Abstract

Background

Hospitals serve as anchor institutions in many U.S. communities and make contributions to bolster population health and reduce preventable death. Most studies to date have focused on nonprofit hospitals, but there may be significant opportunity for for-profits to fill this role in both urban and rural communities.

Methods

We calculated descriptive statistics and a multivariate regression model to assess economic and health characteristics for all U.S. counties that contain for-profit as compared to nonprofit or public hospitals.

Results

For-profit hospitals are more likely to be located in counties with higher uninsurance rates and lower self-rated health. After controlling for hospital and county characteristics, we found a significant and positive relationship between for-profit hospital presence and higher county unemployment, higher uninsured rates, and the number of residents reporting poor/fair health. For-profit hospitals were also less likely to be located in states that had expanded Medicaid or which had certificate-of-need laws.

Conclusions

There is substantial opportunity for for-profit hospitals to serve as anchor institutions in many U.S. communities, despite this label more traditionally being applied to nonprofit hospitals. Given that there is not currently a regular reporting mechanism for documenting the community health contributions of for-profit hospitals, policymakers and researchers should evaluate the current state of these contributions and develop incentives to encourage more anchor activities to benefit economically vulnerable communities in the U.S.

Background:

Hospitals serve as prominent public health partners in U.S. communities and make contributions to bolster population health and improve economic conditions. These investments are vital to addressing health disparities and reducing preventable deaths (1). Although nonprofit hospitals are legally required to undertake population health activities, no data are available regarding the population health investments of for-profit or public hospitals. Given recently implemented reimbursement mechanisms, considerable incentives may encourage for-profit hospitals to invest in improving health in their surrounding communities. It is not clear, however, what the economic and public health impacts would be if for-profit hospitals directed more resources toward population health improvement.

The vast majority of hospitals currently operating in the United States are in the corporate form, meaning they are either privately owned nonprofit or for-profit hospitals. While government-funded public hospitals still comprise approximately 18.5% of the U.S. market, today nonprofits and for-profits control 81.5% of the American hospital market (2). Although more than half of hospitals nationwide are nonprofit, for-profit hospitals are growing in number and compose approximately a quarter of hospitals (2).

Hospitals have long been considered central to the welfare of a community, given their mission to provide acute medical services. However, hospitals also fill important nonmedical roles in both urban and rural communities (3–5). For example, hospitals frequently are the largest employers in their communities and are less likely than other businesses to leave the community and relocate elsewhere. For this reason, hospitals are often referred to as anchor institutions because they have strong potential to bolster economic development within communities and increase well-being (6,7).
An 'anchor institution' is a large institution - typically an educational, health, or other large corporation – that is not only deeply embedded within the economic infrastructure of a community, but also plays a role in improving community life, and in the case of hospitals, community health (8–13). Beyond job opportunities, anchor institutions invest in the social, economic, and health development of local communities as a significant part of their business models (10,13). Koh and colleagues describe anchors as institutions that "commit major financial, human, and intellectual resources to address social challenges, understanding that their future is inextricably linked to the community outside their walls" (10 p. 309). While hospitals in general have been discussed as having the potential to be anchor institutions (10,13), only nonprofits have been typically described as such (8). The result is that very little literature exists on the public health potential of for-profit institutions.

For-profit hospitals do have documented differences in comparison to nonprofits, and these differences may affect the potential for for-profit organizations to function as anchor institutions. For example, for-profit hospitals are more efficient in terms of employees, which may limit the numbers of jobs they provide to the local community (14). For-profits are also more likely to offer services that are profitable, as opposed to unprofitable but necessary, which may impact access to critical health care services in medically underserved settings (15–19).

Some scholars have argued that there are no significant differences in mission across for-profit and nonprofit hospitals and have questioned why most discussion of hospital anchors has focused on nonprofits in particular (20,21). There do not seem to be significant differences in the amount of uncompensated care offered by each hospital type (22–27), and there is evidence to suggest that for-profits serve a larger proportion of Medicaid patients, especially in rural markets (28).

Less is known about hospital decisions to enter health care markets and the distribution of for-profit vs. nonprofit hospitals in communities where institutional investments would have significant potential to elevate local population health. Regulatory and market changes, such as the introduction of the Medicare and Medicaid Prospective Payment System (PPS) in 1983, and ensuing changes to state and federal policy governing nonprofits and for-profits on a state by state basis, have created a mixed medical market in the U.S. that varies by state and region, with some states having more desirable markets for for-profits, such as Texas and Florida, and some states that do not have desirable, or open markets, for for-profits, such as New York, Maryland, and Vermont (18,19,29–31). There is evidence that for-profit hospitals may choose to locate in communities where there is less competition and better reimbursement rates (32) but more research is needed to understand the regional distribution of for-profit hospitals and the social and economic characteristics of the communities in which they are located.

