University students’ awareness of causes and risk factors of miscarriage: a cross-sectional study

Indra San Lazaro Campillo, Sarah Meaney, Jacqueline Sheehan, Rachel Rice and Keelin O’Donoghue

Abstract

Background: Spontaneous miscarriage is the most common complication of pregnancy, occurring in up to 20% of pregnancies. Despite the prevalence of miscarriage, little is known regarding people’s awareness and understanding of causes of pregnancy loss. The aim of this study was to explore university students’ understanding of rates, causes and risk factors of miscarriage.

Methods: A cross-sectional study including university students. An online questionnaire was circulated to all students at the University College Cork using their university email accounts in April and May 2016. Main outcomes included identification of prevalence, weeks of gestation at which miscarriage occurs and causative risk factors for miscarriage.

Results: A sample of 746 students were included in the analysis. Only 20% (n = 149) of students correctly identified the prevalence of miscarriage, and almost 30% (n = 207) incorrectly believed that miscarriage occurs in less than 10% of pregnancies. Female were more likely to correctly identify the rate of miscarriage than men (21.8% versus 14.5%). However, men tended to underestimate the rate and females overestimate it. Students who did not know someone who had a miscarriage underestimated the rate of miscarriage, and those who were aware of some celebrities who had a miscarriage overestimated the rate. Almost 43% (n = 316) of students correctly identified fetal chromosomal abnormalities as the main cause of miscarriage. Females, older students, those from Medical and Health disciplines and those who were aware of a celebrity who had a miscarriage were more likely to identify chromosomal abnormalities as a main cause. However, more than 90% of the students believed that having a fall, consuming drugs or the medical condition of the mother was a causative risk factor for miscarriage. Finally, stress was identified as a risk factor more frequently than advanced maternal age or smoking.

Conclusion: Although almost half of the participants identified chromosomal abnormalities as the main cause of miscarriage, there is still a lack of understanding about the prevalence and most important risk factors among university students. University represents an ideal opportunity for health promotion strategies to increase awareness of potential adverse outcomes in pregnancy.

Background
Miscarriage is one of the most common complications in pregnancy [1]. It is estimated that one out of four clinically recognised pregnancies will end in miscarriage during the first-trimester, and approximately 1% of pregnant women will experience a second-trimester miscarriage [2]. Despite the prevalence of miscarriage, 50% are attributed to chromosomal abnormalities [3], and a considerable percentage are classified as unexplained [4]. Therefore, identifying risk factors and effective interventions to prevent miscarriage has become a priority in the medical and scientific community [5]. Well-known risk factors include advanced maternal and paternal age, heavy smoking, alcohol consumption, infertility and previous miscarriage [6–10].

Preconception health care aims to identify and increase awareness to reduce risk factors before pregnancy that might affect the future maternal, child and family health [11–13]. An effort has been made to develop effective intervention plans and to include preconception risk factors in prenatal prevention programs internationally [14–18]. One of the main recommendations is to promote effective preconception health care interventions to develop curricula of preconception risk factors at undergraduate and postgraduate level [15]. Insight into students’ awareness of miscarriage might help to assess the effectiveness of preconception care education at a university level, but also to highlight the gaps of knowledge among this targeted population. Therefore, a cross-sectional study was conducted to explore university students’ understanding of prevalence, causes and risk factors of miscarriage.

Methods
Study design and data source
A cross-sectional study was carried at University College Cork (UCC). Cork is one of the three cities in the Republic of Ireland with the highest full-time enrolments in the academic year 2016/2017 [19]. UCC currently has 20,000 full-time students of whom 14,000 are undergraduate [19]. It has over 3000 international students from 100 countries around the world. There are over 120 degree and professional programmes in Medicine, Dentistry, Pharmacy, Nursing and the Clinical Therapies, along with the Humanities, Business, Law, Architecture, Science, Food and Nutritional Sciences, available at UCC. Students were asked to select their area of study at UCC from a list of six options. For the purpose of this study, this list was grouped into four categories in accordance with the organisation of the Colleges within the University (i.e. The College of Medicine and Health, The College of Arts and Social Science, The College of Engineering & Food Science and The College of Business and Commerce & Law) [20]. For example, the College of Medicine and Health includes the Schools of Medicine, Dental School, Clinical Therapies, Nursing and & Midwifery, Pharmacy and Public Health.

