Abstract

Background

Forcibly displaced Myanmar nationals (FDMNs) or Rohingya refugees are one of the vulnerable groups suffering from different kinds of health problems but have been less reported yet. Therefore, the study was designed to delineate the health problems among FDMNs admitted to Cox's Bazar Medical College Hospital.

Methods

This hospital-based cross-sectional study was conducted at the Medicine ward, Cox's Bazar Medical College Hospital, for a six-month period following approval. Rohingya refugees who were admitted during the study period were approached for inclusion. Informed written consent was ensured prior to participation. A structured questionnaire was used during data collection. Collected information was recorded in case record form. A total of 290 subjects were interviewed. Analysis was performed using the statistical package for social science (SPSS) version 20.

Results

The mean age of the participants was 48.76±18.67 years (range: 16-91), with a clear male predominance (60.7%). Family size ranged 6-8. All of the participants reported at least one of the illnesses. Of all, 29.66% patients reported disease of the respiratory system, and 26.9% reported disease of the gastrointestinal disease and hepatobiliary system. Accidental injury or injury due to electrocution or thin falls or snake bites was present in 10.4% of the cases. Among the single most common diseases, COPD (20%) was the most frequently observed, and the rest of them were chronic liver disease (13.1%), pulmonary TB (5.5%), ischemic stroke (5.5%), CAP (4.1%), acute coronary syndrome (3.4%), thalassaemia (3.4%) and hepatocellular carcinoma (3.4%). Among the top 6 reported diseases, PTB was more common in elderly individuals (p=0.29). The disease pattern was similar across the sexes among the refugees except community acquisition pneumonia (CAP), which was commonly observed among males (p=.004). Considering different age groups, genitourinary problems were more common in males aged >60 years, and rheumatology and musculoskeletal problems were equally affected in females aged between 40-60 years.

Conclusion

COPD, CLD and CAP were the most prevalent diseases in FDMN patients who attended the medicine ward of Cox's Bazar Medical College Hospital. Further exploration is warranted before any policy making and comprehensive plan.
Introduction

Forcibly displaced Myanmar nationals (FDMNs), commonly known as Rohingyas, are an ethnic, linguistic and religious minority group of northern Rakhine state (NRS) of Myanmar [1]. Clashes and conflicts resulted in displacement in bordering areas of Bangladesh [2]. Although it is not a new phenomenon in the world, approximately 71 million people have been displaced globally because of persecution, conflicts, environmental and other disasters, and among them, 25.9 million are refugees [3]. In 1991-1992, more than 250,000 Rohingya refugees fled persecution in the Union of Myanmar and arrived in Bangladesh [4]. More recently, in August 2017, a large displacement occurred, and an estimated 624 000 people fled from Rakhine State to Bangladesh, increasing the total Rohingya population by over 9,00,000 (only in Cox’s bazar district) [5].

Despite these reasons, this vulnerable population lives in temporary camps and is completely dependent on outside support from the United Nations (UN), the Government of Bangladesh (GOB) and numerous nongovernmental organizations (NGOs) [6]. Despite the collaborative assistance of different national and multinational organizations, the overall general health status of refugees is scarcely reported [7]. They suffered from different kinds of communicable and noncommunicable diseases. Accidents and/or injuries are also common in their camps.[6, 8] Lack of provision of adequate food, water, shelter, sanitation, and the apparently very low level of immunization, creating a perfect storm for the public health situation, were thought to be predictors of their health problems [6, 9]. More recently, a diphtheria outbreak resulted in 38 deaths, and more than 5800 suspected cases of diphtheria were reported as of February 2018. There have also been reports on respiratory problems and skin diseases among refugees, with 10,846 and 3,422 cases, respectively [10].

There are approximately 124 national and international health partners providing services through 169 health facilities (including 7 hospitals) [2]. Approximately 1.2 million people are estimated to be in need of health assistance, including both newly arriving individuals and their host communities [11, 12]. Irrespective of all health measures, no comprehensive reports have been observed to identify the health problems of this vulnerable population. However, understanding their health problems and proper strategic action plans are required to address the issue both by Govt. and Internationally. For this reason, the study was planned to assess health problems among FDMNs attending the medicine department of Cox’s bazar Medical College Hospital, Bangladesh.

