Arachidonic acid promotes skin wound healing through induction of human MSC migration by MT3-MMP-mediated fibronectin degradation

SY Oh¹,², S-J Lee¹,², YH Jung¹, HJ Lee¹ and HJ Han*¹

Arachidonic acid (AA) is largely released during injury, but it has not been fully studied yet how AA modulates wound repair with stem cells. Therefore, we investigated skin wound-healing effect of AA-stimulated human umbilical cord blood-derived mesenchymal stem cells (hUCB-MSCs) in vivo and its molecular mechanism in vitro. We found that transplantation of hUCB-MSCs pre-treated with AA enhanced wound filling, re-epithelization, and angiogenesis in a mouse skin excisional wound model. AA significantly promoted hUCB-MSCs migration after a 24 h incubation, which was inhibited by the knockdown of G-protein-coupled receptor 40 (GPR40). AA activated mammalian target of rapamycin complex 2 (mTORC2) and Aktζ through the GPR40/phosphoinositide 3-kinase (PI3K) signaling, which was responsible for the stimulation of an atypical protein kinase C (PKC) isoform, PKCζ. Subsequently, AA stimulated phosphorylation of p38 MAPK and transcription factor Sp1, and induced membrane type 3-matrix metalloproteinase (MT3-MMP)-dependent fibronectin degradation in promoting hUCB-MSCs motility. Finally, the silencing of MT3-MMP in AA-stimulated hUCB-MSCs failed to promote the repair of skin wounds owing to impaired cell motility. In conclusion, AA enhances skin wound healing through induction of hUCB-MSCs motility by MT3-MMP-mediated fibronectin degradation, which relies on GPR40-dependent mTORC2 signaling pathways.

Cell Death and Disease (2015) 6, e1750; doi:10.1038/cddis.2015.114; published online 7 May 2015

Skin wound healing is a dynamic process that involves inflammation, re-epithelization, granulation, vascularization, and tissue remodeling, in which various types of cells migrate into the wound. Many treatment modalities are applicable to improve skin recovery after injury including cytokines/growth factors and cell-based therapies. The use of stem cell therapy has been emphasized as a promising adjunct for delayed wound healing. In this process, the migration of stem cells is an important biological event to exert their beneficial effects which play a key role in cutaneous regeneration. Although commonly used approaches to manipulating stem cell behaviors include administration of biochemical cocktails and genetic modifications, these methods are considered impractical for clinical use owing to unexpected potential side effects. In this respect, the important factor for the success of stem cell therapy in cutaneous wounds is the capability to regulate stem cell behaviors with predictable methods. Therefore, the development of safe, effective, and practical means to modulate stem cell migration is a priority in the skin wound-healing field.

Many nutrients including lipid metabolites are receiving tremendous attention as emerging key regulators of stem cell behaviors. Current research on lipids and lipid metabolites has so far revealed a number of signaling pathways and effector molecules involved in cell functions, such as G-protein-coupled receptor 40 (GPR40), mammalian target of rapamycin (mTOR), and matrix metalloproteinases (MMPs). Interestingly, these signaling molecules are also closely related to stem cell behaviors. Thus, the specific effects of lipid metabolites on the regulation of stem cell functions are important in stem cell biology as well as stem cell-based therapy, which might differ by cell type, dosage, culture conditions, and metabolic state. To date, however, despite the fact that arachidonic acid (AA), a representative ω-6 polyunsaturated fatty acid (PUFA), is the second most abundant fatty acid released into a wound site during skin injury and implicated in the restoration of various types of tissues including intestine and bone, the functional role of AA in stem cell motility is not fully understood. Therefore, the complexity of AA-mediated regulatory networks in stem cell migration is both a challenge and an opportunity for further comprehensive investigations into stem cell-based skin wound therapy.

Mesenchymal stem cells (MSCs) have been shown to ameliorate wound healing in several studies. Human umbilical cord blood-derived mesenchymal stem cells (hUCB-MSCs) are characterized as neonatal stem cells which are abundant, convenient to obtain, capable of multilineage differentiation, and its molecular mechanism...
differentiation, and able to self-renew with a high proliferative capacity.\textsuperscript{19} Because hUCB-MSCs also retain a lower immunogenicity and higher migratory ability, their clinical potential has been assessed with cell-based applications for diseases including chronic skin wounds, colitis, and neurotmesis injuries.\textsuperscript{20–22} Thus, elucidating the role of AA in modulating behaviors of hUCB-MSCs is a promising and practical approach for clinical applications. Therefore, we investigated the role of AA in transplanted hUCB-MSCs for skin wound healing in vivo and its molecular mechanism in vitro.

Results

AA amplified both skin wound-healing capacity and motility of hUCB-MSCs. In order to evaluate the cutaneous wound-healing effect of hUCB-MSCs and AA, we grossly assessed wound closure and neovascularization in a mouse skin excisional wound model. The group transplanted with hUCB-MSCs pre-treated with AA showed the fastest wound closing (Figures 1a and b) and neovascularization (Figure 1c), while the control group treated with vehicle alone exhibited the slowest wound healing and few vessels. Intriguingly, addition of hUCB-MSCs+vehicle has stimulatory effect on wound closing and neovascularization, compared with the vehicle alone. However, our data revealed there was no statistical difference between AA alone and vehicle in angiogenesis, indicating AA alone did not show a significant enhancing effect on angiogenesis despite of its promoting effect on skin wound closure. This means that the wound healing induced by direct treatment of AA on wound bed is an independent mechanism of the angiogenesis that was initiated from hUBC-MSCs activated by AA. Thus, stem cells primed by AA appear to have specific modes of action that differ from ectopic application of AA in promoting the skin wound healing. Histological evaluation of skin wounds by hematoxylin and eosin (H&E) staining showed that the granulation tissue of wounds treated with AA or hUCB-MSCs did not make intimate contact with the surrounding tissue. In contrast, transplantation of hUCB-MSCs pre-treated with AA induced intimate contact of granulation and wound maturation (Figure 1d). The result of histomorphometric analysis revealed that the group transplanted with hUCB-MSCs pre-treated with AA has more hair follicle density in recovered skin tissue (Figure 1e).