An online questionnaire was circulated to all students at UCC using their university email accounts, in April and May 2016. The questionnaire was compiled using SurveyMonkey®, which is a user-friendly site to develop and administer online surveys. The questionnaire was anonymous and voluntary. An informed consent form explaining the objectives of the survey had to be completed before accessing the questionnaire. The main questionnaire consisted of twenty-six questions utilised to assess students’ understanding of the topic of miscarriage. Topics included general demographic and educational characteristics (i.e. sex, age, marital status, discipline and level of study), general knowledge and risk factors for miscarriage (i.e. agree, disagree and unsure of both well-known and spurious risk factors), identification of previous experience of miscarriage among themselves or their partners, and awareness of family member, friends or a celebrity who had a miscarriage. Students were asked to select the most common causes of miscarriage from a list of six options including lifestyle of mother (i.e. smoking and alcohol), medical condition or medical problem with the mother; genetic problem with the baby; psychological problems during pregnancy (i.e. stress, depression) and incident during pregnancy (i.e. fall, injury, accident). In addition, students were asked to provide rates of miscarriage in Ireland (i.e. “In your opinion, what percentage of pregnancies in Ireland ends in a miscarriage? Please insert a number anywhere from 0 to 100 %”) and weeks of gestation at which miscarriage occurs ("when can a miscarriage occur? Between week ‘x’ to week ‘x’ of a pregnancy").

Definitions of miscarriage vary significantly between countries and jurisdictions [21]. For the purposes of this study, miscarriage is defined as the spontaneous demise of a pregnancy from the time of conception up to 24 completed weeks of gestation [22–24]. This study also reported the number of students who were only aware of first trimester miscarriage, which is defined as the loss of a pregnancy up to 12 weeks of gestation [22–24]. It is estimated that approximately one fifth of clinical pregnancies will end in a miscarriage in Ireland [24]. Therefore, a rate of 20% of miscarriage was selected as the cut-off rate in this study.

Statistical analysis
Descriptive analysis was carried out using mean and standard deviation (SD) for continuous variables and percentages for categorical variables. Age was categorised using tertiles (i.e. 33.3% of the students were 21 years old or younger and 66.7% were 23 years old or younger). Three categories were created to calculate the
Results

Overall, 872 students responded to the online survey. Of those, 126 were excluded from the analysis because they did not complete more than half of the survey or they had highly extreme answers in demographic characteristics such as age. Therefore, a total sample of 746 university students were included in our analysis. The mean age was 24.3 years (SD = 6.58), and most of students were between 21 and 22 years old (n = 284; 38.1%) or were 23 years old or older (n = 289; n = 38.7%) ranging between 18 and 60 years old. More than half of the respondents were females (n = 577; 77.3%), and approximately 80% were single (n = 617). The discipline with the lower response rate was Business and Commerce and Law (n = 104; 13.9%) and with the highest response rate was Medicine and Health (n = 280; 31.9%).

Male students were more likely to report that they did not know anyone who had a miscarriage compared to female students (23.9% versus 9.6%; p < 0.001). Students aged 23 years old or older were more likely to report they knew someone who had a miscarriage; however, students of 20 years of age or younger were more likely to report they were aware of a celebrity who had had a miscarriage (p < 0.05). Single students were also more likely not to know anyone who had a miscarriage compared to those who had a partner, were married, were cohabiting or divorced (14.1% versus 5.8%; p < 0.05). Females were more likely to be aware of a celebrity who had a miscarriage than male students (16.9% versus 7.0%, Table 1). Students from Engineering and Food Science (n = 34; 18.3%) or Business and Commerce and Law (n = 14; 14.9%) disciplines were more likely to report that they did not know anyone with a miscarriage. Medicine and Health (n = 159; 74%), and Arts and Social Science (n = 130; 72.6%) were more likely to know someone who had a miscarriage (Table 1).

Only 20% (n = 149) of students identified a mean rate of 20% for miscarriage. The remaining students underestimated or overestimated the rate of miscarriage (Table 2). Female students, older students and those who knew someone who had a miscarriage were more likely to identify the 20% rate of miscarriage. Students from Arts and Social Science (n = 45; 22.5%) and Medicine and Health (n = 52, 21.9) were more likely to estimate the correct rate of miscarriage (Table 2). A total of 96 (12.9%) students correctly responded that miscarriage happens up to 12 weeks of gestation (early miscarriage) or up to 24 weeks of gestation (late miscarriage). Overall, only 54 (6.2%) students were aware that miscarriage can happen from conception until 24 weeks of gestation. A quarter of all students (n = 179; 24%) thought miscarriage could happen at any stage of pregnancy.

