We study the low energy pion-hyperon interaction considering effective non-linear chiral invariant Lagrangians including pions, \( \rho \)-mesons, \( \sigma \)-mesons, hyperons and corresponding resonances. Then we calculate the \( S \) and \( P \)-wave phase-shifts, total cross sections, angular distributions and polarizations for the momentum in the center-of-mass frame up to \( k \approx 400 \) MeV. With these results we discuss the CP violation in the \( \Xi \to \Lambda \pi \) and \( \Omega \to \Xi \pi \) weak decays.

I. INTRODUCTION

Why should we study pion-hyperon (\( \pi Y \)) interaction? It is not hard to see that, due to their instability, it is not an easy task for an experimentalist to make beams of pions and hyperons, let them collide and study what happens in such collisions. As far as we know, no experimental data on \( \pi Y \) interaction are available. In such a situation, is there any practical interest, besides academic one, in theoretically studying these interactions?

In 1957, Okubo \cite{1} observed that the CP violation allows \( \Sigma \) and \( \bar{\Sigma} \) to have different branching ratios into conjugate channels. Pais \cite{2} extended this proposal also to \( \Lambda \) and \( \bar{\Lambda} \) decays. In these reactions, the final-state strong interaction between the decay products plays a very important role. The few studies on \( \pi Y \) interactions we could find in the literature \cite{3,4} are related to the \( \Xi \to \pi \Lambda \) decay, in which an independent estimate of the \( \pi \Lambda \) strong phase shifts is needed to correctly analyze the data and conclude about the CP violation. In these references, however, the results presented show some discrepancy among them, especially on \( \delta_S \), requiring a clarification. As for the other interactions, such as \( \pi \Sigma \) and \( \pi \Xi \), within our limited knowledge no study has ever been done.

Besides, we have a somewhat different motivation for the present study. It is by now well known that in high-energy proton-nucleus collisions, the inclusively produced hyperons appear usually polarized \cite{3,5}. Several models have been proposed to explain this phenomenon \cite{6,7}, which at least qualitatively, or even quantitatively, can account for the hyperon polarization. However, as for the anti-hyperons which are generally produced also with polarization \cite{3,5}, no one of these models are applicable, since all of them are based on some leading-particle effect in which the incident proton is transformed into a leading hyperon. \(^1\) In \cite{6}, it is proposed that at least part of the polarization is caused by the final-state interaction of (anti-)hyperon with the surrounding hot medium where it is produced during the collision of the incident objects. This mechanism would be the dominant one in the case of anti-hyperon polarization, since they cannot be produced as leading particles. In \cite{7}, this idea was put forward within a hydrodynamic model, by treating the interaction with the hot medium as given by an optical potential, reproducing all the qualitative features of the existing data. Evidently, it is desirable that, if possible, more realistic microscopic interaction be used instead of purely phenomenological potential with fitted parameters. Since pions are dominant in such a hot medium mentioned above, the microscopic interactions of our interest would be pion-hyperon (or more precisely pion-anti-hyperon) interactions. However, except for few results on \( \pi \Lambda \), we are not aware of any study on these interactions. So the main object of the present work is to study the low-energy (with respect to the surrounding medium) pion-hyperon interactions, aiming at a later computation of anti-hyperon polarization in high-energy hadron-nucleus collisions.

The plan of presentation is the following. We shall first explain, in the next section, the general strategy of treating the pion-hyperon interactions. Then, in sections III, IV and V, we apply it, respectively, to the \( \pi \Lambda \), \( \pi \Sigma \) and \( \pi \Xi \) cases. Phase shifts are calculated and from these the energy dependence of the total cross-section, the angular distribution and the polarization for each reaction are computed in these sections. Conclusions are drawn in section VI. Basic formalism is given in the appendix.

II. STRATEGY FOR THE STUDY OF THE PION-HYPERON INTERACTIONS

How could we proceed to study the low-energy \( \pi \bar{Y} \) interactions? First of all, due to the CPT invariance, it is enough to study the \( \pi Y \) interactions instead of the \( \pi \bar{Y} \) interactions. \(^1\) It should be mentioned that in a recent paper \cite{6}, a parametrization of \( \Lambda \) and \( \bar{\Lambda} \) polarization data has been carried out in terms of polarizing fragmentation functions.
ones. For instance, the $\bar{Y}$ polarization is obtained from the corresponding one for $Y$, just by changing the sign. Next, recall that unlike the $\pi Y$ ones, the low-energy $\pi N$ interaction is, for obvious reasons, very well studied since a long time. There is a large amount of experimental data, and also many models that reproduce them pretty well. Here, we shall consider a chiral-invariant effective Lagrangian model. In [22], such a Lagrangian was written in terms of $\pi$, $N$, $\rho$ and $\Delta$ fields as a sum of

$$\mathcal{L}_{N\pi N} = \frac{g}{2m} [\bar{N} \gamma_{\mu} \gamma_5 \tau N] \cdot \partial^\mu \tilde{\phi}$$  \tag{1}$$

$$\mathcal{L}_{N\pi \Delta} = g_\Delta \{ \bar{\Delta} \gamma_{\mu} \gamma_5 [\bar{N} \gamma_\tau M N] \cdot \partial^\mu \tilde{\phi} + H.c. \}$$ \tag{2}$$

$$\mathcal{L}_{N_\rho N} = \frac{g_\rho}{2} [\bar{N} \gamma_{\mu} \tau N] \cdot \partial^\mu \tilde{\phi} + \frac{g_\rho}{2} \{ \bar{N} \lbrace \mu_p - \mu_n \rbrace i\sigma_{\mu \nu} \tau N \} \cdot \partial^{\mu \nu} \tilde{\phi}$$  \tag{3}$$

$$\mathcal{L}_{\pi \rho \pi} = g_\rho \bar{\rho} \rho \cdot (\tilde{\phi} \times \phi) - \frac{g_\rho}{4m^2^\rho} (\partial_\mu \bar{\rho} \rho - \partial_\nu \bar{\rho} \rho)$$ \tag{4}$$

where $N$, $\Delta$, $\phi$, $\rho$ are the nucleon, delta, pion and rho fields with masses $m$, $m_\Delta$, $m_\pi$, and $m_\rho$, respectively, $\mu_p$ and $\mu_n$ are the proton and neutron magnetic moments, $M$ and $\tau$ are the isospin matrices and $Z$ is a parameter representing the possibility of the off-shell-$\Delta$ having spin 1/2. In addition, it also included a $\sigma$ term as a correction and parametrized it in a way we will show below.