The aim of this study, accordingly, is to understand if for-profit hospitals are located in unique social and economic environments as compared to their nonprofit and public hospital counterparts. This manuscript contributes to the existing literature in two key ways. First, the results will identify factors that increase the likelihood of hospitals of different ownership types operating in a county. Second, these results will provide insight into economic and health needs in the counties where different types of hospitals are located and will, as a result, illuminate the likely impacts of population health initiatives of for-profit hospitals in particular.

Methods:

Data:

Our data come from the United States Census American Community Survey, the Area Health Resource File and the American Hospital Association (AHA) Annual Survey. Community characteristics from all data sources are from the year 2017, while hospital characteristics are from 2018 data. The dataset also includes data on 2016 state certificate-of-need laws from the Mercatus Center at George Mason University (33) state Medicaid expansion data from the Kaiser Family Foundation (34) and purchasing power data sourced from the U.S. Census Bureau Current Population Survey and the Council for Community and Economic Research, congregated by advisorperspectives.com (35).

Sample

This study assesses characteristics as they relate to a hospital's presence in a county. The sample for the descriptive portion of the study consists of all U.S. hospitals and the counties within which they are located. The sample for the analytic portion of the
study consists of U.S. counties with general medical hospitals (excluding federal hospitals, but including other public hospitals). Counties with multiple general medical hospitals are observed multiple times in the sample. After accounting for missing data, the analytic sample for this study is 4,622 county observations. Eighteen hospitals were dropped because of missing county-level information, and one was dropped because of data missing on an AHA variable. For this reason, these observations were not included in the analysis.

Analytic strategy

In addition to the use of descriptive statistics, this study employs multivariate logistic regression. The key dependent variable for this analysis is the presence of a for-profit hospital within a county, considering county characteristics and hospital characteristics. We calculate the odds of a county containing a for-profit hospital in four individual models, each with a key county health or economic measure. Key measures include one health indicator, the percent of the population reporting poor or fair health, and three economic variables: unemployment, uninsured rate, and median per capita income. To offer a comparison between hospital ownership types, we further calculate the same models in relation to nonprofit hospital presence and then in relation to public hospital presence. The analysis also considers hospital characteristics (size, system membership, and teaching status), community and geographic characteristics (number of hospitals in county adjusted for population, percent of population white, and rural location), and policy characteristics (state has certificate-of-need regulation in place and status of Medicaid expansion) (measures described in Table 1).

[Table 1 about here]

**Results:**

Descriptive statistics identified 694 for-profit general medical centers, which account for 15% of the 4622 hospitals in the analytic sample. We identified 243 counties in the U.S. as having only for-profit hospitals, whereas 1,373 counties across the country have at least one non-profit hospital and no for-profit hospitals. The majority of counties with for-profit hospitals are also served by non-profit or public hospital facilities. As Fig. 1 shows, for-profit hospitals are not consistently distributed across the country and are instead concentrated in certain regions.

[Figure 1 about here]

The counties assessed in this study average a 5% unemployment rate; an 11% uninsured rate; and a 17% rate of reporting poor or fair health, with a median income (adjusted for purchasing power) of $55,000. However, counties with for-profit hospitals report higher averages in uninsurance rates (13%) and in reporting poor or fair health (18%) (Fig. 2). This gap between the means for the total sample and the for-profit hospitals’ counties widens when comparing nonprofit hospitals’ counties and for-profit hospitals’ counties. Descriptive statistics also indicated that counties with for-profit hospitals had, on average, a lower median income (adjusted for purchasing power) than those with nonprofit hospitals.

[Figures 2 and 3 about here]

Our multivariate analysis provides further understanding of the county characteristics associated with for-profit hospital presence (See Table 2). The analysis presented a significant relationship between for-profit hospital presence and higher county unemployment, higher uninsured rates, and the number of residents reporting poor/fair health. For-profit hospital presence was also significantly associated with lower median income (adjusted for purchasing power), though the effect for this variable was low.

For-profit hospitals have significantly lower odds of being in markets where there are more hospitals, of being in rural areas, or of being in regions outside the South. State regulations are also associated with for-profit hospital presence; for-profit hospitals have significantly lower odds of being in states with certificate-of-need laws or of being in states that have expanded Medicaid. Certain hospital characteristics were also significant, with for-profit hospitals having lower odds of being teaching hospitals or having 400 or more beds and higher odds of being a part of a multi-hospital system.

