LOW DEGREE HODGE THEORY FOR KLT VARIETIES

MARTIN SCHWALD

Abstract. If $X$ is a complex projective variety with klt singularities, then the mixed Hodge structures on the first two singular cohomology groups are pure. We describe the pieces of the Hodge decomposition in terms of reflexive differential forms. Applications include a Lefschetz $(1,1)$ Theorem and a weak analogue of the Hodge-Riemann bilinear relations for klt varieties.

1. Introduction

1.1. Main results. For a singular, complex projective variety $X$, Deligne constructed mixed Hodge structures on the singular cohomology groups $H^p(X, \mathbb{C})$, [Del71]. Kirschner showed that the Hodge structure on $H^2(X, \mathbb{C})$ is pure when $X$ has rational singularities, [Kir15, Corollary B.2.8]. When $X$ is klt, we describe the relevant pieces of the Hodge decomposition in terms of reflexive differential forms $\Omega^p_X$, the definition of which we recall in 2.1.

Theorem 1 (Structure of $H^1(X, \mathbb{C})$ and $H^2(X, \mathbb{C})$, see Theorem 7 for details). If $X$ is a complex projective variety with at most klt singularities, then for $p = 1, 2$ the Hodge structure $H^p(X, \mathbb{C})$ is pure of weight $p$ and there are canonical isomorphisms

$$\kappa_p^0 : H^{p,0}(X) \rightarrow H^0(X, \Omega^p_X)$$

and

$$\kappa_0^p : H^{0,p}(X) \rightarrow H^p(X, \mathcal{O}_X).$$

We give two applications of this result. In Theorem 8 we prove a Lefschetz $(1,1)$ Theorem for the $H^{1,1}(X)$ part. This means that the integral points in $H^{1,1}(X)$ are precisely the first Chern classes of line bundles on $X$. Furthermore, we prove in

Corollary 10 an analogue of the Hodge-Riemann bilinear relations for klt varieties, in the special case where only forms of degree one and two are involved.

1.2. Further applications to symplectic varieties. In a further paper we apply the results found here to holomorphic symplectic varieties, which automatically have canonical singularities. There we show that the generalized Beauville-Bogomolov form on an irreducible symplectic variety $X$ has the index $(3,0,b_2(X) - 3)$, like in the smooth case. As a corollary, every non-trivial fibration of an irreducible symplectic variety $X$ onto a normal, complex projective variety $B$ is up to Stein factorization a Lagrangian fibration with $\dim B = \frac{1}{2}\dim X$ and Picard number $\rho(B) = 1$.

1.3. Acknowledgement. The author wants to thank his supervisor Prof. Kebekus for his advice and many fruitful discussions.

2. Differential forms and Extension Theorem

2.1. Holomorphic, torsion-free and reflexive differential forms. Let $X$ be a complex variety, not necessarily irreducible. We denote the sheaf of Kähler differentials by $\Omega_{X,t}^\bullet$. The sheaves of holomorphic differential forms are the exterior powers $\Omega_{X,t}^p := \Lambda^p \Omega_{X,t}^1$ with the convention $\Omega_{X,t}^0 := \mathcal{O}_X$.

Denoting with $\mathcal{M}_X$ the sheaf of rational functions on $X$, we call the kernel of the natural map $\Omega_{X,t}^p \to \Omega_{X,t}^2 \otimes_{\mathcal{O}_X} \mathcal{M}_X$ the torsion subsheaf, $\text{tor} \Omega_{X,t}^p$. For the quotient we use the notation $\tilde{\Omega}_{X,t}^p := \Omega_{X,t}^p / \text{tor} \Omega_{X,t}^p$. By slight abuse of language, we call $\tilde{\Omega}_{X,t}^p$ the sheaf of torsion-free differential forms, cf. [Keb13, II].

Reflexive differential forms are holomorphic $p$-forms on the smooth locus $X_{\text{reg}}$ of a variety $X$. We notate the associated sheaf on $X$ as $\tilde{\Omega}_{X,t}^p$ and get

$$\Omega_{X,t}^p = (\Omega_{X,t}^p)^{**} = i_* \Omega_{X_{\text{reg}}}^p,$$

$$H^0(X, \Omega_{X,t}^p) \cong H^0(X_{\text{reg}}, \Omega_{X_{\text{reg}}}^p),$$

where $i : X_{\text{reg}} \hookrightarrow X$ is the inclusion. See [Har80] for a reference on reflexive sheaves and [GKKP11, II–III, KP16] for more information on reflexive differential forms.

2.2. Extension Theorem for reflexive differential forms. The extension theorem for differential forms [GKKP11, Theorem 1.4] shows that on a klt variety $X$ any reflexive form $\alpha \in H^0(X, \tilde{\Omega}_{X,t}^p)$ can be extended to any resolution of singularities. This allows us to construct pullbacks of reflexive forms along more general morphisms.