The most common cause of miscarriage identified by the university students was chromosomal abnormalities in the baby, (n = 316; 42.4%), followed by medical conditions (n = 177; 23.7%) and lifestyles (n = 109; 14.6%). Chromosomal abnormalities of the baby were identified as the most common cause of miscarriage in a higher percentage of female students, older students (i.e. 23 years old or older), students who reported being married, divorced or cohabiting, students from Medicine and Health and for those students who knew a celebrity who had a miscarriage. Male students, younger and single students, students from Engineering and Food Science and Business and Commerce and Law, and students who reported that they did not know anyone who...
### Table 1 University students’ characteristics by type of relationship with someone who had a miscarriage

|                  | Do not know anyone, n (%) | Myself, partner, family or friend, n (%) | Celebrities, n (%) | p-value |

*Missing data (n = 72)
had a miscarriage were more likely to report lifestyles and the medical condition of the mother as the most common cause of miscarriage (Table 3).

Students who correctly estimated the rate of miscarriage were more likely to select chromosomal abnormalities as the main cause of miscarriage (n = 72; 48.3% for correct rate of miscarriage, n = 136; 45.9% for overestimated rate and n = 107; 36.3% for underestimated rate; Table 3). Conversely, students who correctly identified the rate of miscarriage were less likely to select psychological problems as the main cause of miscarriage. Students who overestimated the rate of miscarriage were less likely to identify medical conditions of the mother as a cause of miscarriage, whereas those who underestimated were more likely to select it. Approximately 15% (underestimated rate n = 42; correct rate n = 22 and overestimated rate n = 44) of students selected lifestyle behaviour as the main cause of miscarriage independently of the selected rate of miscarriage (Table 3).

The most reported risk factors for miscarriage were accident or fall, drugs, medical condition of the mother, alcohol, stress, age smoking and being underweight. Most students disagreed that sexual intercourse, hair dye, vitamin C and exercise were risk factors for miscarriage (Fig. 1).

Overall, the majority of college students correctly selected age (n = 566; 88%) and medical conditions of the mother (n = 682; 98%) as contributory risk factors for miscarriage. No statistically significant differences between agree or disagree responses for age or for medical conditions of mother were found between groups (Additional file 1: Table S1). However, students from Arts and Social Science were more likely to be unsure about age as a risk factor (aOR 2.78; 95% CI 1.52–5.09). Students of 21 years of age or older were more likely to identify chromosomal abnormalities as a causative factor for miscarriage than those aged 20 years old or younger (students aged 21–22: aOR 0.27; 95% CI 0.12–0.61 and students

| Underestimate rate        | 295   | 42 (14.2)        | 89 (30.2)                        | 107 (36.3)                      | 19 (6.4)                                     | 34 (11.5)                      | 4 (1.4)     | 0.022   |
| Correct rate              | 149   | 22 (14.8)        | 30 (20.1)                        | 72 (48.3)                       | 3 (20)                                       | 18 (12.1)                      | 4 (2.7)     |         |
| Over-estimate rate        | 296   | 44 (14.9)        | 54 (18.2)                        | 136 (45.9)                      | 21 (7.1)                                     | 33 (11.1)                      | 8 (2.7)     |         |
aged 23 years old or older: aOR 0.48; 95% CI 0.24–0.96; Additional file 1: Table S1). Students from Arts and Social Science or Business and Commerce and Law more frequently did not identify chromosomal abnormalities as a potential causative factor compared to college students from Medical and Health (aOR 2.40; 95% CI 1.01–5.73 and aOR 3.0; 95% CI 1.16–7.73 respectively; Additional file 1: Table S1).

Male students were more likely to agree that smoking was a risk factor for miscarriage compared to female students (aOR 0.47; 95% CI 0.24–0.94). Older students (i.e. 23 years old or older) disagreed more frequently that smoking was a risk factor for miscarriage compared to students who were 20 years old or younger (aOR 2.09; 95% CI 1.08–4.07). Compared to students from Medicine and Health, the remaining disciplines disagreed more frequently that smoking was a risk factor. For alcohol, older students and those from Business and Commerce and Law were more likely to disagree that it was a risk factor for miscarriage (Additional file 1: Table S1).