Materials And Methods

Study design, study site and selection of the patients: This hospital-based cross-sectional study was conducted in the Medicine ward, Cox’s Bazar Medical College Hospital, for a period of six months. Formal ethical approval was sought prior to conducting the study. Cox’s Bazar Medical College Hospital is a tertiary care hospital in Cox’s Bazar, Bangladesh, which received patients from around Cox’s Bazar district irrespective of the social context of the local and FDMN people. The FDMN patients admitted to the medicine ward suffering from any health conditions were primarily targeted for the study population.
FDMN patients aged ≥18 years, admitted to the Medicine ward of Cox’s Bazar Medical College Hospital and willing to participate in the study were included in the study. The study was intended to report the disease patterns among FDMN patients. FDMNs who were under-aged, pregnant women and not willing to participate were excluded from the study. Moreover, failure to reach final diagnosis was also considered a criterion of exclusion. Data were collected focusing on their demographic profile, and clinical problems compelled them for admission to the study site.

Data collection methods: Data were collected either from patients or their attendants through direct interviews by a semi-structured questionnaire. In all cases, informed written consent was ensured before participation. A preformed questionnaire was used for data collection. The questionnaire consists of four parts: i) a brief introduction & consent statement, ii) demographic profile, and iii) detailed history along with clinical and radiological information of the participants and confirmed diagnosis of the patients. Initially, pretesting of the questionnaire was performed among 10 random participants, and the experience of the piloting was used to make a final adjustment before the final assessment. Hence, a total of 290 interview notes were finally included in the study. The date of disease onset was defined as the day when the symptom was noticed. The clinical parameters included age, sex, family member, time and place from illness onset to hospital admission, comorbidities (systemic hypertension, diabetes mellitus, heart disease, chronic obstructive pulmonary disease, etc.), symptoms, and clinical signs were collected through the questionnaire and were evaluated by trained physicians. General and systematic physical examinations were performed in all patients, including necessary investigations. Mental health was assessed by an expert psychiatrist and diagnosed accordingly. As the study was focused on the disease pattern, for that reason, the final diagnosis was collected in detail from the patient as well as medical reports. All systematic diseases, infectious diseases and accidental diseases were included and diagnosed in this study. All collected data were recorded in a structured case record form and later accumulated and compiled.

Ethical statement: All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional (Cox’s Bazar Medical College Hospital) and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. For this type of study, formal consent was ensured. Ethical measures were taken throughout the study period to maintain a high standard of confidentiality and anonymity of the participants.

Data acquisition and statistical analysis: All of the collected data were entered into a spreadsheet of the statistical software and analyzed with SPSS 20. Descriptive statistics were used during analysis, where continuous variables were expressed as the mean±standard deviation and categorical variables were expressed as count (percentage). To determine the association, the chi-square test was used. All results were analyzed with 95% CIs, and a p value <0.05 was considered statistically significant.

Results
We collected data from 290 individuals who were admitted with various health problems. The mean age of the participants was 48.76±18.67 years (range: 16-91), and the majority were aged >60 years (n=105; 36.2%). Of all, 60.7% were male, and the majority had family members ranging from 6-8 (86.2%). Approximately 67% had a previous history of smoking habits. More are described in Table 1.

All of the participants reported at least one of the illnesses of interest. Of the surveyed respondents, 29.66% individuals reported disease of the respiratory system, and 26.9% reported disease of the gastrointestinal disease and hepatobiliary system. COPD (20%) ranked at the top of the disease identified in this study. More are described in Table 2.

Among the top 6 reported diseases, PTB was linked with age difference and was more common in elderly individuals (p=0.29). In contrast, diseases of the rheumatology and musculoskeletal system have a propensity to occur in people aged >60 years (p<0.001). More are illustrated in Table 3.