Theorem 2 (Pullbacks of reflexive forms, [Keb13, Theorem 1.3]). Let $f : Y \to X$ be a morphism between normal, complex projective varieties. Assume that there is a Weil divisor $D$ on $X$, such that $(X, D)$ is klt. Then there is a natural pullback morphism $f^* \tilde{\Omega}_{Y,t}^p \to \tilde{\Omega}_{X,t}^p$, consistent with the natural pullback of Kähler differentials on $X_{\text{reg}}$. \hfill $\square$

The consistency with the natural pullback of Kähler differentials is made precise in [Keb13, Theorem 5.2]. We will only consider the case when $f : Y \to X$ is surjective, for example a birational morphism. Then this consistency means that the pullback morphism $f^* \tilde{\Omega}_{Y,t}^p \to \tilde{\Omega}_{X,t}^p$ agrees with the usual pullback of Kähler differentials wherever $X$ and $Y$ are smooth. In other words, for every $\alpha \in H^0(Y, \tilde{\Omega}_{Y,t}^p)$ there is an $\tilde{\alpha} \in H^0(X, \tilde{\Omega}_{X,t}^p)$ that coincides with $f^*(\alpha|_{X_{\text{reg}}})$, seen as a Kähler differential on $Y_{\text{reg}} \cap f^{-1}(X_{\text{reg}})$. We call $\tilde{\alpha}$ an extension of $\alpha$ to $Y$. Pulling back reflexive forms is contravariantly functorial with respect to $f$. 

3. Hodge Theory for klt singularities

3.1. Cohomology of fibers. As a preparation for the proof of Theorem 1 we mention a consequence of a triangulation theorem of Lojasiewicz. It is frequently used in the literature, but the author does not know of a convenient reference. Moreover, we will need results about differential forms on the fibers of a resolution of a variety with klt singularities.

**Theorem 3.** Let $\nu: \tilde{X} \to X$ be a resolution of a compact, complex variety $X$. Then every point $p \in X$ has a basis of analytical neighborhoods $(U_i)_i$, such that the fiber $E := \nu^{-1}(p)$ is a deformation retract of each $\nu^{-1}(U_i)$. Thus for any $k \in \mathbb{Z}$ the restrictions $H^k(\nu^{-1}(U_i), \mathbb{Z}) \mapsto H^k(E, \mathbb{Z})$ are isomorphisms and we get $(R^k\nu_*\mathbb{Z})_p \cong H^k(E, \mathbb{Z})$.

**Proof.** Consider any semi-analytic neighborhood $U$ of $p$ and $V := \nu^{-1}(U)$. Lojasiewicz’s result [Loj64, Theorem 4] applied to the semi-analytic subsets $E$ and $V$ of the smooth manifold $\tilde{X}$ gives a locally finite triangulation of $V$, such that $E$ is a subcomplex. Then [Har74, Proposition A.5] gives a deformation retraction from any sufficiently small analytical neighbourhood $V'$ of $E$ to the fiber $E$. As $\tilde{X}$ is compact, we can choose a basis of these neighbourhoods of the form $\nu^{-1}(U_i)$ with the $(U_i)$, a basis of analytical neighborhoods of $p$.

As deformation retractions are homotopies, we get $H^k(\nu^{-1}(U_i), \mathbb{Z}) \mapsto H^k(E, \mathbb{Z})$ for any $k \in \mathbb{Z}$. Recall from [Har74, Proposition III.8.1] that the stalks $(R^k\nu_*\mathbb{Z})_p$ can be calculated as $\lim_{\nu} H^k(\nu^{-1}(U), \mathbb{Z})$, where the limit is taken over all analytic neighborhoods $U$ of $p$, which gives $(R^k\nu_*\mathbb{Z})_p \cong H^k(E, \mathbb{Z})$. □

**Theorem 4** (Torsion-free differential forms on fibers, [Keb13, Theorem 4.1], [HM07]). Let $X$ be a complex variety with at most klt singularities. We take any resolution $\nu: \tilde{X} \to X$. Let $E$ be the reduction of a fiber of $\nu$. Then there are no global torsion-free differential forms on $E$. In other words $H^p(E, \Omega^*_E) = 0$ for $p > 0$. □

Previously, Namikawa proved in [Nam01, Lemma 1.2] a similar statement for $X$ with rational singularities, but only with the assumption that $E$ is an snc fiber. The proof of Theorem 4 uses that by [HM07] every fiber $E$ is rationally chain connected. Hence $E$ supports only torsion differential forms.

**Lemma 5.** Let $X$ be a complex projective klt variety. Consider a resolution $\nu: \tilde{X} \to X$ and $E$ the reduction of any fiber of $\nu$. Assume that $E$ has only smooth components. Then for every $p > 0$ the restriction $F^pH^p(\tilde{X}, \mathbb{C}) \to F^pH^p(E, \mathbb{C})$ is the zero map, where $F^p$ denotes the Hodge filtration.

