ABSTRACT

Background

Introduction: Herlyn-Werner-Wunderlich syndrome is a rare congenital disorder that consists of a didelphic uterus, hemivaginal septum, and unilateral renal agenesis. Both diagnosis and management can be challenging in low-income countries.

Case presentation: a 13-year-old female who experienced recurrent pelvic pain, dysmenorrhea, and abdominal mass for one month. We could not obtain the MRI as it was unavailable in our hospital, and the patient cannot afford its expensive cost in a private center. Instead, US showed an absent right kidney and doubled uterus with a heterogeneous cystic formation. A pelvic CT scan revealed an absent right kidney, an enlarged left kidney, a double uterus, and a left hematocolpos. We established the diagnosis of Herlyn-Werner-Wunderlich syndrome and started planning for correcting the anomalies via laparotomy.

Discussion: ultrasound detects uterus didelphys, hematocolpos, hematometrocolpos, and renal agenesis but cannot identify the vaginal septum and the type of müllerian defect. The MRI is more convenient for a thorough assessment, but it is a high-priced diagnostic method.

Conclusion: although MRI is the gold standard for establishing the diagnosis and preoperative planning, ultrasound and CT scan can be an alternative, less expensive, and reliable approach. In addition, Laparoscopy or vaginoscopy may not be available in these countries. Therefore, correcting the anomalies can be achieved with laparotomy, which results in acceptable outcomes without any complications.

Herlyn Werner Wunderlich syndrome is a rare congenital disorder of müllerian ducts [1]. It is first reported in a 16-year-old patient in 1922 [2]. The etiology is unknown, but it implies a failure of the müllerian ducts to fuse during embryogenesis [1,3]. Furthermore, genetic and environmental factors may affect embryogenesis. Its incidence varies between 0.1 and 3% [3]. Herlyn Werner Wunderlich syndrome is defined by the classic triad: a didelphic uterus, hemivaginal septum, and unilateral renal agenesis [1]. However, cases have been reported without renal agenesis [4].

MRI is the cornerstone for the diagnosis as it can provide a comprehensive appraisal of müllerian abnormalities and help in preoperative planning [5,6]. However, it is an expensive diagnostic method [6,7]. The 2D ultrasound and CT scan may present an alternative approach to confirm the diagnosis [1,8]. Ultrasound exposes uterus didelphys, hematocolpos, hematometrocolpos, and renal agenesis [5]. Therefore, ultrasound may be sufficient to establish the correct diagnosis and begin treatment [9]. Management of Herlyn Werner Wunderlich syndrome based on drainage of the hematocolpos and resection vaginal septum, either through laparoscopy or vaginoscopy [7,10].

Herein, we present an alternative approach that depends on ultrasonographic and CT scan findings to diagnose Herlyn Werner Wunderlich syndrome in low-income countries. Moreover, while vaginoscopy or laparoscopy may be unavailable in these countries, we describe the management with laparotomy while preserving the hymen.

This manuscript has been reported in line with SCARE’s 2020 Criteria [11].
1. Presentation of case

A 13-year-old girl is brought to our department by her parents complaining about periodical pelvic pain for the last month accompanied by dysuria and polyuria. She did not report any fever, vomiting, or diarrhea. Her first menstruation was at 12 years; since then, it was regular but lasted for two or three days with scanty menstrual blood; and was associated with abdominal discomfort. A previous doctor prescribed her some analgesics to relieve her symptoms, but recently the pain became more severe with no response to medications. She was born at term without any complications, had no family history of congenital diseases, and her medical and surgical history was unremarkable. Her developmental milestones and external reproductive organs were conventional.

At admission, she was afebrile, and her vital signs were in the normal range. On physical examination, she had a mild pallor. We palpate a tender, mobile, painless mass on the left flank. Lab examination showed an elevated white blood cell count (13.3 × 10^3/μl: granulocytes: 93.6%; lymphocytes: 4.5%) and microcytic anemia (red blood cell: 4.86 × 10^6/μl, hemoglobin: 10.4 g/dl, hematocrit: 34.5%, MCV: 71.0 fl). Creatinine and urea levels were normal (1.1 mg/dl and 17 mg/dl, respectively). Albumin levels were within the reference range (4.9 g/dl). The 2D ultrasound showed an absent right kidney, a doubled uterus with a heterogeneous cystic formation measures 110 × 63 × 60 mm in the left cervix compressing the lower portion of the ureter resulting in second-degree left hydronephrosis; an enlarged left kidney (49.2 × 49.3 mm) with dilated renal pelvis and calyces; mild decreased in the cortical thickness (6.9 mm). We could not obtain the MRI as it was unavailable in our hospital, and the patient cannot afford its expensive cost in a private center. Instead, a pelvic CT scan was obtained and revealed an absent right kidney, an enlarged left kidney measures 49.2 × 49.3 mm (Fig. 1), and a double uterus (Fig. 2) with left cervical hematocolpos measures 110 × 63 × 60 mm in diameter (Fig. 3).

