

$$q_1^2 q_2 \cdots q_1 q_2^2 \cdots q_m^m$$

are integers.
Proof: Denote by $a_i$ the $\frac{\text{GCD}(N,q_1 \cdots q_i)}{\text{GCD}(N,q_1 \cdots q_{i-1})}$ and $b_i = q_i / a_i$. Then we can write $q_1^m q_2^{m-1} \cdots q_m = (a_1^m a_2^{m-1} \cdots a_m) (b_1^m b_2^{m-1} \cdots b_m)$. We will prove by induction that $\frac{a_{k-1} a_{k-2} \cdots a_1}{N^{k-1}}$ are integers. The initial case $k = 1$ is obvious. For $k > 1$ we have\[
frac{a_1^{k-1} a_2^{k-2} \cdots a_k}{N^{k-1}} = \frac{a_1^{k-1} a_2^{k-2} \cdots a_{k-1}}{N^{k-2}} \left( \frac{a_1 \cdots a_k}{N} \right) \cdot \nfrac{b_1 b_2^{k-1} \cdots b_k}{N}.
\]
Thus, $\frac{a_{k-1} a_{k-2} \cdots a_1}{N^{k-1}} \left( \frac{a_1 \cdots a_k}{N} \right)$ is an integer. Q.E.D.

To prove the proposition it is enough to show that $q_1 q_2^{k-1} \cdots q_k = a_1^{k-1} a_2^{k-2} \cdots a_{k-1} \left( \frac{a_1 \cdots a_k}{N} \right) \left( b_1 b_2^{k-1} \cdots b_k \right)$.  Thus, $\frac{a_{k-1} a_{k-2} \cdots a_1}{N^{k-2}} \left( \frac{a_1 \cdots a_k}{N} \right)$ is an integer.

4 Proof of Theorem 1.1.

First, let us show that if we have a projective $A_\theta$-module with constant curvature connection then the corresponding class $\mu = [E] \in K_0(A_\theta)$ is a positive generalized quadratic exponent.
Really, we know from formula 4 that
\[ \mu = \left[ E \right] = e^{-i(\theta)} \text{ch}(E) = e^{i(-\theta)} \text{ch}(E). \]

Also, from formula 5 we see that
\[ \text{ch}(E) = d_E e^{\frac{F}{2\pi i}}. \]

Thus \( \text{ch}(E) \) is a generalized quadratic exponent since \( F \) is an element of \( \Lambda^2 V \) (recall that \( V = L_{\theta}^* \)). From Proposition 2.2 it immediately follows that \( \mu \) is a generalized quadratic exponent since \( -\theta \in \Lambda^2(V^*) \). Therefore we proved that \( \mu = [E] \) is a generalized quadratic exponent. It is a positive element of \( K_0(A_\theta) \) because it represents a genuine \( A_\theta \) module. Thus we proved the statement of Theorem 1.1 in one direction.

This was the easy part. The hard part is to prove the second half, that is to show that if \( \mu \in K_0(A_\theta) \) is a positive generalized quadratic exponent then there exists a projective module \( E \) with a constant curvature connection which represents the class \( \mu \), i.e., \( \mu = [E] \). In the next subsection we present an explicit construction of such a module.

### 4.1 Construction of \( A_\theta \)-module \( E \) with constant curvature connection.

In this section we will construct explicitly a \( A_\theta \)-module \( E \) with a constant curvature connection over representing \( \mu \in K_0(A_\theta) \). Assuming that such a module exists we see that \( \text{ch}(E) = e^{i(\theta)} \mu \) is a generalized quadratic exponent (follows from Proposition 2.2 and the fact that \( \mu \) is a generalized quadratic exponent). Moreover, \( \text{ch}(E)(0) > 0 \) therefore from Corollary 2.1 follows that
\[ \text{ch}(E) = e^{i(\theta)} \mu = d_E e^{\frac{F}{2\pi i}}, \]