Now, since $\pi \Lambda$, $\pi \Sigma$ and $\pi \Xi$ systems are similar to $\pi N$, we can make an analogy and use the same prescription explained above, adapting it appropriately. The $\Delta(1232)$ resonance plays a central role in the low-energy $\pi N$ interaction. Its contribution dominates the total cross section of $\pi^+ p$ ($T = 3/2$) process and is also important to the other isospin channels. The lowest energy hyperon resonances and their main decay modes are quite well known, so it is possible to use these resonances replacing $\Delta(1232)$. As for the coupling constants, they can be estimated from the resonance widths [3].

Another detail we have to take into account is the unitarization of the amplitudes. In an effective model like the one we are considering, the amplitudes we directly obtain are real, consequently violate the unitarity of the $S$ matrix. So, if we want something more than simple cross sections, some procedure is required to unitarize the amplitudes. As is often done in effective models [18], [20], [21], [23], and will be explained in detail in the next section, we will do this by reinterpreting the calculated amplitudes as elements of reaction matrix $K$.

Now we are ready to calculate all the phase shifts and then the total cross sections, angular distributions and polarizations. Because we are interested in low energies ($k \leq 0.4$ GeV), we will limit ourselves to the $S$ and $P$ waves, which are generally enough for our purpose.

### III. PION-LAMBDA INTERACTION

The $\pi \Lambda$ interaction is the simplest case. Since $\Lambda$ has isospin 0, the scattering amplitude $T_{\pi \Lambda}$ has the general form

$$T_{\pi \Lambda}^{ba} = \pi \delta \rho \rho [A(k, \theta) + \frac{(k + k')}{2} B(k, \theta) \delta_{ba}] \phi$$ \tag{5}$$

where $p_\mu$ and $p'_\mu$ are the initial and final 4-momenta of $\Lambda$ in the center of mass frame, $k_\mu$ and $k'_\mu$ are those of the pion, and $\theta$ the scattering angle. Indices $a$ and $b$ indicate the initial and final isospin states of the pion. We show in Fig. 1 the relevant diagrams, where we have omitted the crossed diagrams, although included in the calculations. We consider only the first resonance $\Sigma^*(1385)$, because we are interested in the low-energy ($k \leq 0.4$ GeV) behavior. The $\rho$ exchange term is absent in the $\pi \Lambda$ case, because due to the isospin it does not couple to $\Lambda$. To computing the first two of these diagrams, the Lagrangians [1] and [3] have been adapted to

$$\mathcal{L}_{\Lambda \pi \Sigma} = \frac{g_{\Lambda \pi \Sigma}}{2m_\Lambda} \lbrace \bar{\Sigma} \gamma_\mu \gamma_5 \Lambda \partial^\mu \phi + H.c. \rbrace$$ \tag{6}$$

$$\mathcal{L}_{\Lambda \pi \Sigma \cdot} = g_{\Lambda \pi \Sigma} \lbrace \bar{\Sigma} \gamma_\mu \gamma_5 \Lambda \partial^\mu \phi + \gamma_5 \partial^\mu \phi + H.c. \rbrace$$ \tag{7}$$

by replacing the nucleon by $\Lambda$ or $\Sigma$, and $\Delta$ by $\Sigma^*$ and performing appropriate sums over isotopic spin indices.

![Fig. 1: Diagrams for $\pi \Lambda$ Interaction](image)

The contributions of the diagram (1a) to the amplitudes are

$$A_{\Sigma} = \frac{g^2_{\Lambda \pi \Sigma}}{4m_\Lambda^3} (m_\Lambda + m_\Sigma) \left\{ \frac{s - m_\Sigma^2}{s - m_\Lambda^2} + \frac{u - m_\Sigma^2}{u - m_\Lambda^2} \right\}$$

$$B_{\Sigma} = \frac{g^2_{\Lambda \pi \Sigma}}{4m_\Lambda^3} \left\{ \frac{m_\Sigma^2 - s - 2m_\Lambda(m_\Lambda + m_\Sigma)}{s - m_\Sigma^2} + \frac{2m_\Lambda(m_\Lambda + m_\Sigma) + u - m_\Sigma^2}{u - m_\Lambda^2} \right\}$$ \tag{8}$$