Our final diagnosis was Herlyn Werner Wunderlich syndrome which is complicated with hydronephrosis. Although hysteroscopy is a less invasive approach, it was unavailable in our department. We explained to her parents that laparotomy is a more invasive procedure, and they gave their informed consent. She underwent a laparotomy under general anesthesia. We opened the abdomen with a Pfannenstiel incision. We observed severe adhesions between the intestines and the peritoneum and around the uterus, fallopian tubes, ovaries, and bladder. We excised the adhesions using electrocautery. Laparotomy showed two separate infantile vaginas. The entire left genital tract was constant, but the right one exposed a right, transverse vaginal septum with an enlarged vagina (20 × 9 cm) containing chocolate-colored blood. A mildly dilated left
urinary tract defects; regarding the adjacent origin of both the meso
uterus didelphys is associated with a transverse vaginal septum.

categories, agenesis/hypoplasia; defects of vertical fusion; defects of
cavities exist separately [12].

nephric and paramesonephric ducts [9,12]. Renal abnormalities are
has reported a 100% prevalence of a vertical septum [4]. In our case, the
vertical or transverse vaginal septum exists [12], whereas another study
– lateral fusion [13]. Herlyn Werner Wunderlich syndrome represents a

septum had receded, exposing the uterine cavity [12]. Once the müller-
ian ducts fail to merge, the uterine horns, cervices, and endometrial
cavities exist separately [12].

In 1981, Müllerian duct abnormalities were classified under three
categories, agenesis/hypoplasia; defects of vertical fusion; defects of
lateral fusion [13]. Herlyn Werner Wunderlich syndrome represents a
failure of lateral and vertical fusion [9]. The etiology is unclear, but
environmental and genetic factors may influence embryogenesis [3].

Uterus didelphys is a rare müllerian duct anomaly developed in
5–7% of all cases [12]. Studies revealed that in 75% of cases, either a
vertical or transverse vaginal septum exists [12], whereas another study
has reported a 100% prevalence of a vertical septum [4]. In our case, the
uterus didelphys is associated with a transverse vaginal septum.

Paramesonephric duct anomalies are usually associated with upper
urinary tract defects; regarding the adjacent origin of both the meso-
nephric and paramesonephric ducts [9,12]. Renal abnormalities are
twice as frequent on the right side as they are on the left. However, renal
agenesis is the most frequent anomaly [8,12]. Horseshoe kidney, pelvic
kidney, multicystic renal dysplasia, and ectopic ureters are uncommon
[8]. A review of 49 patients reported renal anomalies in 10 patients;
eight patients had renal agenesis with ipsilateral obstructed hemivagina;
one patient had bilateral malrotated kidneys with complete obstructed
hemivagina; one patient had lobulation of the kidney [4]. Only one

2. Discussion

The reproductive system of both genders during the first six weeks is
similar and consists of two sets of paramesonephric and mesonephric
ducts. In females, the mesonephric ducts regress while the para-
mesonephric ducts fuse at their distal end to yield the uterus, cervix, and
upper two-thirds of the vagina; and persist uncombined near its prox-
imal part to generate the fallopian tubes. By the 12th week, the dividing
septum would reach, exposing the uterine cavity [12]. Once the müller-
ian ducts fail to merge, the uterine horns, cervices, and endometrial
cavities exist separately [12].

Among 45 patients who had undergone laparoscopy or laparotomy,
seven had endometrioses. Endometriosis was spread on the pelvic serosa
in four patients and located on the ovary in three, resulting in adhesions
[4]. Furthermore, few cases have reported acute urinary retention and
hydrenephrosis as late complications for Herlyn Werner Wunderlich
syndrome [15,16].