where \( F \) is the curvature form, and \( d_E \) is the dimension of the module \( E \). Thus, reversing the previous arguments it is obvious that it is enough to construct a projective \( A_\theta \)-module with constant curvature connection satisfying the following properties
a) the curvature form is \( F \);
b) the dimension of the module is \( d_E \).
In Section 3 we defined a subspace $W^*_\mu \subseteq V = L^*_\theta$ associated with the
generalized quadratic exponent $\mu$. Since $\mu \in K_0(A_\theta)$ we see that $\mu$ is integral.
Thus, $L_\mu = L \cap W^*_\mu$ is the integral lattice in $W^*_\mu$ by Proposition 3.1. As in section 3 we denote by $k = \dim W^*_\mu$ and we choose a complement $L_\mu$ to $L_\mu$ in $L$. Denote by $Y_\mu$ the span of $\tilde{L}_\mu$ in $V$. It is obvious that $L^*_\theta = V = W^*_\mu \oplus Y^*_\mu$.
Thus, we have a natural decomposition $L_\theta = V^* = W^*_\mu \oplus Y^*_\mu$. Note that the
space $Y^*_\mu = U_\mu$ was defined in section 3. Since $\mu(k) = d_E(e^{2\pi i k})$ $k$ is even integer, that is $k = 2p$, $p \in \mathbb{Z}$. Denote by $q$ the rank of the free abelian
group $\tilde{L}_\mu$. We have $q = n - 2p$, where $n = \dim L_\theta$ the dimension of $A_\theta$. Since $F^p$ is nonzero it follows that $F|W^*_\mu$ ($F$ restricted to $W^*_\mu$) is a non-degenerate
2-form.

4.1.1 Construction of operators $\nabla_x$ for $x \in L_\theta$.

Let $Heis$ be a Heisenberg algebra generated by the operators $\nabla_x$, for $x \in W^*_\mu$
which satisfy the relation

$$[\nabla_x, \nabla_y] = F(x, y),$$

where $x, y \in W^*_\mu$. The algebra $Heis$ has a unique irreducible representation
which can be realized in the space of square integrable functions on $\mathbb{R}^p$. Moreover, the action of $\nabla_x$ is given by an operator

$$(\nabla_x(f))(z) = 2\pi i \langle \phi(x), z \rangle f(z) + \sum_i \psi_i(x) \frac{\partial f(z)}{\partial z_i},$$

where $\phi : W^*_\mu \to (\mathbb{R}^p)^*$ is some linear map, and $\psi_i : W^*_\mu \to \mathbb{R}$ are some
linear functions on $W^*_\mu$. In particular, we see that these operators preserve
the space of Schwartz functions on $\mathbb{R}^p$.

The above construction provides us with the action of the operators $\nabla_x$
for $x \in W^*_\mu$ only. First we will extend the above construction to obtain an
action of all operators $\nabla_x$, $x \in L_\theta = W^*_\mu \oplus Y^*_\mu$. Then, we will obtain an action
of some non-commutative torus $A_{\tilde{\theta}}$ so that $\nabla$ becomes an $A_{\tilde{\theta}}$ connection.

We extend the space from the space of Schwartz functions on $\mathbb{R}^p$ to the
space of Schwartz functions on $\mathbb{R}^p \times \tilde{L}_\mu = \mathbb{R}^p \times \mathbb{Z}^q$. Denote it by $H$. If $x \in L_\theta = W^*_\mu \oplus Y^*_\mu$ we denote by $x_W$ the projection of $x$ on $W^*_\mu$ and by $x_Y$ the projection of $x$ on $Y^*_\mu$ (obviously $x = x_W + x_Y$). We define the action of $\nabla_x$ on an element $f(z, a) \in H$, where $z \in \mathbb{R}^p$ and $a \in \tilde{L}_\mu$, as follows

$$(\nabla_x(f))(z, a) = (\nabla_{x_W}(f))(z, a) + 2\pi i \langle x_Y, a \rangle f(z, a), \quad (10)$$
where the action of \( \nabla_{xW} \) is the same as above (only along \( z \)'s). Notice that the operators \( \nabla_x, x \in L_\theta \) satisfy the commutation relations

\[
[\nabla_x, \nabla_y] = [\nabla_{xW}, \nabla_{yW}] = F(xW, yW) = F(x, y), \quad x, y \in L_\theta,
\]

since \( \nabla_{xy} \) (recall that \( (\nabla_{xy}(f))(z, a) = 2\pi i (x_Y, a) f(z, a) \)) commutes with \( \nabla_y \) for any \( y \in L_\theta \).

Thus, we constructed operators \( \nabla_x, x \in L_\theta \) which satisfy the desired commutation relations. Next, we will construct operators acting on the space \( H \) which generate a non-commutative torus \( \widetilde{A}_{\theta} \) such that

1. \( \nabla \) is an \( \widetilde{A}_{\theta} \) connection
2. \( \theta - \tilde{\theta} \) is an element of \( \Lambda^2 W^* \).