**Proof.** Let $E = \bigcup_{i=1}^k E_i$ be the decomposition of $E$ into its smooth, irreducible components and denote $E^k := \bigcup_{i=1}^k E_i$ for all $k$. The restriction of singular cohomology classes $H^p(\tilde{X}, \mathbb{C}) \to H^p(E^k, \mathbb{C})$ is a morphism of mixed Hodge structures, which restricts to a morphism between the $F^p$-parts. To prove the Lemma we inductively show that $F^pH^p(\tilde{X}, \mathbb{C}) \to F^pH^p(E^k, \mathbb{C})$ is the zero map for any $k$.

**Proof** that $F^pH^p(\tilde{X}, \mathbb{C}) \to F^pH^p(E_i, \mathbb{C})$ is zero for all $i$. As $\tilde{X}$ and all components $E_i$ are smooth, we have $F^pH^p(\tilde{X}, \mathbb{C}) = H^p(\tilde{X}, \Omega^*_\tilde{X})$ and $F^pH^p(E_i, \mathbb{C}) = H^0(E_i, \Omega^*_E)$. Furthermore, all holomorphic p-forms on $\tilde{X}$ and on the $E_i$ are torsion-free. Hence we get by [Keb13, Proposition A.6] the following commutative diagram.
that the preimage $E \subset X$ has a singular component. We notate the preimage as $	ilde{X} \to X$, where $\tilde{X}$ is the locally closed subset corresponding to the locus of points $x \in X$ for which their reduced fiber $f^{-1}(x)_{\text{red}}$ has a singular component. We notate the preimage as $E(f) = f^{-1}(Z(f))$.

Starting with an arbitrary resolution $f: Y \to X$, we want to modify it to shrink $Z(f)$, until we eventually obtain $Z(f) = \emptyset$. For this we choose by [Kol07, Theorem 3.35] an embedded resolution $g: Y' \to Y$ of $E(f) \subset Y$ by blowing up smooth centers over $E(f)$. This is a birational morphism $g$ from a smooth variety $Y'$, such that the preimage $E := g^{-1}(E(f))$ is an snc divisor and $g$ is an isomorphism over $Y \setminus E(f)$.

\[\begin{array}{cccc}
H^0(\tilde{X}, \Omega^p_{\tilde{X}}) & \to & H^0(E, \Omega^p_E) & \to & H^0(E, \Omega^p_{E_1}) \\
\downarrow & & \downarrow & & \downarrow \\
H^0(\tilde{X}, \Omega^p_{\tilde{X}}) & \to & H^0(E, \Omega^p_E) & \to & H^0(E, \Omega^p_{E_1})
\end{array}\]

Here, the horizontal maps are restriction maps and the vertical maps quotient out torsion differential forms. By Theorem [4] we have $H^0(E, \Omega^p_E) = 0$, so $H^0(\tilde{X}, \Omega^p_{\tilde{X}}) \to H^0(E, \Omega^p_E)$ is the zero map.

**Proof.** Let $\nu: \tilde{X} \to X$ be any resolution of singularities. We write $\nu^*\Omega^p_X$ for the pushforward of the Hodge structure $\Omega^p_X$ to $\tilde{X}$, denoted by $\nu^*\Omega^p_X = \nu^*\Omega^p_{\tilde{X}}$. We use the standard Mayer-Vietoris sequence, [Hat02, page 203].

\[\cdots \to H^{p-1}(E^k \cap E_{k+1}, C) \to H^p(E^k \cup E_{k+1}, C) \to H^p(E^k, C) \oplus H^p(E_{k+1}, C) \to \cdots\]

This is an exact sequence of mixed Hodge structures, hence we can restrict it to the $F^p$-part of the Hodge filtration. We have $F^p H^{p-1}(E^k \cap E_{k+1}, C) = 0$ by the definition of the mixed Hodge structure on a complex projective variety. This gives us the inclusion $F^p H^p(E^k, C) \to F^p H^p(E^k, C) \oplus F^p H^p(E_{k+1}, C)$, which is, up to sign, the sum of the two restrictions $F^p H^p(E^k, C) \to F^p H^p(E^k, C)$ and $F^p H^p(E_{k+1}, C) \to F^p H^p(E_{k+1}, C)$. Hence we get the following commutative diagram.

\[\begin{array}{ccc}
F^p H^p(\tilde{X}, C) & \to & F^p H^p(E^k, C) \oplus F^p H^p(E_{k+1}, C) \\
0 & \uparrow & 0 \\
F^p H^p(\tilde{X}, C) & \to & F^p H^p(E^k, C) \oplus F^p H^p(E_{k+1}, C)
\end{array}\]

As the diagonal maps are zero by the induction hypothesis, the map $F^p H^p(\tilde{X}, C) \to F^p H^p(E^k, C)$ is also the zero map. This completes the proof. $\Box$

To make use of the preceding Lemma [5] we need to make sure that we can always find a resolution fulfilling the needed assumption on the fibers. This is a variation of the frequently used strong resolution of singularities from [Kol07, Theorem 3.35].