Students from Arts and Social Science were more likely to identify flu vaccination as a risk factor for miscarriage (n = 25; 26.9%; Additional file 1: Table S2). Students from Engineering and Food Science and Business and Commerce and Law were more likely to identify verbal arguments as a risk factor for miscarriage (aOR 0.56; 95% CI 0.31–0.99 and aOR 0.42; 95% CI 0.21–0.82). Students between 21 and 22 years old were more likely to be unsure that vitamin C was a risk factor for miscarriage (aOR 2.85; 95% CI 1.21–6.72; Additional file 1: Table S2). Only students who were 23 years old or older were more likely to identify vitamin C as a spurious risk factor compared to students who were 20 years old or younger (aOR 2.34; 95% CI 1.03–5.34; Additional file 1: Table S2).

Among the remaining potential causative risk factors for miscarriage, male students were less likely to identify working night shifts and previous termination of pregnancy (TOP) as risk factors (aOR 0.45; 95% CI 0.25–0.80and aOR 0.44; 95% CI 0.26–0.72). Older students
(i.e. 23 years old or older) were less likely to identify caffeine as a risk factor (aOR 2.61; 95%CI 1.45–4.70). Compared to students from the college of Medicine and Health, those from Business and Commerce and Law were less likely to identify sexually transmitted disease, previous TOP and being underweight as contributory risk factors for miscarriage (aOR 3.39; 95% CI 1.77–6.51 and aOR 2.2; 95% CI 1.13–4.25 and aOR 2.79; 95% CI 1.10–7.03). Students from Engineering and Food Science were less likely to identify night work as a risk factor, but were more likely to consider stress as a contributory risk factor for miscarriage compared to Medicine and Health students (aOR 2.06; 95%CI 1.08–3.93 and aOR 0.36; 95% CI 0.13–0.98). The odds of not identifying oral contraceptive as a cause of miscarriage were lower for students who overestimated the rate of miscarriage compared to those who correctly identified the rate (OR: 0.30; 95% CI 0.12–0.75). Finally, only students from Arts and Social Science were more likely to identify heavy lifting as a risk factor.

Discussion
Main findings
This cross-sectional study provides insight into university students’ awareness of prevalence and risk factors of miscarriage. The findings of this study illustrate that common misunderstandings still prevail regarding the aetiology of miscarriage, suggesting a deficiency in formal information and access to information related to reproductive health. For example, only 20% of the students correctly identified the prevalence of miscarriage at 20%, and almost 30% incorrectly believed the prevalence of miscarriage is less common than 10%. Female students were more likely to identify the correct rate, but also to overestimate it, and male students tended to underestimate it. Almost one-quarter of the students believed miscarriage can happen from conception until birth, and 87% of the students erroneously selected the weeks of gestation at which miscarriage occurs. Females students, older students, those from Medicine and Health, those who were aware of a celebrity who had a miscarriage, and those who identified the correct rate of miscarriage were more likely to identify chromosomal abnormalities as the most common cause of miscarriage. However, this was only identified by 43% of the total sample.

Strengths and limitations
The nature of the study design implies that data were collected at one point in time. Previous studies have found an association between ethnicity and religion and the perception of risk factors for miscarriage [25], however we did not include this information in our survey and no comparison can be made. One of the main limitations is that a higher percentage of female students responded to the survey compared to male students. Although similar gender distributions were reported at UCC in the academic year 2006/2007 (36% male and 64% females) [26], recent overall data shows a more equal gender distribution for third-level graduates in the Republic of Ireland in 2016, with 52.2% of the students being female [27]. This percentage is similar to the European Union (EU-28) in 2015 [28]. Nevertheless, our sample seems to be representative of the overall distribution of male and females by discipline. In 2016, women represented more than three out of four (76.4%) graduates in Health, and more than four out of five (82.4%) graduates in Engineering were male [27] in the Republic of Ireland.

No standardised instrument of relevance was found in the literature for the purpose of this study; and therefore our survey was not validated. A multidisciplinary team specialised in pregnancy loss developed and reviewed all questions. In addition, a patient advocate for women who experience pregnancy loss also reviewed the questionnaire to ensure clarity. To our knowledge, this is one of the largest studies exploring the knowledge of rates and risk factors for miscarriage among college students from multiple disciplines, representing the main strength of this study.