The disease pattern was similar across the sexes among the refugees except community acquisition pneumonia (CAP), which was commonly observed among males (p=.004) (Table 4).

Man with higher chronological age (>60 y) suffer more from genito-urinary problems, while rheumatology and musculoskeletal problems are commonly encountered in people aged 40-60 years irrespective of gender. For more details, see Table 5.

Discussion

Forcibly displaced Myanmar nationals (FDMNs) to Bangladesh are currently the world’s largest and most densely populated refugee population [13], causing human suffering on a catastrophic scale. Due to the increasing number of Rohingya refugees and their congested living conditions in camps, there has been an overwhelming increase in their health risks. Against this backdrop, it is important to ensure health services for the Rohingya population, and to do so, knowing about their current health status is imperative because without this information, equal and equitable health service provision, as well as appropriate resource allocation, is not possible. In addition, failure to provide adequate health service and thus to maintain the sound health of Rohingya refugees might adversely affect the health status of Bangladeshi people. Therefore, we conducted this study with the aim of understanding the current health status of FDMNs in Bangladesh. Total 290 patients were included. The majority of the patients were younger than 60 years, with a mean age of 49 years (range: 16-91). A study by Masud et al. on the health problems and health care seeking behavior of Rohingya refugees found an almost similar age distribution, with a mean of 46 years, and the majority of refugees were 19-59 years of age [4]. However, several studies found different patterns of age distribution in our findings, which might be due to the larger sample size and inclusion of child groups in the population [14, 15].

In this study, we found a male predominance (60.7%) compared to females (39.3%). This result is incompatible with other studies where female sex was predominantly higher than male sex [4, 14, 15]. The reason behind the similarities is probably the effect of the study site, as this study was confined to
the medicine ward in Cox’s bazar Medical College Hospital, where gynae and obstetrical services and surgical services were not provided. Moreover, as this study excluded child groups, a significant portion of females, especially children, was not included in these findings.

In our study, the majority of patients suffered from respiratory system diseases, followed in decreasing order by GIT and hepato-biliary system, cardio-vascular system, nervous system, malignancy and genito-urinary system. Among the most prevalent diseases, COPD was ranked on top, followed by chronic liver disease, pulmonary TB, ischemic stroke, CAP, acute coronary syndrome, thalassaemia and hepatocellular carcinoma. In addition, we found that 7.6% of patients had HTN and 5.5% had a history of DM. A similar study performed by Masud AA et al. found that urinary tract infection (UTI) was the leading individual health problem, followed by hypertension, respiratory tract infection, nutrition deficiency and diabetes mellitus [4]. The overall scenario was slightly different from our study, as that study was conducted at a primary care center and our study was conducted in a tertiary care setting. However, there is a scarcity of evidence on disease patterns among Rohingya refugees in Bangladesh to compare our study findings, although the high prevalence of noncommunicable diseases (NCDs) such as COPD, cardiovascular diseases, chronic liver diseases, diabetes, hypertension, and malignancy among adults in humanitarian settings across the globe is comparable to our findings [16–19]. These findings might be explained by the high exposure of the refugee population to different behavioral and environmental risk factors for developing NCDs [20]. However, prevention and early detection of NCDs are undoubtedly more cost-effective than managing the later stages of disease, as increasing severity and associated complications of NCDs concurrently increase morbidity and mortality for refugees [21].

Doctors of the world have found a high prevalence of mental health problems and psychological distress in migrant and refugee populations, including posttraumatic stress disorder, depression, anxiety, sleep disturbance, substance misuse and somatization [22], as a consequence of violence, and migration-related factors, such as adjusting to a different environment in a new country [15]. In this study, we found only 4 patients (1.4%) with psychiatric disorders, specifically schizophrenia, which might be because only referred cases of mental disorders were admitted to the medicine ward and included as our study patients.