**Lemma 6** (Resolution of singularities with nice fibers). Let $X$ be a complex projective variety. Then there is a resolution of singularities $\nu: \tilde{X} \to X$, given as a sequence of blowups of smooth centers over the singular locus $X_{\text{sing}}$, such that the reduction of every fiber of $\nu$ has only smooth components.

**Proof.** Let $f: Y \to X$ be any resolution of singularities. We write $Z(f) \subset X$ for the Zariski closure of the locus of points $x \in X$, for which their reduced fiber $f^{-1}(x)_{\text{red}}$ has a singular component. We notate the preimage as $E(f) = f^{-1}(Z(f))$.

Starting with an arbitrary resolution $f: Y \to X$, we want to modify it to shrink $Z(f)$, until we eventually obtain $Z(f) = \emptyset$. For this we choose by [Kol07, Theorem 3.35] an embedded resolution $g: Y' \to Y$ of $E(f) \subset Y$ by blowing up smooth centers over $E(f)$. This is a birational morphism $g$ from a smooth variety $Y'$, such that the preimage $E := g^{-1}(E(f))$ is an snc divisor and $g$ is an isomorphism over $Y \setminus E(f)$. 

\[\begin{array}{cccc}
H^0(\tilde{X}, \Omega^p_{\tilde{X}}) & \to & H^0(E, \Omega^p_E) & \to & H^0(E, \Omega^p_{E_1}) \\
\downarrow & & \downarrow & & \downarrow \\
H^0(\tilde{X}, \Omega^p_{\tilde{X}}) & \to & H^0(E, \Omega^p_E) & \to & H^0(E, \Omega^p_{E_1})
\end{array}\]
We consider the resolution $f' = f \circ g$ of $X$. The fibers of $f'$ over points $x \in Z(f)$ are contained in the subvariety $E \subset Y'$. All irreducible components of $E$ are smooth by construction of $g$ and we denote them as $E_i$. Morphisms from smooth complex varieties are by [Har77, Corollary 10.7] generically smooth. Thus we find open subsets $U_i \subset Z(f)$ such that $f'|_{E_i}$ is smooth over $U_i$ and the intersection $\bigcap U_i$ is a non-empty open subset of $Z(f)$. Therefore the reduction of every fiber of $f'|_E$ over $\bigcap U_i$ has only smooth components. The reductions of fibers of $f'$ over points $x \in X \setminus Z(f)$ have smooth components by the assumptions on $f$ and $g$. Hence $Z(f')$ is a proper closed subset of $Z(f)$.

We can replace the resolution $(Y', f')$ by $(Y, f)$ and the constant sheaf $\mathcal{C}$ on $\tilde{X}$ by construction of $g$. By [Har77, Corollary 10.7] generically smooth. Thus we find open subsets $U_i \subset Z(f)$ such that $f'|_{U_i}$ is smooth over $U_i$ and the intersection $\bigcap U_i$ is a non-empty open subset of $Z(f)$. Therefore the reduction of every fiber of $f'|_E$ over $\bigcap U_i$ has only smooth components. The reductions of fibers of $f'$ over points $x \in X \setminus Z(f)$ have smooth components by the assumptions on $f$ and $g$. Hence $Z(f')$ is a proper closed subset of $Z(f)$.

We proceed in five steps:

1. Calculate the low degree terms of the Leray spectral sequence for $\nu$: $\tilde{X} \to X$ and the constant sheaf $\mathcal{C}$ on $\tilde{X}$.
2. Prove the bijectivity of $\nu^*: H^1(X, \mathcal{C}) \to H^1(\tilde{X}, \mathcal{C})$, the injectivity of $\nu^*: H^2(X, \mathcal{C}) \to H^2(\tilde{X}, \mathcal{C})$ and the purity of the Hodge structures on $H^1(X, \mathcal{C})$ and $H^2(X, \mathcal{C})$.
3. Prove the surjectivity of the restrictions $\nu^*|_{\tilde{X}}$ and $\nu^*|_{\tilde{X}}$ of the map $\nu^*: H^2(X, \mathcal{C}) \to H^2(\tilde{X}, \mathcal{C})$, assuming that all reductions of fibers of $\nu$ have only smooth components.
4. Prove the surjectivity of $\nu^*|_{\tilde{X}}$ and $\nu^*|_{\tilde{X}}$ in general.
5. Calculate $H^{p,0}(X)$, $H^{0,p}(X)$ and construct the canonical isomorphisms $\kappa_{p,0}$, $\kappa_{0,p}$ for $p = 1, 2$.