The diagram (1b) gives
\[ A_{\Sigma'} = \frac{g_{\Sigma\Sigma'}^2}{3m_\Lambda} \left( \frac{\nu_r}{\nu^2 - \nu^2} \hat{A} - \frac{m_\Lambda^2 + m_\Lambda m_{\Sigma'}}{m_{\Sigma'}^2} \right) \times \left( 2m_{\Sigma'}^2 + m_{\Lambda} m_{\Sigma'} - m_{\Lambda}^2 + 2m_{\pi}^2 \right) + \frac{4m_{\Lambda}}{m_{\Sigma'}^2} \left( (m_{\Lambda} + m_{\Sigma'})Z + (2m_{\Sigma'} + m_{\Lambda})Z^2 \right) \text{k.k'} \right) ,
\]
\[ B_{\Sigma'} = \frac{g_{\Sigma\Sigma'}^2}{3m_\Lambda} \left( \frac{\nu}{\nu^2 - \nu^2} \hat{B} - \frac{8m_{\pi}^2 \nu Z^2}{m_{\Sigma'}^2} \right) , \tag{9} \]

where \( \nu \) and \( \nu_r \) are defined in the Appendix and
\[ \hat{A} = \frac{(m_{\Sigma'}^2 + m_\Lambda)^2 - m_\pi^2 [2m_{\Sigma'}^2 - 2m_\Lambda^2 - 2m_\Lambda m_{\Sigma'}^2.}{2m_{\Sigma'}^2} \]
\[ \hat{B} = \frac{1}{2m_{\Sigma'}^2} \left[ (m_{\Sigma'}^2 - m_\Lambda^2)^2 - 2m_\pi^2 (m_{\Sigma'}^2 + m_\Lambda^2 + m_\pi^2) \right] + \frac{3}{2} \frac{t}{t} . \tag{10} \]

As for the diagram (1c), we only parametrize the amplitudes as done in [16]
\[ A_\sigma = a + bt , \]
\[ B_\sigma = 0 , \tag{11} \]
where \( a = 1.05 m_{\pi}^{-1} \) and \( b = -0.80 m_{\pi}^{-3} \) are constants (we use the same values of [22] for \( \pi N \)). The scattering matrix will then have the form
\[ M_{ba} = \frac{T_{ba}}{8\sqrt{s}} = f_1 + \frac{(\bar{\sigma}, \vec{k}) (\bar{\sigma}, \vec{k'})}{kk'} f_2 \tag{12} \]
and we can make the partial wave decomposition with
\[ a_{l\pm} = \frac{1}{2} \int_{-1}^{1} \left[ P_l(x) f_1(x) + P_{l+1}(x) f_2(x) \right] . \tag{13} \]

The amplitudes \( a_{l\pm} \), calculated in a tree-level approximation, are real and, so, the corresponding \( S \) matrix is not unitary. In order to unitarize these amplitudes, we reinterpret them as elements of \( K \) matrix and write
\[ a_{l\pm}^U = \frac{a_{l\pm}}{1 - ik a_{l\pm}} . \tag{14} \]

The phase-shifts are then computed as
\[ \delta_{l\pm} = tg^{-1} (k a_{l\pm}) . \tag{15} \]

The parameters we use are \( m_\Lambda = 1.115 \text{ GeV}, m_{\Sigma'} = 1.192 \text{ GeV}, m_{\Sigma'} = 1.385 \text{ GeV}, m_{\pi} = 0.139 \text{ GeV} \) [22], \( g_{\Lambda \Sigma} = 11.7 \) [23] and \( Z = -0.5 \) [22]. The only parameter that is missing is \( g_{\Lambda \Sigma' \Sigma} \). As mentioned before, we estimate it from the resonance width. Namely, by comparing the \( \delta_{p3} \) phase-shift in the resonance region with the relativistic Breit-Wigner expression [24].

\[ \delta_{l\pm} = tg^{-1} \left( \frac{\Gamma_0 (\frac{k_0}{s})^{2l}}{2(m_r - \sqrt{s})} \right) , \tag{16} \]

where \( k_0 \) is the center-of-mass momentum at the peak of \( \Sigma^* (1385) \), that is 0.207 GeV. The value obtained in this way is \( g_{\Lambda \Sigma \Sigma'} = 9.38 \text{ GeV}^{-1} \), which we will use here.

In Fig. 2, we show the calculated phase-shifts as functions of the center-of-mass momentum \( k \). We also show there the \( k \) dependence of the total elastic cross section, the angular distribution and the \( \Lambda \) polarization as function of \( x = \cos \theta \), for \( k = 100, 200, 300 \) and 400 MeV.

![Fig. 2: \( \pi \Lambda \) Scattering](image)

As we can see, the \( \Sigma^* (1385) \) contribution dominates the total elastic cross section in the low energy region (quite similar to \( \pi^+ p \) scattering). As for the polarization, it begins positive at lower energies and then becomes negative above \( k \sim k_0 \).

### IV. PION-SIGMA INTERACTION

In the case of \( \pi \Sigma \) interaction, both \( \pi \) and \( \Sigma \) have isospin 1, so the compound system can have isospin 2,1 or 0. For
this reason, the scattering amplitude is somewhat more complex in this case and has the following general form

\[ T_{\alpha\gamma,\beta\delta} = \langle \pi\Sigma|T|\pi_0\Sigma\rangle \delta_{\alpha\beta}\delta_{\gamma\delta} \]

\[ = \pi(p')\left\{ [A + \frac{(k + k')}{2} A']\delta_{\alpha\beta}\delta_{\gamma\delta} + [B + \frac{(k + k')}{2} B']\delta_{\alpha\gamma}\delta_{\beta\delta} + [C + \frac{(k + k')}{2} C']\delta_{\alpha\delta}\delta_{\beta\gamma} \right\} u(p') \],

where \( \alpha, \beta, \gamma \) and \( \delta \) are isospin indices. Decomposing this amplitude into the \( i \)-th iso-spin states of the system (\( P_i \) are the projection operators), we have

\[ T_{\alpha\gamma,\beta\delta} = \pi(p')\left\{ [A_0 + \frac{(k + k')}{2} B_0]P_0 + [A_1 + \frac{(k + k')}{2} B_1]P_1 + [A_2 + \frac{(k + k')}{2} B_2]P_2 \right\} u(p') \]

Comparing (17) and (18) we obtain

\[ \begin{align*}
A_0 &= 3A + B + C \\
A_1 &= B - C \quad , \\
A_2 &= B + C
\end{align*} \]

(19)

These are the relations that determine all the amplitudes projected on iso-spin states.