[Table 2 about here]

Discussion:

The aim of this study was to assess whether for-profit hospitals are more likely than other hospitals to operate in counties with significant health and economic needs. Our findings provide insights into the geographic distribution of for-profit hospitals and suggest that for-profit hospitals could have a disproportionate impact on population health if they engaged in population health investments in U.S. communities. Although previous research suggested that for-profit hospitals often seek out counties where they can hold significant market share and provide profitable healthcare services (16,18,28,36–38), we find that the majority of for-profit hospitals in the United States are located in counties where nonprofit hospitals are also operating. We do find important
regional differences, however, and observe lower for-profit presence in states that have certificate-of-need laws and that have expanded Medicaid.

At their core, both nonprofit and for-profit hospitals are privately held corporations, but much of the previous literature has focused on the potential contributions that nonprofits make to their local communities as a result of community benefit requirements in exchange for the tax exemption that these hospitals receive. For-profit hospitals, by contrast, pay taxes and may disperse their revenue streams to investors and leadership (39). However, our findings suggest that for-profits are likely to have an even greater opportunity to impact population health based on their location in counties with significant economic and health needs. Given higher rates of uninsurance and unemployment as well as lower income in counties containing for-profit hospitals, for-profit hospitals could or very well may serve as economic anchors in the same way as their nonprofit counterparts do: by providing jobs to local residents, by incentivizing their employees to live nearby and support the local economy, and through the acquisition of hospital supplies from local businesses (40).

Although data are not currently available to ascertain the specific investments that for-profit hospitals undertake to improve local population health, our findings underscore the potential for for-profit hospitals to greatly benefit the communities in which they are located and the need for better data on population health investments. Following previous research on community health investments, the tax status of hospitals may not be the only or most important factor in assessing their potential contributions to population health (16,17,29). Given that the effectiveness of community benefit laws for nonprofit hospitals remain disputed (30,41,42) policymakers might consider alternative mechanisms to both report the contributions that for-profit hospitals make to their surrounding communities (41) and incentivize anchor activities to reduce health disparities, especially in urban areas where for-profit hospitals are most likely to be located.

Limitations:

Our findings may be limited by the use of counties as a proxy for the community served by a hospital. While county statistics do provide context for the environment within which a hospital operates, a hospital’s primary service area may not reach the full county or may extend beyond it limiting our ability to understand what impact for-profit hospitals may have on the broader community. Because our data are cross-sectional, we cannot assess whether the presence of a for-profit hospital contributes to poor economic or health outcomes or whether for-profit hospitals may identify markets with these characteristics as better suited for their organizations.

Conclusion:

For-profit hospitals are disproportionately likely to be located in counties with significant economic and physical health needs. As such, there is substantial opportunity for for-profit hospitals to serve as anchor institutions in many U.S. communities, despite this label more traditionally being applied to nonprofit hospitals. Although for-profit hospitals do not have the same federal tax requirements to contribute to community health and well-being, there are significant financial incentives to contribute to population health improvement. Given that there is not currently a regular reporting mechanism for documenting the community health contributions of for-profit hospitals, policymakers and researchers should evaluate the current state of these contributions and develop incentives to encourage more anchor activities to benefit economically vulnerable communities in the U.S.

Figures
Figure 1

Title: Geographic distribution of for profit hospital beds in the US  
Legend: Using the percentage of beds in a county that were in for profit hospitals, this map indicates where for profit hospitals are most likely to operate. Darker colors on the map indicate a higher percentage of for profit beds.

| Percent poor/fair health | Unemployed | Uninsured | Percent poor/fair health |
|--------------------------|------------|-----------|--------------------------|
| Public general           | 4.54%      | 12.28%    | 17.60%                   |
| Nonprofit general        | 6.44%      | 9.49%     | 16.13%                   |
| Any hospital             | 4.47%      | 10.72%    | 15.83%                   |
| Any general medical      | 6.50%      | 10.68%    | 16.83%                   |
| For-profit general medical | 4.59%   | 13.15%    | 18.35%                   |
Title: County Characteristics Associated with Hospital Type

Legend: Using descriptive statistics, this figure shows whether different types of hospitals are located in counties with significant health and economic needs. For profit general medical centers are located in counties with higher unemployment, uninsurance, and poor/fair physical health than other hospital types.

Figure 3

Title: County Income Associated with Hospital Type

Legend: Using descriptive statistics, this figure shows the average county income (adjusted for purchasing power) where different types of hospitals are located. Counties with public hospitals have the lowest average income; counties with for profit hospitals have lower average income than counties with non profit hospitals.