**Proof.** We proceed in five steps:

1. Calculate the low degree terms of the Leray spectral sequence for $\nu$: $\tilde{X} \to X$ and the constant sheaf $\mathcal{C}$ on $\tilde{X}$.
2. Prove the bijectivity of $\nu^*: H^1(X, \mathcal{C}) \to H^1(\tilde{X}, \mathcal{C})$, the injectivity of $\nu^*: H^2(X, \mathcal{C}) \to H^2(\tilde{X}, \mathcal{C})$ and the purity of the Hodge structures on $H^1(X, \mathcal{C})$ and $H^2(X, \mathcal{C})$.
3. Prove the surjectivity of the restrictions $\nu^*|_{\tilde{X}}$ and $\nu^*|_{\tilde{X}}$ of the map $\nu^*: H^2(X, \mathcal{C}) \to H^2(\tilde{X}, \mathcal{C})$, assuming that all reductions of fibers of $\nu$ have only smooth components.
4. Prove the surjectivity of $\nu^*|_{\tilde{X}}$ and $\nu^*|_{\tilde{X}}$ in general.
5. Calculate $H^{p,0}(X)$, $H^{0,p}(X)$ and construct the canonical isomorphisms $\kappa_{p,0}$, $\kappa_{0,p}$ for $p = 1, 2$.

**Step [I].** The Leray spectral sequence of the constant sheaf $\mathcal{C}$ on $\tilde{X}$ is

$$E^{pq}_2 := H^p(X, R^q\nu_*\mathcal{C}) \Rightarrow H^{p+q}(\tilde{X}, \mathcal{C}).$$
Pushing forward the exponential exact sequence gives the exact sequence
\[ \nu_* \mathcal{O}_X \xrightarrow{\exp} \nu_* \mathcal{O}_X^\times \xrightarrow{0} R^1 \nu_* \mathcal{Z} \to R^1 \nu^* \mathcal{O}_X^\times = 0. \]

As the fibers are connected, the first map is induced by the exponential map \( \mathcal{O}_X \to \mathcal{O}_X^\times \), which is surjective, so the second map is the zero map. This shows that \( R^1 \nu_* \mathcal{Z} \) injects into \( R^1 \nu_* \mathcal{O}_X^\times \) and hence has to vanish, as klt singularities are rational, \([\text{KM}98\text{, Theorem 5.22}]\). Therefore \( R^1 \nu_* \mathcal{C} = 0 \) and the first terms of the second page \((E_2, d_2)\) are:

\[
\begin{array}{cccccc}
E_2^{01} & \xrightarrow{d_2} & E_2^{11} & \xrightarrow{d_2} & E_2^{12} & \xrightarrow{d_2} & H^0(X, R^2 \nu_* \mathcal{C}) \\
E_2^{02} & \xrightarrow{d_2} & E_2^{21} & \xrightarrow{d_2} & E_2^{20} & \xrightarrow{d_2} & H^0(X, \mathcal{C}) \\
0 & & 0 & & 0 & & H^2(X, \mathcal{C})
\end{array}
\]

The entries \((0,0), (1,0), (2,0)\) and the second row degenerate at the second page. We see \( E_2^{02} \cong E_2^{02} = H^0(X, R^2 \nu_* \mathcal{C}) \) and the entry \((0,2)\) degenerates at the fourth page with \( E_2^{02} = \ker (d_3: E_2^{02} \to H^3(X, \mathcal{C})) \subset H^0(X, R^2 \nu_* \mathcal{C}) \), which shows \( H^2(\tilde{X}, \mathcal{C}) \cong H^2(X, \mathcal{C}) \oplus E_2^{02} \). This gives the following exact sequence.

\[
\begin{array}{rccc}
& 0 & \to & H^1(X, \mathcal{C}) \\
& \nu^* & \to & \tilde{H}^1(\tilde{X}, \mathcal{C}) \\
& & \xrightarrow{\pi_{01}} & H^0(X, R^1 \nu_* \mathcal{C}) \\
& & & \xrightarrow{d_2} \\
& & & \tilde{H}^2(\tilde{X}, \mathcal{C}) \\
& & \xrightarrow{\nu^*} & H^2(X, \mathcal{C}) \\
& & & \xrightarrow{\pi_{02}} & H^0(X, R^2 \nu_* \mathcal{C})
\end{array}
\]  

\[ (1) \]

**Step 2.** As \( H^0(X, R^1 \nu_* \mathcal{C}) \) vanishes, sequence \((1)\) shows that \( \nu^*: H^1(X, \mathcal{C}) \to \tilde{H}^1(\tilde{X}, \mathcal{C}) \) is an isomorphism and \( \nu^*: H^2(X, \mathcal{C}) \to H^2(\tilde{X}, \mathcal{C}) \) is injective. They are also morphisms of mixed Hodge structures, which by Deligne are always strict with respect to both filtrations, cf. \([\text{GS75\text{, Lemma 1.13}]\). Thus both maps \( \nu^* \) induce also in any weight monomorphisms of pure Hodge structures. As the mixed Hodge structure on \( \tilde{H}^0(\tilde{X}, \mathcal{C}) \) is pure of weight \( p \), the same is true for \( H^0(X, \mathcal{C}) \) for \( p = 1, 2 \).