The interaction Lagrangians are given by (1), (2) and

\[ \mathcal{L}_{\Sigma\Sigma} = \frac{g_{\Sigma\Sigma}}{2m_\Sigma}(\overline{\Sigma}\gamma\mu\gamma\nu\Sigma)\partial^\mu\bar{\phi} , \]

\[ \mathcal{L}_{\Sigma\rho} = \frac{g_0}{2}(\overline{\Sigma}\gamma\mu\Sigma)\partial^\mu\rho + \frac{g_0}{2}(\overline{\Sigma}(\mu\Sigma - \mu\Sigma)\overline{\Sigma})i\sigma_{\mu\nu}\bar{\Sigma} , \]

where the iso-spin combination matrix \( \bar{t} \) obeys

\[ \langle \beta|\bar{t}|\alpha \rangle = -i\epsilon_{\beta\gamma\delta}\epsilon_{\gamma\delta} \].

Figure 3 shows the diagrams we consider for the \( \pi\Sigma \) interactions. \( \Sigma^*(1385) \) also couples to \( \pi\Sigma \), but its decay branching ratio back to the \( \pi\Sigma \) channel is only 11%. So, we will neglect it.

The amplitudes corresponding to the diagram a), Fig. 3, are

\[ A_\Lambda = \frac{g_{\Lambda\Sigma\Sigma}}{4m_\Sigma}(m_\Sigma + m_\Lambda) \frac{s - m_\Sigma^2}{s - m_\Lambda^2} , \]

\[ B_\Lambda = 0 , \]

\[ C_\Lambda = \frac{g_{\Lambda\Sigma\Sigma}}{4m_\Sigma}(m_\Sigma + m_\Lambda) \frac{u - m_\Sigma^2}{u - m_\Lambda^2} , \]

\[ A'_\Lambda = \frac{g_{\Lambda\Sigma\Sigma}}{4m_\Sigma}(m_\Sigma + m_\Lambda) \frac{s - 2m_\Sigma(m_\Sigma + m_\Lambda)}{s - m_\Lambda^2} , \]

\[ B'_\Lambda = 0 , \]

\[ C'_\Lambda = \frac{g_{\Lambda\Sigma\Sigma}}{4m_\Sigma}2m_\Sigma(m_\Sigma + m_\Lambda) + u - m_\Sigma^2 \]

The contributions of the diagram b) with intermediate \( \Lambda^*(1405) \) are similar. We must only change the coupling constant and replace the mass \( m_\Lambda \) by \( m_\Lambda' \).

In the case of the intermediate \( \Sigma \), diagram d), we have

\[ A_\Sigma = \frac{g_{\Sigma\Sigma\Sigma}}{2m_\Sigma} , \]

\[ B_\Sigma = \frac{g_{\Sigma\Sigma\Sigma}}{m_\Sigma} , \]

\[ C_\Sigma = \frac{g_{\Sigma\Sigma\Sigma}}{2m_\Sigma} , \]

\[ A'_\Sigma = \frac{g_{\Sigma\Sigma\Sigma}}{4m_\Sigma^2} - \frac{g_{\Sigma\Sigma\Sigma}}{2m_\Sigma} \frac{1}{m_\Sigma} \]

\[ B'_\Sigma = \frac{g_{\Sigma\Sigma\Sigma}}{m_\Sigma} \frac{\nu}{\nu_0 - \nu} , \]

\[ C'_\Sigma = \frac{g_{\Sigma\Sigma\Sigma}}{2m_\Sigma^2} + \frac{g_{\Sigma\Sigma\Sigma}}{2m_\Sigma} \frac{1}{\nu_0 + \nu} . \]

The \( \rho \) exchange amplitude, diagram e), has the form

\[ T_\rho = \pi(p')\left\{ [A_0 + \frac{(k + k')}{2} B_0]\delta_{\alpha\beta}\delta_{\gamma\delta} - \delta_{\alpha\delta}\delta_{\beta\gamma} \right\} u(p') , \]

so

\[ \begin{align*}
A_0 &= 2A_\rho \\
A_1 &= A_\rho \quad , \\
A_2 &= -A_\rho \quad , \end{align*} \]

(26)

with

\[ A_\rho = -\frac{g_0}{m_\rho^2}(\mu_\rho - \mu_\Sigma)(\nu - t)^{1/2} \]

\[ B_\rho = \frac{g_0}{m_\rho^2}(1 + \mu_\rho - \mu_\Sigma)(\nu - t)^{1/2} . \]
Finally, the $\sigma$-term has been parametrized in the same way as for $\pi \Lambda$, by using eqs. (11), with the same parameters. In addition to the parameters used in the $\pi \Lambda$ case, we use here $m_{\Lambda^*} = 1.406$ GeV, $m_\rho = 769$ GeV, $\mu_{\Sigma^0} = 649$, $\mu_{\Sigma^-} = -0.16$ and $g_{\Sigma \pi \Lambda^*} = 6.7$ [27]. The coupling constant $g_{\Sigma \pi \Lambda^*}$ is not known, but we can proceed in the same way as we have done before, comparing the calculated amplitudes with the Breit-Wigner expression. The best fit is obtained with $g_{\Sigma \pi \Lambda^*} = 8.74$ GeV$^{-1}$.