4.1.2 Construction of operators satisfying conditions \([11]\).

Let us choose a basis \( \beta_1, \ldots, \beta_{2p} \) of \( L_\mu \) and a basis \( \beta_{2p+1}, \ldots, \beta_{2p+q} \) of \( \widetilde{L}_\mu \). We will construct operators \( \widetilde{V}_i, 1 \leq i \leq 2p + q \) acting on \( H \) which generate a non-commutative torus \( \widetilde{A}_{\theta} \) such that

\[
\begin{align*}
\text{first} \quad & \nabla \text{ is an } \widetilde{A}_{\theta} \text{ connection} \\
\text{second} \quad & \theta - \tilde{\theta} \text{ is an element of } \Lambda^2 W^*.
\end{align*}
\]

**Lemma 4.1** For \( 1 \leq i \leq 2p \) there exists an operator \( \widetilde{V}_i \) acting on \( H \) such that

1. \( (\widetilde{V}_i(f))(z, a) = e^{2\pi i \chi_i(z)} f(z + y_i, a), \) where \( z \in \mathbb{R}^p, \ a \in \widetilde{L}_\mu, \)
   for some \( y_i \in \mathbb{R}^p \) and some linear function \( \chi_i \in (\mathbb{R}^p)^*; \)
2. \( [\nabla_x, \widetilde{V}_i] = 2\pi i (x, \beta_i) \widetilde{V}_i, \) for \( x \in L_\theta. \)

**Proof:** Let us introduce an operator \( W(y, \chi) \), where \( y \in \mathbb{R}^p \) and \( \chi \in (\mathbb{R}^p)^* \)

\[
(W(y, \chi)f)(z, a) = e^{2\pi i \chi(z)} f(z + y, a).
\]

A straightforward calculation shows that \( [\nabla_x, W(y, \chi)]W(y, \chi)^{-1} \) is an operator of multiplication by a real number and moreover we obtain a non-degenerate pairing between the spaces \( W^*_\mu \) and \( \mathbb{R}^p \oplus (\mathbb{R}^p)^* \). Thus an choosing appropriate element \( y_i \in \mathbb{R}^p \) and \( \chi_i \in (\mathbb{R}^p)^* \) we can put \( \widetilde{V}_i = W(y_i, \chi_i). \)

Q.E.D.

We define the operators \( \widetilde{V}_i \) for \( 1 \leq i \leq 2p \) as in the above lemma. We define the operators \( \widetilde{V}_i \) for \( 2p + 1 \leq i \leq 2p + q \) acting on \( H \) by the formula

\[
(\widetilde{V}_i f)(z, a) = f(z, a - \beta_i).
\]
Lemma 4.2 For any $1 \leq i \leq n = 2p + q$, and any $x \in L_\theta$ we have

$$[\nabla_x, \tilde{V}_i] = 2\pi i \langle x, \beta_i \rangle \tilde{V}_i.$$  \hfill (12)

**Proof:** For $i \leq 2p$ formula (12) follows from Lemma 4.1. For $i > 2p$ formula (12) follows from an easy straightforward calculation.

Q.E.D.

It is easy to check that the operators $\tilde{V}_i$ are generators of some non-commutative torus. Moreover, these operators satisfy the first condition in (11) but they do not satisfy the second condition. To remedy this we will modify the operators $\tilde{V}_i$ replacing them with operators $V_i = e^{2\pi i l_i(\cdot)} \tilde{V}_i$.

If $l \in Y^*_\mu$ then the operator $e^{2\pi i l(\cdot)} \tilde{V}_i$ acts on $H$ by the formula

$$(e^{2\pi i l(\cdot)} \tilde{V}_i(f))(z,a) = e^{2\pi i l(a)} (\tilde{V}_i(f))(z,a).$$

Moreover, we have

$$[\nabla_x, e^{2\pi i l(\cdot)} \tilde{V}_i] = 2\pi i \langle x, \beta_i \rangle e^{2\pi i l(\cdot)} \tilde{V}_i$$

which follows from an easy straightforward calculation (since the operator $e^{2\pi i l(\cdot)}$ commutes with the operators $\nabla_x$, $x \in L_\theta$).

**Proposition 4.1** For $1 \leq i \leq 2p + q$ there exists a linear function $l_i \in Y^*_\mu$ on $Y^*_\mu$ such that

if we define $V_i = e^{2\pi i l_i(\cdot)} \tilde{V}_i$ then

$$V_iV_j = e^{2\pi i \sigma_{ij}} V_jV_i; \hfill (13)$$

and $\theta - \tilde{\theta}$ is an element of $\Lambda^2 W^*_\mu$.