**Step 3.** We want to prove that the restriction \( \nu_{20}: H^{2,0}(X) \to H^{2,0}(\tilde{X}) \) of \( \nu^*: H^2(X, \mathcal{C}) \to H^2(\tilde{X}, \mathcal{C}) \) is surjective. By the exact sequence \((1)\) it is enough to show that \( \pi_{02} \) is the zero map on the subspace \( H^{2,0}(\tilde{X}) = F^2 H^2(X, \mathcal{C}) \). First of all, to be able to apply Lemma \( 5 \) later, we assume that all reductions of fibers of \( \nu \) have only smooth components.

To calculate \( \pi_{02} \), we choose by Theorem 3 open coverings \( U = (U_i)_i \) of \( X \) and \( V := (V_i)_i := (\nu^{-1}(U_i))_i \) of \( \tilde{X} \), such that for each \( i \) we have \( H^0(U_i, R^2 \nu_* \mathcal{C}) = H^2(E_i, \mathcal{C}) \) for a fiber \( E_i \) of \( \nu \) over a point in \( U_i \). By choosing the \( U_i \) to be contractible and an acyclic covering of \( X \), we can calculate \( \pi_{02} \) via \( \check{\text{Cech}} \) cohomology as the following composition.

\[
\begin{array}{ccccccc}
\gamma & \xrightarrow{H^2(\tilde{X}, \mathcal{C})} & \xrightarrow{\pi_{02}} & H^0(X, R^2 \nu_* \mathcal{C}) \\
(\gamma|_{E_i})_i & \xrightarrow{\prod H^2(E_i, \mathcal{C})} & \xrightarrow{\sim} & \prod_i H^0(U_i, R^2 \nu_* \mathcal{C}) & \xrightarrow{i} & H^0(X, U, R^2 \nu_* \mathcal{C})
\end{array}
\]
By assumption, all components of the reduced fibers \((E_i)_{\text{red}}\) are smooth. As the restrictions \(H^2(\tilde X, \mathbb C) \to H^2(E_i, \mathbb C)\) are morphisms of Hodge structures, they restrict to maps \(F^2H^2(\tilde X, \mathbb C) \to F^2H^2(E_i, \mathbb C)\) that vanish by Lemma 5. We see that the restriction of \(\pi_{\text{red}}\) to \(H^{2,0}(\tilde X)\) factors through the zero map and hence is the zero map itself. We conclude that \(\nu_{\text{red}}\) is surjective. By Hodge symmetry the same holds for \(\nu_{\text{red}}\).

**Step (3).** We use Lemma 5 to blow up smooth centers over \(\tilde X\), until we get a \(\tilde \nu\): \(X' \to \tilde X\), where \(X'\) is smooth and the reductions of all fibers of \(\mu := \nu \circ \tilde \nu\): \(X' \to X\) have only smooth components.

By part (1) pulling back with \(\mu, \nu, \tilde \nu\) on the \(H^{2,0}\) parts gives injections

\[
\mu_{\text{red}}^* : H^{2,0}(X) \hookrightarrow H^{2,0}(\tilde X) \hookrightarrow \nu_{\text{red}}^* : H^{2,0}(\tilde X) \to H^{2,0}(X').
\]

The map \(\mu_{\text{red}}\) is surjective by part (3), hence also \(\nu_{\text{red}}\). The surjectivity of \(\nu_{\text{red}}\) follows analogously.

**Step (4).** As \(X\) is normal, we have \(\nu_* \mathcal O_{\tilde X} \cong \mathcal O_X\) by Zariski’s Main Theorem, [Har77, Corollary 11.4]. As klt singularities are rational, the Leray spectral sequence for \(\nu\): \(\tilde X \to X\) and \(\mathcal O_{\tilde X}\) degenerates on \(E_2\) with zeros away from the row \(E_2^{0,0} = H^0(X, \nu_* \mathcal O_{\tilde X})\). This gives us \(\nu^* : H^p(X, \mathcal O_{\tilde X}) \sim \rightarrow H^p(\tilde X, \mathcal O_{\tilde X})\) for all \(p\), cf. [Har77, III §18.1]. We also have the isomorphisms \(\text{ext} : H^p(X, \Omega_{\tilde X}^\nu) \sim \rightarrow H^p(\tilde X, \Omega_{\tilde X}^\nu)\) from the extension theorem and the Dolbeault isomorphisms \(\delta_{\nu} : H^p(\tilde X, \Omega_{\tilde X}^\nu) \sim \rightarrow H^{p,0}(\tilde X), \delta_{\nu} : H^p(\tilde X, \Omega_{\tilde X}^\nu) \sim \rightarrow H^{0,p}(\tilde X)\). Hence we can define for \(p = 1, 2\) canonical isomorphisms \(\kappa_{\nu} \) and \(\kappa_{\nu} \) as compositions of these isomorphisms.

3.3. **Lefschetz (1,1) Theorem for klt singularities.** The classical Lefschetz (1,1) Theorem is usually stated for smooth, complex projective varieties, see for example [GH94, page 163–164]. In [BS00, Theorem 1.1] there is a Lefschetz (1,1) Theorem for any normal, complex projective variety. We give a short proof of the theorem for klt varieties, where we do not need to work with mixed Hodge structures by Theorem 4.