We show in Fig. 4 the phase shifts calculated as explained above. It is also shown the energy dependence of the cross section $\sigma_i$ for each channel described below.

$$\langle \pi^- \Sigma^+ | T | \pi^+ \Sigma^- \rangle = \langle \pi^+ \Sigma^- | T | \pi^+ \Sigma^- \rangle = \frac{T_2}{2} - \frac{T_1}{2} + \frac{T_0}{3}$$

$$\langle \pi^+ \Sigma^0 | T | \pi^0 \Sigma^0 \rangle = \langle \pi^- \Sigma^- | T | \pi^0 \Sigma^- \rangle = \langle \pi^0 \Sigma^+ | T | \pi^+ \Sigma^0 \rangle = \langle \pi^0 \Sigma^- | T | \pi^- \Sigma^- \rangle = \langle \pi^0 \Sigma^0 | T | \pi^+ \Sigma^- \rangle = \frac{T_2}{2} - \frac{T_1}{2} .$$

$$\langle \pi^- \Sigma^- | T | \pi^+ \Sigma^- \rangle = \langle \pi^+ \Sigma^0 | T | \pi^0 \Sigma^0 \rangle = \langle \pi^- \Sigma^- | T | \pi^0 \Sigma^- \rangle = \langle \pi^0 \Sigma^+ | T | \pi^+ \Sigma^0 \rangle = \langle \pi^0 \Sigma^- | T | \pi^- \Sigma^- \rangle = \langle \pi^0 \Sigma^0 | T | \pi^+ \Sigma^- \rangle = \frac{T_2}{2} - \frac{T_1}{2} .$$

Fig. 4: Phase-shifts and the energy dependence of $\sigma_i$ for $\pi \Sigma$ interactions

Using the isospin formalism we calculate the elastic, as well as the charge exchange, amplitudes as

$$\langle \pi^+ \Sigma^+ | T | \pi^+ \Sigma^+ \rangle = \langle \pi^- \Sigma^- | T | \pi^- \Sigma^- \rangle = T_2$$

$$\langle \pi^+ \Sigma^0 | T | \pi^0 \Sigma^0 \rangle = \langle \pi^- \Sigma^- | T | \pi^0 \Sigma^- \rangle = \langle \pi^0 \Sigma^+ | T | \pi^+ \Sigma^0 \rangle = \langle \pi^0 \Sigma^- | T | \pi^- \Sigma^- \rangle = \frac{T_2}{2} + \frac{T_1}{2}$$

$$\langle \pi^0 \Sigma^- | T | \pi^0 \Sigma^- \rangle = \frac{2T_2}{3} + \frac{T_0}{3}$$

$$\langle \pi^- \Sigma^- | T | \pi^+ \Sigma^- \rangle = \langle \pi^+ \Sigma^+ | T | \pi^- \Sigma^+ \rangle = \frac{T_2}{6} + \frac{T_1}{2} + \frac{T_0}{3}$$

Fig. 5: Angular distributions of $\Sigma^+$
With these amplitudes, we can calculate $\sigma$, $d\sigma/d\Omega$ and $P$ as functions of $k$ and $x = \cos \theta$ for each channel. The results for $\Sigma^+$ in the final state are shown in Figs. 4–6.

Before passing to the next section, it is worth-while making the following remarks. Even in the tree-level calculation and in the low-energy ($k \lesssim 0.4$ GeV) region that we are considering here, there could occur the exchange reactions $\pi \Lambda \rightarrow \pi \Sigma$. The possible diagrams for these are similar to Fig. 1 b) and Figs. 3 b) and c), with one of $\Lambda (\Sigma)$ replaced by $\Sigma (\Lambda)$. However, the contributions of these reactions are small compared with the elastic ones we examined in this paper. First, as mentioned before and could be seen in Figs. 2 and 4, the direct-resonances dominate over all the other processes, which appear as corrections to the former. They don’t change much the cross sections, however are necessary to produce polarization. Now, $\pi \Sigma \rightarrow \pi \Lambda$, which is given by the $\Sigma^*$ term together with $\rho$ exchange one, is much smaller than $\pi \Lambda \rightarrow \pi \Lambda$, because the branching ratio of $\Sigma^*$ decay is $(\Sigma^* \rightarrow \pi \Sigma)/(\Sigma^* \rightarrow \pi \Lambda) \sim 0.16$. As for $\pi \Lambda \rightarrow \pi \Sigma$ compared with $\pi \Sigma \rightarrow \pi \Sigma$, as mentioned above first we have $\sigma(\pi \Lambda \rightarrow \pi \Sigma)/\sigma(\pi \Lambda \rightarrow \pi \Lambda) \sim 0.16$ for each possible channel. Now, from Figs. 2 and 4, each $\pi \Lambda \rightarrow \pi \Lambda$ channel, compared with the sum of the three prominent $\pi \Sigma \rightarrow \pi \Sigma$ channels, gives $\sigma(\pi \Lambda \rightarrow \pi \Lambda)/\sum \sigma(\pi \Sigma \rightarrow \pi \Sigma) \sim 0.60$ on the average in the resonance region. So, we estimate that the overall $\pi \Lambda \rightarrow \pi \Sigma$ contribution is less than 20% of $\pi \Sigma \rightarrow \pi \Sigma$ examined here.

V. $\pi \Xi$ INTERACTION

This case is very similar to the $\pi N$ scattering, because $\Xi$ has isospin 1/2 (as the nucleon) and the main difference is that the resonance of interest $\Xi^*(1533)$ has isospin $I=1/2$ (instead of $I=3/2$ as $\Delta(1232)$). Then, the scattering amplitude $T_{ba}^{\pi \Xi}$ has the general form

$$
T_{ba}^{\pi \Xi} = \pi(\bar{\mu}i\tau)\{[A^+ + (k+k')B^+]\delta_{ba} + [A^- + (k+k')B^-i\epsilon_{bac}^{-c}]u(\bar{b})\} .
$$

(29)

The contributing diagrams are in Fig. 7 and the Lagrangians are almost the same as in the case of $\pi N$ scattering, eqs. (14), where we must replace the $N$ field by $\Xi$ field, and $\Delta(1232)$ by $\Xi^*(1533)$. The latter implies a substitution of the isospin matrix $\vec{M}$ by $\vec{\tau}$. Consequently, $A^\pm$ and $B^\pm$ have different structures as compared with $A^\pm_\Lambda$ and $B^\pm_\Lambda$ of $\pi N$ case, whereas all the other $A^\pm$ and $B^\pm$ remain the same, with appropriate parameter changes.