**Proof:** First, it is easy to see that there exists a 2-form $\sigma \in \Lambda^2 L_\theta$ such that

$$\tilde{V}_i \tilde{V}_j = e^{2\pi i \sigma_{ij}} \tilde{V}_j \tilde{V}_i.$$

An easy calculation shows that the operator $e^{2\pi i l(\cdot)}$ commutes with the operators $\tilde{V}_i$ for $i \leq 2p$. If $i > 2p$ then we have

$$\tilde{V}_i \circ e^{2\pi i l(\cdot)} = e^{-2\pi i l(\beta_i)} (e^{2\pi i l(\cdot)} \circ \tilde{V}_i).$$

This gives us that

if $i, j \leq 2p$ then

$$V_iV_j = e^{2\pi i \sigma_{ij}} V_jV_i; \hfill (14)$$

16
if $i \leq 2p$ and $j > 2p$ then

$$V_i V_j = e^{2\pi i (\sigma_{ij} + l_i(\beta_j))} V_j V_i;$$

(15)

and if $i, j > 2p$ then

$$V_i V_j = e^{2\pi i (\sigma_{ij} + l_i(\beta_j) - l_j(\beta_i))} V_j V_i.$$  

(16)

For $1 \leq i \leq 2p$ we define $l_i \in Y_\mu^*$ by the formula

$$l_i(\beta_j) = \theta(\beta_i, \beta_j) - \sigma_{ij}$$
on the basis $\{\beta_j\}, j > 2p$ of $Y_\mu$. For $2p < i \leq 2p + q$ we define $l_i \in Y_\mu^*$ by the formula

$$l_i(\beta_j) = \frac{1}{2}(\theta(\beta_i, \beta_j) - \sigma_{ij})$$on the basis $\{\beta_j\}, j > 2p$ of $Y_\mu$.

Equations (14), (15), and (16) show that

$$V_i V_j = e^{2\pi i \theta(\beta_i, \beta_j)} V_j V_i$$if either $i$ or $j$ greater then $2p$ and

$$V_i V_j = e^{2\pi i \sigma_{ij}} V_j V_i$$if $i, j \leq 2p$. Thus we constructed the linear functions $l_i \in Y_\mu^*$ such that the conditions (13) are satisfied.

Q.E.D.

We define the operators $V_i$ as in the above Lemma. We easily see that the operators $V_i$ generate a non-commutative torus $A_{\tilde{\theta}}$, where $\tilde{\theta}(\beta_i, \beta_j) = \sigma_{ij}$ if both $i, j \leq 2p$ and $\tilde{\theta}(\beta_i, \beta_j) = \theta(\beta_i, \beta_j)$ otherwise.

Thus, the operators $V_i$ satisfy the condition (11).

4.1.3 Construction of a projective $A_{\tilde{\theta}}$ module.

Now we will identify our construction with the construction given in \[Rf 1\].

Let $G$ be a central extension of the abelian group $\mathbb{IR}^p \times \widetilde{L}_\mu \times (\mathbb{IR}^p)^* \times (\widetilde{Y}_\mu/L_\mu^*)$ given by the natural pairing between $\mathbb{IR}^p \times \widetilde{L}_\mu$ and $(\mathbb{IR}^p)^* \times (\widetilde{Y}_\mu/L_\mu^*)$. We see that $G$ is a Heisenberg group and it acts naturally on $H$. We denote this representation by $\rho$. Moreover, for each $V_i$ there exists a unique element
$g_i \in G$ such that $\rho(g_i) = V_i$. One can easily recognize the construction of elementary modules over non-commutative tori in M. Rieffel’s paper [RF].

Thus, choosing an appropriate space of functions on $\mathbb{R}^p \times L_\mu$ we get a projective $\mathcal{A}_\theta$-module $\tilde{E}$ with constant curvature connection $\nabla$ such that

1. the curvature of $\nabla$ is $F$;
2. $\theta - \tilde{\theta}$ is an element of $\Lambda^2 \mathcal{W}_\mu^*$.

Next, we would like to find explicitly the class $[\tilde{E}]$ in $K_0(\mathcal{A}_\theta)$. Note, that in our construction of module $\tilde{E}$ we canonically identified the space $L_\theta$ with the space $L_{\tilde{\theta}}$. Thus, we can think about $[\tilde{E}]$ as an integral element of $\Lambda^{\text{even}} \mathcal{W}_\mu^*$.