**Theorem 8** (Lefschetz (1,1) Theorem for klt singularities). Let \(X\) be a complex projective variety with at most klt singularities. The integral points in \(H^{1,1}(X)\) are exactly the first Chern classes of line bundles on \(X\). In other words, for the canonical map \(\iota : H^2(X, \mathbb Z) \to H^2(X, \mathbb C)\) we get

\[
H^{1,1}(X) \cap \im \iota = \im (c_1 : \text{Pic}(X) \to H^2(X, \mathbb Z)).
\]

**Proof.** We take a resolution \(\nu : \tilde X \to X\) and consider the canonical maps \(\nu : H^2(X, \mathbb Z) \to H^2(X, \mathbb C), \tilde \nu : H^2(\tilde X, \mathbb Z) \to H^2(\tilde X, \mathbb C)\) that extend the scalars. As \(\nu^* : H^2(X, \mathbb C) \to H^2(\tilde X, \mathbb C)\) preserves the Hodge decomposition, we get for any class \(\alpha \in H^{1,1}(X) \cap \im \iota\) that \(\nu^* \alpha \in H^{1,1}(\tilde X) \cap \im \tilde \iota\). Using the classical Lefschetz (1,1)-Theorem, we can write \(\nu^* \alpha = c_1(\mathcal L)\) for a line bundle \(\mathcal L\) on \(\tilde X\).

Let \(F = \nu^{-1}(p)\) be the reduction of any fiber of \(\nu\). Using the commutativity of the diagrams

\[
\begin{array}{ccc}
\nu & : & \tilde X \\
\text{red} & : & \tilde X \\
\nu_{\text{red}} & : & \nu_{\text{red}}
\end{array}
\]
on germs, the left hand side has to be trivial as well. In other words, there is a

\[ \mathfrak{U} \]

of

\[ \mathfrak{2} \]

c

where the limits are taken over all \( \mathfrak{V} \)

the fibers. Consequently, the coherent sheaf \( \mathfrak{L} \)

by the first Chern class. Restricting germ in the stalks of these sheaves,

\[ \mathfrak{L} \]

the same transition functions as

\[ \mathfrak{c} \]

the exponential sequence yields an isomorphism \( \mathfrak{c} \)

because

\[ \mathfrak{j} \]

We will use this for our application in Section 3.5, the Hodge Riemann bilinear

relations on klt varieties. Then

\[ \mathfrak{H} \]

3.4. Integration of singular top classes. We briefly recall how integrating top

singular cohomology classes always makes sense on irreducible, compact, complex

varieties and show that it is compatible with pullbacks by bimeromorphic maps.

We use this for our application in Section 3.5, the Hodge Riemann bilinear relations on klt varieties.

First we consider a smooth, compact, \( n \)-dimensional, complex manifold \( X \) with

the canonical orientation given by the complex structure. Integrals over classes in

\[ \mathfrak{H}^{2n}(X, \mathbb{Z}) \] are defined by integrating their de Rham class over \( X \). This is a linear

map, which by Poincaré duality is given by taking the cap product with an element

[\mathfrak{X}] of \( \mathfrak{H}_{2n}(X, \mathbb{Z}) \). More precisely, [\mathfrak{X}] is the fundamental class of \( X \) induced by

the canonical orientation of \( X \), [GH94] page 60f].

In general, there is no de Rham isomorphism or Poincaré duality in the singular

case. However, these integrals are generalized by ensuring the existence of a canonical fundamental class.

Lemma 9 (Existence of fundamental classes). Let \( X \) be an \( n \)-dimensional, irreducible, compact, complex variety. Then \( \mathfrak{H}_{2n}(X, \mathbb{Z}) \) and \( \mathfrak{H}^{2n}(X, \mathbb{Z}) \) are both isomorphic to \( \mathbb{Z} \) and the cap product induces a perfect pairing

\[ \mathfrak{c}: \mathfrak{H}_{2n}(X, \mathbb{Z}) \times \mathfrak{H}^{2n}(X, \mathbb{Z}) \longrightarrow \mathfrak{H}_0(X, \mathbb{Z}) \cong \mathbb{Z} \]

\[ (\sigma, \phi) \longrightarrow \sigma \cap \phi \]
Proof. Recall that the underlying topological space of a complex variety admits a triangulation that endows it with the structure of a 2n-dimensional pseudomanifold, [GM80] 1.1. As $X$ is compact, only finitely many simplices are needed. Like in the smooth case, $H_{2n}(X, \mathbb{Z})$ and $H^{2n}(X, \mathbb{Z})$ of a closed pseudomanifold $X$ are always isomorphic to $\mathbb{Z}$ or 0, depending on the orientability of $X$, [STS0 24]. Using the complex structure on the smooth locus, all simplices can be canonically oriented coherently, such that $X$ is orientable. The class of the sum over all canonically oriented 2n-simplices generates $H_{2n}(X, \mathbb{Z})$. □

**Notation 10.** On an $n$-dimensional, irreducible, compact, complex variety $X$ we note the generator of $H_{2n}(X, \mathbb{Z})$ that is induced by the complex structure as $[X]$ and call it the canonical fundamental class of $X$.