In addition, gynecological and obstetric services and the treatment and management of sexually transmitted diseases (STDs) and HIV/AIDS are essential to address the needs of populations living in camp settlements [5]. A report published in 2017 stated that one in seven Rohingya women in Northern Rakhine State had undergone at least one unskilled abortion under unhygienic conditions [23]. Thus, gynecological and obstetric diseases might be common among female FDMNs. However, data on sexual violence and female reproductive diseases were not available in our study, as our study site was confined to the medicine unit only and did not include gynecology wards.

On the whole, community health workers need to be effectively trained to ensure adequate health promotion. Welfare organizations need to pay more attention to the collection and dissemination of data. As refugees, their condition has been aggravated because of limited financial aid and overcrowded
unhealthy living conditions in settlements and camps. All of these factors will exacerbate their access to health care services, predisposing them to numerous health risks and increasing the chance of disease outbreaks. Thus, along with the government, private sectors and international communities must collaborate to assist refugees in their dire condition to improve their health status [14].

**Limitations:** The study has several limitations, including a small sample size, and the study was only confined to cases observed in the medicine department. Hence, it may not be reflective of actual health problems among the refugee lived in Bangladesh.

**Conclusion**

The Rohingya population mostly suffers from COPD, CLD and CAP. Respiratory health problems and gastrointestinal problems were the predominant reasons for hospital admission. With few exceptions, the disease pattern was similar across different age groups and genders.

### Table 4. Pattern of diseases according to sex difference (n=290)

| Diseases** | Age group | p value* |
|------------|-----------|----------|
|            | <40 years (N=103) | 40 to 60 years (N=82) | >60 years (N=105) |
| n (%)      | n (%)      | n (%)    |

**Top 6 Diseases**

- **COPD**
  - <40 years: 25 (24.3)
  - 40 to 60 years: 14 (17.1)
  - >60 years: 19 (18.1)
  - p value: 0.396

- **CLD**
  - <40 years: 20 (19.4)
  - 40 to 60 years: 8 (9.8)
  - >60 years: 10 (9.5)
  - p value: 0.061

- **CAP**
  - <40 years: 2 (1.9)
  - 40 to 60 years: 6 (7.3)
  - >60 years: 4 (3.8)
  - p value: 0.185

- **PTB**
  - <40 years: 2 (1.9)
  - 40 to 60 years: 4 (4.9)
  - >60 years: 11 (10.5)
  - p value: 0.029

- **Acute coronary syndrome**
  - <40 years: 4 (3.9)
  - 40 to 60 years: 2 (2.4)
  - >60 years: 4 (3.8)
  - p value: 0.839

- **Ischemic Stroke**
  - <40 years: 4 (3.9)
  - 40 to 60 years: 4 (4.9)
  - >60 years: 8 (7.6)
  - p value: 0.477

**Systems**

- **Cardiovascular**
  - <40 years: 10 (9.7)
  - 40 to 60 years: 4 (4.9)
  - >60 years: 10 (9.5)
  - p value: 0.419

- **Respiratory**
  - <40 years: 29 (28.2)
  - 40 to 60 years: 24 (29.3)
  - >60 years: 33 (31.4)
  - p value: 0.871

- **GIT and HBS**
  - <40 years: 33 (32)
  - 40 to 60 years: 18 (22)
  - >60 years: 27 (25.7)
  - p value: 0.289

- **Nervous**
  - <40 years: 6 (5.8)
  - 40 to 60 years: 6 (7.3)
  - >60 years: 8 (7.6)
  - p value: 0.864

- **Endocrine**
  - <40 years: 3 (2.9)
  - 40 to 60 years: 2 (2.4)
  - >60 years: 7 (6.7)
  - p value: 0.262

- **Genito-urinary**
  - <40 years: 2 (1.9)
  - 40 to 60 years: 0
  - >60 years: 6 (5.7)
  - p value: 0.050

- **Infection**
  - <40 years: 2 (1.9)
  - 40 to 60 years: 4 (4.9)
  - >60 years: 4 (3.8)
  - p value: 0.536

- **Malignancy**