Fig. 6: Polarization of $\Sigma^+$

We can see in Fig. 4 that, although the first resonance is important in $\pi \Sigma$ interactions, it is not as much as in the $\pi^+ p$ or $\pi^0 N$ scatterings. The peak in the $\Lambda^*(1405)$-mass region is not so high (less than 30 mb) and it appears in the $I = 0$ state ($\pi^- \Sigma^+$). Remark that the other reactions ($I = 1$ and especially $I = 2$) have comparable total cross sections.

Fig. 7: Diagrams to $\pi \Xi$ Interaction
So, by computing the Feynman diagram a) in Fig. 7, we obtain

\[ A^+_{\Xi} = \frac{g^2_{\Xi\pi\Xi}}{m_\Xi} , \]

\[ A^-_{\Xi} = 0 , \]

\[ B^+_{\Xi} = \frac{g^2_{\Xi\pi\Xi}}{m_\Xi} \frac{\nu}{\nu^2_0 - \nu^2} , \]

\[ B^-_{\Xi} = -\frac{g^2_{\Xi\pi\Xi}}{2m_\Xi} - \frac{g^2_{\Xi\pi\Xi}}{m_\Xi} \frac{\nu_0}{\nu^2_0 - \nu^2} . \]  

The \( \rho \) exchange, diagram d), gives

\[ A^+_{\rho} = B^+_{\rho} = 0 , \]

\[ A^-_{\rho} = -\frac{g^2_{\rho\pi\rho}}{m_\rho^2} (\mu_\rho - \mu_{\Xi}) \frac{1 - t/4m_\rho^2}{1 - t/m_\rho^2} , \]

\[ B^-_{\rho} = \frac{g^2_{\rho\pi\rho}}{m_\rho^2} (1 + \mu_\rho - \mu_{\Xi}) \frac{1 - t/4m_\rho^2}{1 - t/m_\rho^2} . \]

The contributions from diagram b) with intermediate \( \Xi^*(1533) \) are

\[ A^+_{\Xi^*} = \frac{g^2_{\Xi^*\pi\Xi}}{3m_{\Xi^*}} \left( \frac{\nu_r}{\nu^2_r - \nu^2} \hat{A} - \frac{m^2 + m_\Xi m_{\Xi^*}}{m_{\Xi^*}^2} \right. \]

\[ \times \left( 2m^2_{\Xi^*} + m_\Xi m_{\Xi^*} - m^2_{\pi} + 2m^2_{\rho} \right) \]

\[ + \frac{4m_{\Xi^*}^2}{m_{\Xi^*}^2} \left( (m_\Xi + m_{\Xi^*}) Z + (2m_{\Xi^*} + m_\Xi) Z^2 \right) \bigl[ k, k' \bigr] \] \]

\[ A^-_{\Xi^*} = \frac{g^2_{\Xi^*\pi\Xi}}{3m_{\Xi^*}} \left( \frac{\nu_r}{\nu^2_r - \nu^2} \hat{B} + \frac{8m^2_{\Xi^*} \nu^2}{m_{\Xi^*}^2} \right. \]

\[ \times \left( (m_\Xi + m_{\Xi^*}) Z + (2m_{\Xi^*} + m_\Xi) Z^2 \right) \bigl[ k, k' \bigr] \] \]

\[ B^+_{\Xi^*} = \frac{g^2_{\Xi^*\pi\Xi}}{3m_{\Xi^*}} \left( \frac{\nu_r}{\nu^2_r - \nu^2} \hat{B} - m_\Xi \frac{(m_\Xi + m_{\Xi^*})^2}{m_{\Xi^*}^2} - \frac{4m_{\Xi^*}Z^2}{m_{\Xi^*}^2} \bigl[ k, k' \bigr] \right. \]

\[ - \frac{4m_{\Xi^*}^2}{m_{\Xi^*}^2} \left( (2m^2_{\Xi^*} + 2m_\Xi m_{\Xi^*} - 2m_{\rho}^2) Z \right. \]

\[ \left. + (2m^2_{\Xi^*} + 4m_\Xi m_{\Xi^*}) Z^2 \right) \bigl[ k, k' \bigr] \] \]

\[ B^-_{\Xi^*} = \frac{g^2_{\Xi^*\pi\Xi}}{3m_{\Xi^*}} \left( \frac{\nu_r}{\nu^2_r - \nu^2} \hat{B} - m_\Xi \frac{(m_\Xi + m_{\Xi^*})^2}{m_{\Xi^*}^2} - \frac{4m_{\Xi^*}Z^2}{m_{\Xi^*}^2} \bigl[ k, k' \bigr] \right. \]

\[ - \frac{4m_{\Xi^*}^2}{m_{\Xi^*}^2} \left( (2m^2_{\Xi^*} + 2m_\Xi m_{\Xi^*} - 2m_{\rho}^2) Z \right. \]

\[ \left. + (2m^2_{\Xi^*} + 4m_\Xi m_{\Xi^*}) Z^2 \right) \bigl[ k, k' \bigr] \] \]  

where

\[ \hat{A} = \frac{(m_\Xi + m_{\Xi^*})^2 - m_{\Xi^*}^2}{2m_{\Xi^*}^2} \left( 2m^3_{\Xi^*} - 2m^2_{\Xi} - 2m_{\Xi^*}m_{\Xi^*} \right) \]

\[ - \frac{2m^2_{\Xi^*} m_\Xi + m_{\Xi^*}^2 (2m_{\Xi^*} - m_\Xi) + \frac{3}{2} (m_\Xi + m_{\Xi^*}) t}{m_{\Xi^*}^2} , \]

\[ \hat{B} = \frac{1}{2m_{\Xi^*}^2} \left( (m_{\Xi^*}^2 - m_{\Xi^*}^2)^2 - 2m^2_{\Xi^*} (m_{\Xi^*}^2 + m_{\Xi^*})^2 + m_{\Xi^*}^4 \right) + \frac{3}{2} t . \]