**Definition 11** (Integration of top classes). Let $X$ be an $n$-dimensional, irreducible, compact, complex variety with canonical fundamental class $[X]$. The integrals over top singular cohomology classes on $X$ are defined as follows.

$$H^{2n}(X, \mathbb{C}) \xrightarrow{\sim} H_{0}(X, \mathbb{C}) \cong \mathbb{C}$$

$\alpha \mapsto \int_{X} \alpha := [X] \cap \alpha$

**Lemma 12** (Pullbacks of integrals). If $f : X \to Y$ is a bimeromorphic morphism of irreducible, compact, complex varieties, then $\int_{Y} \alpha = \int_{X} f^{*} \alpha$ for all $\alpha \in H^{2n}(Y, \mathbb{C})$.

**Proof.** Holomorphic maps induce $\mathbb{C}$-linear maps between the tangent spaces. Therefore $f$ is compatible with the complex orientation, $f_*[X] = [Y]$. We apply the projection formula for the cap product:

$$\int_{Y} \alpha = [Y] \cap \alpha = f_*[X] \cap \alpha = [X] \cap f^* \alpha = \int_{X} f^* \alpha. \quad \square$$

### 3.5. Hodge-Riemann bilinear relations

On an $n$-dimensional, compact Kähler manifold $(X, \omega)$ we have for any $k \in \{0, \ldots, n\}$ the Hodge-Riemann sesquilinear form

$$\psi_{X, \omega} : H^{k}(X, \mathbb{C}) \times H^{k}(X, \mathbb{C}) \to \mathbb{C}$$

$$(p, \cdot, q, \cdot) \mapsto ( -1)^{\frac{k(k+1)}{2}} \cdot \int_{X} p \wedge \bar{p} \wedge \omega^{n-k}$$

satisfying the property that for any $p, q \in \mathbb{N}_0$ with $p + q = k$ the form $i^{p-q} \cdot \psi_{X, \omega}$ is positive definite on the primitive part $H^{p,q}(X)_{P} := \{ v \in H^{p,q}(X) \mid v \wedge \omega^{n-k+1} = 0 \}$, [Huy05 Proposition 3.3.15]. In other words,

$$\forall v \in H^{p,q}(X)_{P} \setminus \{0\} : i^{p-q} \cdot \psi_{X, \omega}(v, v) > 0.$$  

These inequalities are called the Hodge-Riemann bilinear relations. The following Lemma 13 will allow us to deduce an analogue in the singular setting. We will apply this in Corollary 14 in the case of varieties with at most klt singularities.

**Lemma 13** (Local Hodge-Riemann bilinear relations). Let $(X, \omega)$ be a smooth, $n$-dimensional Kähler manifold with a closed $(p, q)$-form $\alpha$ and set $k := p + q$. If $\alpha \wedge \omega^{n-k+1} = 0$, then the form $i^{p-q} \cdot (-1)^{\frac{k(k+1)}{2}} \cdot \alpha \wedge \bar{\alpha} \wedge \omega^{n-k}$ is a positive volume form on the subset of $X$ where $\alpha$ does not vanish.

**Proof.** This can be checked by a calculation in local coordinates at any point $x \in X$, where $\alpha$ does not vanish, which is done in [Huy05 Corollary 1.2.36]. The case $k \leq 2$, which is actually the interesting case for us, can also be found explicitly in [GH94] pages 124–125). □
Notation 14 (Hodge-Riemann sesquilinear form). For every $n$-dimensional, irreducible, complex projective variety $X$ any ample class $a \in H^2(X, \mathbb{C})$ induces a sesquilinear form $\psi_{X,a}$, defined by
\[
\psi_{X,a}: H^k(X, \mathbb{C}) \times H^k(X, \mathbb{C}) \rightarrow \mathbb{C}
\]
\[
(\alpha \ , \ \beta) \mapsto (-1)^{k(k-1)/2} \int_X \alpha \cup \beta \cup a^{n-k}.
\]

Corollary 15 (Singular bilinear relations). Let $X$ be an $n$-dimensional, irreducible, complex projective variety with a resolution $\nu: \tilde{X} \rightarrow X$ and an ample class $a = c_1(\mathcal{O}_X(A)) \in H^2(X, \mathbb{C})$. Then the bilinear relation $i^{p-q} \cdot \psi_{X,a}(\alpha, \alpha) > 0$ holds for any class $\alpha \in H^p(X, \mathbb{C}) \setminus \{0\}$ with $\alpha \cup a^{n-k+1} = 0$ and $\nu^*a \in H^q(\tilde{X})$.

\[
\nu^*a \in H^p(\tilde{X}) \text{ is ample away from the exceptional locus of } \nu.
\]