Let us remind that in paper [RF] M. Rieffel introduced a linear map $\tilde{T} : L_{\tilde{\theta}} \to \mathbb{R}^p \times \mathbb{R}^q \times (\mathbb{R}^p)^*$. In our notation $L_{\tilde{\theta}}$ is canonically identified with $L_\theta = V = W_\mu \oplus Y_\mu$ and $\mathbb{R}^q$ with $Y_\mu$. Thus, in our terms we have a linear map $\tilde{T} : W_\mu \oplus Y_\mu\to \mathbb{R}^p \times Y_\mu \times (\mathbb{R}^p)^* = \mathbb{R}^p \times (\mathbb{R}^p)^* \times Y_\mu$. It is easy to see from the explicit construction of the operators $V_i$ that $\tilde{T}$ maps $W_\mu$ to $\mathbb{R}^p \times (\mathbb{R}^p)^*$, and $Y_\mu$ to $Y_\mu$. Moreover the restriction of $\tilde{T}$ on $Y_\mu$ is the identity map.

M. Rieffel found in [RF] that

$$[\tilde{E}] = d \prod_{j=1}^p \tilde{Y}_j \wedge \tilde{Y}_{j+p},$$

where $d = \det(\tilde{T})$ and

$$\tilde{Y}_j = \begin{cases} \tilde{T}^{-1}(\bar{e}_j) & \text{for } 1 \leq j \leq p \\ \tilde{T}^{-1}(e_{j-p}) & \text{for } p+1 \leq j \leq 2p, \end{cases}$$

where $\{e_j\}$ is a basis of $\mathbb{R}^p$ and $\{\bar{e}_j\}$ is the dual basis of $(\mathbb{R}^p)^*$.

Since $\tilde{T}$ is the identity map on $Y_\mu$ we see that

$$\det(\tilde{T}^{-1}) = \pm \frac{\Pi_{j=1}^p \tilde{Y}_j \wedge \tilde{Y}_{j+p}}{\alpha},$$

where $\alpha$ is the volume form on $W_\mu$ (see Proposition 2.1 for the definition of $\alpha$). Note, we put a $\pm$ sign because we do not want to specify precisely how to pick a volume form. The lattice $L_\mu$ specifies the volume form up to a sign.
Later it will be easy to make the right choice of the sign so that everything would agree with M. Rieffel’s paper \[Rf1\]. We get
\[
d = \det(\widetilde{T}) = 1 / \det(\widetilde{T}^{-1}) = \pm \frac{\alpha}{\prod_{j=1}^{p} y_j \wedge y_{j+p}}.
\]
Thus we obtain that
\[
[\widetilde{E}] = \pm \alpha. \quad (19)
\]

4.1.4 Construction of a projective $A_\theta$ module $E$.

From the above results and Proposition 3.1 we see that if we make the right choice of the sign (so that $[\widetilde{E}] = \alpha$) then
\[
N = \frac{\mu(2p)}{\alpha} \quad (20)
\]
is a positive integer. Moreover, we have
\[
d_{\widetilde{E}} e^{\frac{F}{2\pi i}} = e^{i(\theta)} \mu
\]
and
\[
d e^{\frac{F}{2\pi i}} = e^{i(\widetilde{\theta})} \alpha.
\]
Therefore,
\[
e^{i(\theta)} \mu = \left( \frac{d_{\widetilde{E}}}{d} \right) e^{i(\widetilde{\theta})} \alpha. \quad (21)
\]
From equations 21 and 20 we see that $\frac{d_{\widetilde{E}}}{d} = N$.

One can easily check that the conditions of Lemma 3.1 are satisfied. Therefore $N(\theta - \widetilde{\theta})$ is an integral element of $(W_{\mu})^* = X_{\mu}$. From Proposition 3.2 follows that there exists $N$-dimensional module $M$ over $A_{\theta - \widetilde{\theta}}$. Denote by
\[
E = \widetilde{E} \otimes M. \quad (22)
\]
From Proposition 5.4 and Theorem 5.6 in M. Rieffel’s paper \[Rf1\] it follows that $E$ is a projective module over $A_\theta$ (since $\theta = \widetilde{\theta} + (\theta - \widetilde{\theta})$) with constant curvature connection with the curvature given by formula
\[
\Omega = F \otimes \text{Id}_M = F
\]
and
\[
\text{ch}(E) = \text{dim}(M) \text{ch}(\widetilde{E}).
\]
Therefore we see that

\[ \text{ch}(E) = N \text{ch}(\tilde{E}) = N e^t(\tilde{\theta}) \alpha = N \left( \frac{d}{dE} \right) e^t(\theta) \mu = e^t(\theta) \mu. \]

Thus we constructed a projective \( \mathcal{A}_\theta \)-module \( E \) with constant curvature connection such that \([E] = \mu\). This finishes the proof of Theorem 1.1 Q.E.D.

**Acknowledgements.** We would like to express our deep gratitude to Dmitry Fuchs, Anatoly Konechny and Marc Rieffel for numerous fruitfull discussions.