The parameters used are \( m_{\Xi^*} = 1.318 \text{ GeV}, m_{\Xi^*} = 1.533 \text{ GeV}, \mu_{\Xi^*} = -1.25, \mu_{\Xi^*} = 0.349 \) and \( g_{\Xi^*\pi\Xi} = 4. \) As

in the previous cases, we determined the \( \Xi\pi\Xi^* \) coupling constant by using the Breit-Wigner formula and got the value \( g_{\Xi^*\pi\Xi} = 4.54 \text{ GeV}^{-1} \). We display in Fig. 8 the calculated phase shifts to the isospin 1/2 and 3/2 states.

![Fig. 8: Phase shifts for \( \pi\Xi \) interaction](image)

We can now obtain the matrix elements for each elastics and charge-exchange channel as

\[
\langle \pi^+\Xi^0 | T | \pi^+\Xi^0 \rangle = \langle \pi^-\Xi^- | T | \pi^-\Xi^- \rangle = T_{\frac{1}{2}}^\uparrow ,
\]

\[
\langle \pi^+\Xi^- | T | \pi^+\Xi^- \rangle = \langle \pi^-\Xi^0 | T | \pi^-\Xi^0 \rangle = \frac{1}{3} T_{\frac{3}{2}}^\uparrow + \frac{2}{3} T_{\frac{1}{2}}^\uparrow ,
\]

\[
\langle \pi^0\Xi^- | T | \pi^0\Xi^- \rangle = \langle \pi^0\Xi^0 | T | \pi^0\Xi^0 \rangle = \frac{2}{3} T_{\frac{3}{2}}^\uparrow + \frac{1}{3} T_{\frac{1}{2}}^\uparrow ,
\]

\[
\langle \pi^-\Xi^0 | T | \pi^-\Xi^- \rangle = \langle \pi^-\Xi^+ | T | \pi^-\Xi^0 \rangle = \frac{\sqrt{3}}{3} T_{\frac{3}{2}}^\uparrow - \frac{\sqrt{3}}{3} T_{\frac{1}{2}}^\uparrow .
\]

(34)

![Fig. 9: Total cross sections for \( \pi\Xi \) interaction](image)
We show, in Fig. 9, the integrated cross sections, with \( \Xi^- \) in the final state, obtained with these matrix elements. We can see that in this case the \( \Xi(1533) \) resonance contribution is very important and it dominates three of the reactions. Figure 10 presents the angular distributions and polarizations for the same reactions.

**VI. DISCUSSION OF THE RESULTS**

In the preceding sections, by making a close analogy with the well established \( \pi N \) case, we have calculated the \( S- \) and \( P- \) wave phase shifts for \( \pi \Lambda, \pi \Sigma \) and \( \pi \Xi \) interactions. Then obtained both the integrated and differential cross sections and polarizations for all the elastic and charge-exchange processes. Let us now discuss these results in connection with the two applications we mentioned in the introduction.

The first application refers to the study of the CP violation. One of the ways to verify this violation is to observe the hyperon weak decays, \( \Lambda \to \pi N, \Sigma \to \pi N, \Xi \to \pi \Lambda \) and \( \Omega \to \pi \Xi \). In such a study, we need an independent estimate of the strong-interaction phase shifts in the final state.

For \( \Lambda- \) and \( \Sigma- \) decays, a large amount of data are available on the strong interaction phase shifts, since \( \pi N \) scatterings are very well studied. In the \( \Xi \) decay, there are some estimates of the \( S- \) and \( P-1 \) wave phase shifts for \( \pi \Lambda \) system. However, the reported results are conflicting with each other. Whereas the authors of [3] give \( \delta_S = -18.7^\circ \) and \( \delta_{P1} = -2.7^\circ \), in [5], they tell that \( \delta_S = 1.2^\circ \) and \( \delta_{P1} = -1.7^\circ \) and, as for the Ref. [3], \( \delta_S \) is between \(-1.3^\circ \) and \(0.1^\circ\) and \( \delta_{P1} \) between \(-4.0^\circ\) and \(-3.0^\circ\). In our calculation, with the \( \sigma \) term included, we obtained \( \delta_{P1} = -0.36^\circ \) and \( \delta_S = -4.69^\circ \) at the \( \Lambda \)-mass value, that gives \( \delta_S - \delta_{P1} \sim -4.3^\circ \), that is still small. One should remark that to really fit the phase shifts in \( \pi N \) scattering, especially \( \delta_S \), it is necessary to include other contributions as the diffractive [10] or the contact [21] terms with correct parameters. So it is possible that some correction is needed in the results we have obtained here.

In this paper, we have also calculated the \( \pi \Xi \) phase shifts. So, it is possible to get some information about the CP violation in the \( \Omega \to \pi \Xi \) decay, too. \( \Omega \) has \( J^P = \frac{3^+}{2} \), so the phase shifts we need are \( \delta_{P3}^\Omega \) and \( \delta_{D3}^\Omega \). Calculating the asymmetry parameter \( A \) in the same way as in [5], the approximate expression reads

\[
A = -\tan(\delta_{P3} + \delta_{D3}) \tan(\frac{\phi_{P3} - \phi_{D3}}{2}) \\
\sim -\tan(\delta_{P3}) \tan(\frac{\phi_{P3} - \phi_{D3}}{2}). \tag{35}
\]

At the \( \Omega \) mass value, \( \delta_{D3}^\Omega = 0.21^\circ \) (computed with the
same diagrams used in sec. 5) and $\delta_{P3} = 173.04^\circ = 180^\circ - 6.96^\circ$. So the strong interaction effect in the asymmetry parameter will appear as $\tan(-7.17^\circ)$ that is a value close to that obtained in the $\Xi$ decay. So we do not expect that, in the study of CP violation in hyperon weak decays, $\Omega \to \pi \Xi$ is much useful.