Patients with a didelphic uterus may have concerns about their

Most patients present during puberty on months up to one year after
menarche [3,5]. Studies have shown that the mean age of menarche was
12.5 years [4], and the mean age of diagnosis is 14.5 years [7]. There-
fore, many factors may postpone the accurate diagnosis; the patient has
regular menstrual periods from the unobstructed horn; because this is a
rare disorder, the physician would not include it in his differential di-
agnoses; the physician will usually prescribe an anti-inflammatory
medication to alleviate the patient’s symptoms. All of these factors
have a role in our delayed diagnosis of Herlyn-Werner-Wunderlich
syndrome [7].

The most frequent symptoms are periodical abdominal pain,
dysmenorrhea, and pelvic mass subsequently due to the obstructed
hemivagina [3,5]. A review of 49 patients reported that obstructed
hemivagina was observed in nine (18%) patients, of which six had a total
obstruction resulting in hematocolpos. The symptoms of complete
obstruction were abdominal mass, lower abdominal pain, and dysmen-
orrhea, similar to our patient’s. In contrast, incomplete obstruction ex-
hibits intermittent mucopurulent discharge [4]. These data revealed
that the obstructed hemivagina was associated with a didelphic uterus in
18% of cases and obstructed hemivagina and didelphic uterus report a
100% prevalence of renal agenesis to correlate to the side of obstruction
[4], as in our case as well. Moreover, dysmenorrhea was the most
frequent symptom and has arisen in 30 patients (71%) [4].

We used the US and CT scan as they can confirm the diagnosis [1,8].
Ultrasound detects uterus didelphys, hematocolpos, hematome-
trocolpos, and renal agenesis but cannot identify the vaginal septum and
the type of müllerian defect [5]. The MRI is more convenient for a
thorough assessment [5], but it is a high-priced diagnostic method [7].
Therefore, ultrasound may be sufficient to establish the correct diagnosis
and begin treatment [9].

The cornerstone of management is to resect the vaginal septum and
drain the hematocolpos via a vaginoplasty [5,7]. Scalpel, retractors, and
sutures might be helpful during the surgery. Pervading fluid permits for
thorough visualization of the obstructed vagina and the contralateral
pant cervix. It is feasible to conduct resection while keeping the hymen
intact. Some patients may have adhesions, abscesses, or endometriosis;
endometriosis among these patients is related to retrograde menstrua-
tion [7,8]. The complications related to the procedure include bladder or
rectum injury [7].

Among 45 patients who had undergone laparoscopy or laparotomy,
seven had endometrioses. Endometriosis was spread on the pelvic serosa
in four patients and located on the ovary in three, resulting in adhesions
[4]. Furthermore, few cases have reported acute urinary retention and
hydrenephrosis as late complications for Herlyn Werner Wunderlich
syndrome [15,16].
fertility and pregnancy [4]. Data have shown that 34 (94%) out of 36 women who wanted to conceive had at least one pregnancy and 32 (89%) of them had at least one living infant. However, preterm delivery, spontaneous abortion, and Cesarean section are prevalent among these patients [4].

3. Conclusion

Diagnosis and management of Herlyn-Werner-Wunderlich syndrome are very challenging in low-income countries. Although MRI is the gold standard for establishing the diagnosis and preoperative planning, ultrasound and CT scan can be an alternative, less expensive, and reliable approach. They reveal the three elements of this syndrome (didelphic uterus; hemivaginal septum; unilateral renal agenesis). In addition, Laparoscopy or vaginoscopy may not be available in these countries. Therefore, correcting the anomalies can be achieved with laparotomy, which results in acceptable outcomes without any complications.

Conflicts of interest

The authors declared that they have no conflict of interest.

Sources of funding

No funding is required.

Ethical approval

Ethical approval was not required.

Consent

Written informed consent was obtained from the patient’s parents for publication of this case report and accompanying images. A copy of the written consent is available for review by the Editor-in-Chief of this journal on request.

Author contribution

SJ collected the patient’s data. SJ, KT, and FR drafted the manuscript. NT and EA performed the procedure and revised the manuscript.

Registration of research studies

This is not an original research project involving human participants in an interventional or an observational study but a case report. This registration was not required.

Declaration of competing interest

The authors have no conflict of interest.

Acknowledgement

Not applicable.