Comparison with other studies
Our study is in keeping with the results of two previous studies [25, 29]. In a cross-sectional study including 1084 adults located in 49 states within the United States, Bardos et al. found that half of the participants believed that miscarriage was uncommon, occurring in 5% or less of all pregnancies. Similar to our results, it also found that approximately one fifth of the respondents incorrectly believed that lifestyle behaviours such as consumption of drugs, alcohol or tobacco were the only cause of miscarriage. In addition, men were more likely to identify lifestyle behaviours as a contributing risk factor for miscarriage. Also, participants with a higher educational degree identified chromosomal abnormalities more frequently as a cause of miscarriage compared to less educated respondents [25]. It is important to note that approximately 80% of these participants attended some college or medical school. Interestingly, in our study, male students were also more likely to identify smoking as a contributing risk factor. In another study, Delgado et al. assessed awareness among undergraduate students related to preconception health and pregnancy. Results showed a low to moderate level of awareness, with women having a slightly higher awareness than men [29].

Assessing the reasons behind overestimating or underestimating the risk of miscarriage is difficult to understand [30]. It could be possible that students who overestimate the risk of miscarriage were under
unnecessary stress or anxiety at the time of this study. Some studies have shown a link between psychological distress and anticipatory representations of possible future threats or overestimating the risk of a disease [31, 32]. No studies have evaluated college students’ psychological and lifestyles factors and perception of risk of pregnancy loss; therefore, more research needs to be done to assess which are the underlying factors that might impact on population’s perception of risk of pregnancy loss.

Implications
Despite the high occurrence of miscarriage, some studies highlight the potential barriers that might influence the lack of awareness of this topic among the general public. For example, the existence of guilt, shame or feeling responsible for the pregnancy loss might have reinforced the reclusion of the topic exclusively to the close family or friends, or in some cases, only among the couple who experience miscarriage [33, 34]. This has led to miscarriage being a “taboo” or “unspoken” topic in some cultures, increasing the chance of the causes of miscarriage being surrounded by myths and folklore [25, 35]. The potential benefits of promoting healthy behaviours, lifestyle, mental and social factors during women and men’s reproductive years has been increasingly accepted in the medical and scientific community [13, 36]. In this context, preconception health care is a unique opportunity to increase personal responsibility and awareness of risk factors and adverse pregnancy outcomes during the reproductive years of this targeted population [16].

Universities are underused settings for improving preconception health among the community. They provide an opportunity to reach a population with a diverse socioeconomic and gender background. In a scoping review of 29 preconception health care interventions evaluations, six of them were delivered at a School, college or university settings [17]. All of them reported an improvement in preconception health knowledge [29, 37–40]; however, most of the interventions were provided to women who were identified as being at-risk of developing adverse maternal outcomes, and men were not generally included in the interventions [37]. Although the Republic of Ireland has one of the highest birth rates in Europe [41], to our knowledge, there are no preconception healthcare intervention programmes or clinical practice guidelines focused on improved preconception healthcare in higher education settings.

Conclusion
According to our results and the little evidence available, misunderstanding of causes and risk factors for miscarriage is a public health issue. The findings of this study highlight an opportunity for public health interventions to improve reproductive health education. Universally preconception healthcare programmes successfully provide health promotion strategies to increase awareness of potential adverse outcomes in pregnancy. In particular, University settings are an ideal opportunity to reach a targeted population.

Ethical approval and consent to participate
This study received ethical approval from the Clinical Research Ethics Committee of the Cork Teaching Hospital on ECM 6 (rrrr) 120/416. Consent to participate was implied through completed surveys.

Funding
This study was supported by departmental funding. This research received no specific grant from any funding agency in the public, commercial or not-for-profit sectors.

Availability of data and materials
The datasets generated and analysed during the current study are not publicly available but are available from the corresponding author on reasonable request.

Authors’ contributions
JS, RR, SM and KOD conception and designed of the survey. JS obtained the data and ISLC analysed them. ISLC and SM interpreted the data. The questionnaire was anonymous and data were only accessed by the authors involved in the study. We confirm that all authors included in this study participated in the drafting and have approved the manuscript for submission. This manuscript has not been published and is not under consideration for publication elsewhere. We have no conflicts of interest to disclose.

Consent for publication
Not applicable.

Competing interests
The authors declare that they have no competing interests.