The other application we mentioned in the introduction, and which was the main motivation of this work, is the inclusive (anti-)hyperon polarization in high-energy collisions. As explained there, the anti-hyperon polarization cannot be understood in terms of the usual models $\left[1,2,3\right]$, because all of them are based on the leading-particle effect and an anti-hyperon cannot be a leading particle. In $\left[4\right]$ it has been proposed that anti-hyperons are polarized when interacting with the surrounding particles, which are predominantly pions, that make the environment where they are produced. So the anti-hyperon polarization would appear as an average effect of the low energy $\pi Y$ interaction. It is clear that, generally speaking, such an average procedure washes out any existent asymmetry, so that no polarization would appear as a consequence. This is true if we look at the central region of the collision. However, the polarization data are obtained in very forward directions where the asymmetry could be preserved. Such calculations will be reported elsewhere $\left[25\right]$, but just observing the results of the preceding sections we can draw some conclusions. The $\Lambda$ polarization, as seen in Fig. 2, is positive below 100 Mev and then changes the sign, so we expect that, on averaging, the most part will be canceled out, implying that the polarization of $\overline{\Lambda} \sim 0$. As seen in Figs. 9 and 10, the $\Sigma^-$ polarization is negative and very large in the channels where the cross section is large, whereas the $\Sigma^-$ polarization is positive in most of the cases, Figs. 6. As we can see, the hyperon polarization is different in each case, and seems to be consistent with the experimental data for the anti-hyperons $\left[25\right]$. Remark that the polarization sign changes under charge conjugation.

Acknowledgments

We would like to thank M.R. Robilotta for the discussions about the hadron interactions and comments on the manuscript. This work was partially supported by CNPq and FAPESP (contract nos. 98/02249-4 and 00/04422-7).

APPENDIX A: BASIC FORMALISM

In this paper $p$ and $p'$ are the initial and final hyperon 4-momenta, $k$ and $k'$ are the initial and final pion 4-momenta, so the Mandelstam variables are

$$s = (p + k)^2 = (p' + k')^2 \quad (A1)$$
\[ t = (p - p')^2 = (k - k')^2 \]  
\[ u = (p' - k)^2 = (p - k')^2 . \]  
\[(A2)\]

With these variables, we can define
\[ \nu = \frac{s - u}{4m} \quad \nu_0 = \frac{2m^2 - t}{4m} \quad \nu_r = \frac{m_r^2 - m^2 - |kk'|}{2m} , \]  
\[(A3)\]

where \( m, m_r, \) and \( m_\pi \) are, respectively, the hyperon mass, the resonance mass and the pion mass. The scattering amplitude for an isospin \( I \) state is
\[ T_I = \pi(\vec{p}')(\{A'_I + \frac{[k + k']}{2}B_I\})u(\vec{p}) , \]  
\[(A4)\]

where \( A_I \) and \( B_I \) are calculated using the Feynman diagrams. So the scattering matrix is
\[ M_{ba}^I = \frac{T_{ba}^I}{8\pi \sqrt{s}} = f_I(\theta) + \vec{\sigma}.\vec{n}g_I(\theta) = f'_I + \frac{(\vec{\sigma}.\vec{k})(\vec{\sigma}.\vec{k}')}{kk'}f_2^I , \]  
\[(A5)\]

with
\[ f'_I(\theta) = \frac{(E + m)}{8\pi \sqrt{s}}[A_I + (\sqrt{s} - m)B_I] , \]  
\[(A6)\]

\[ f_2^I(\theta) = \frac{(E - m)}{8\pi \sqrt{s}}[-A_I + (\sqrt{s} + m)B_I] , \]  
\[(A7)\]

where \( E \) is the hyperon energy. The partial-wave decomposition is done with
\[ a_{l\pm} = \frac{1}{2} \int_{-1}^{1} [P_l(x)f_{l}(x) + P_{l\pm}(x)f_2(x)] dx . \]  
\[(A8)\]

In our calculation (tree level) \( a_{l\pm} \) is real. With the unitarization, as explained in Section III, we obtain
\[ a_{l\pm}^U = \frac{1}{2ik}\left[e^{2i\delta_{l\pm}} - 1\right] = \frac{e^{i\delta_{l\pm}}}{k} \text{sen}(\delta_{l\pm}) \rightarrow a_{l\pm} . \]  
\[(A9)\]

These complex amplitudes are used to calculate
\[ f(\theta) = \sum_{i=0}^{\infty} (l + 1)a_{l+} + ia_{l-} P_l(x) , \]  
\[(A10)\]

\[ g(\theta) = i \sum_{l=1}^{\infty} [a_{l+} - a_{l-}] P^{(1)}_l(x) . \]  
\[(A11)\]

We have, then, in the center-of-mass frame,
\[ \frac{d\sigma}{d\Omega} = |f|^2 + |g|^2 , \]  
\[(A12)\]

\[ \vec{p} = -2 \frac{\text{Im}(f^*g)}{|f|^2 + |g|^2} \hat{n} , \]  
\[(A13)\]

\[ \sigma_l = 4\pi \sum_{l} [(l + 1)|a_{l+}|^2 + l|a_{l-}|^2] . \]  
\[(A14)\]