For wound restoration, stem cell migration is a prerequisite for recruitment to the wound site.\textsuperscript{23} Thus, we investigated the effect of AA on hUCB-MSCs migration by treatment with various concentrations of AA for 24 h. AA statistically

Figure 1  AA enhances skin wound-healing effect of hUCB-MSCs. Two 6-mm wounds were made on the back of each ICR mouse, where we treated vehicle, AA, hUCB-MSCs + vehicle, and hUCB-MSCs + AA by topical application and intradermal injection. (a) Representative images of mouse cutaneous wounds on postoperative days are shown. (b) Open wound areas relative to the original wound size were quantified by using Image J program. (c) Representative images of neovasculature in wounds at day 9. Vessel densities relative to the group treated with vehicle alone were quantified by using Image J program (lower panel). (d) Representative H&E sections of wound tissues at day 9 are shown. (e) Hair follicle densities relative to the group treated with vehicle alone were quantified. (a–e) n = 5. Error bars represent the mean ± S.E. *P < 0.05, **P < 0.01. Scale bars = 100 μm.
enhanced the cell migration at 5 and 10 μM, but not at higher concentrations (Figure 2a). In addition, treatment with 10 μM of AA for various time periods promoted hUCB-MSCs migration in a time-dependent manner (Figure 2c). The same results were visually confirmed with scratch wound-healing assay (Figures 2b and d). To determine how much the AA-enhanced cell migration solely accounts for covering the mechanically denuded area in the migration assays, proliferation of the cells was evaluated with Mitomycin C, a cell cycle-arresting compound. The cell proliferation was found to increase much less compared with the cell migration (Figure 2e). Although the little effect of AA on hUCB-MSCs proliferation was seen in the result of cell counting (Figure 2f), the results after [3H]thymidine incorporation of hUCB-MSCs revealed that AA did not show any stimulatory effect on the cell proliferation (Supplementary Figure S1). We have performed additional experiments to check whether AA induces the differentiation of hUCB-MSCs in vitro. As shown in Supplementary Figure S2, however, the mRNA expression of differentiation markers for osteoblast (Runx2, Osteopontin), adipocyte (PPARγ, FABP4), chondrocyte (Sox9, Col2a1), and endothelial cell (VE-Cadherin, PECAM1) was not significantly regulated by 10 μM of AA treatment for 9 days, suggesting that 10 μM of AA treatment for 9 days seems not to be enough to initiate the differentiation of hUCB-MSCs. Importantly, AA did not have any significant effect on the expression of COX-1, COX-2, ALOX5, ALOX12, ALOX15, CYP4A11/22, and CYP2J2, which are major enzymes involved in AA metabolism (Supplementary Figure S3a). Moreover, the cell migration induced by AA was not regulated by pre-treatment with non-selective inhibitors for COX (indomethacin), LOX (NDGA), and CYP (1-ABT) (Supplementary Figure S3b), suggesting that...
hUCB-MSCs migration is truly attributed by AA itself, but not by AA metabolites. Interestingly, the AA-induced cell migration was abolished by transfection with small-interfering RNA (siRNA) for a membrane receptor for ω-6 PUFAs, GPR40, in an in vitro wound-healing migration assay (Figure 2g) and in an Oris cell migration assay (Figure 2h), indicating the involvement of GPR40 in AA-promoted hUCB-MSCs motility.

AA activates mTORC2, Akt<sup>ser473</sup>, and PKCζ through GPR40/PI3K signaling. We further examined whether the GPR40/PI3K/mTOR pathway is involved in promoting the motility of hUCB-MSCs. The phosphorylation of mTOR<sup>ser2448</sup> (mTORC1) and mTOR<sup>ser2481</sup> (mTORC2) induced by AA peaked at 30 min and 60 min, respectively (Figure 3a). We focused on the early-peaked mTORC2 which are present at

Figure 3  AA promotes phosphorylation of mTOR and Akt<sup>ser473</sup>. (a and d) hUCB-MSCs were incubated with 10 μM of AA for various time periods (0–90 min). Total proteins were extracted and blotted with mTORC1, phosphor-mTORC2, mTOR, phosphor-Akt<sup>ser473</sup>, phosphor-Akt<sup>thr308</sup>, or Akt. (b) Cells transfected with GPR40 specific siRNA (100 nM) were incubated with 10 μM of AA for 24 h and the levels of phosphor-mTORC2, mTOR, GPR40, and β-actin were examined by western blotting with total cell lysates. (c) Cells pre-treated with 10 μM of LY294002 for 30 min were incubated with 10 μM of AA for 30 min. Phosphor-mTORC2 and mTOR were detected by western blotting. (e) Cells were pre-treated with 10 mM of LY294002 for 12 h prior to AA exposure for 60 min. Phosphor-Akt<sup>ser473</sup> and Akt were detected by western blotting. Ten nano mole of Rapamycin (for 12 h), 10 μM of LY294002 (for 30 min), and 10 μM of Akt inhibitor I (for 30 min) were pre-treated to cells prior to 10 μM of AA incubation for 24 h. The inhibitory effect on the AA-enhanced hUCB-MSCs migration was examined in wound healing assay (f) and Oris cell migration assay (g). (a–g) n = 3. Data represent means ± S.E. *P < 0.05, **P < 0.01, ***P < 0.001. Scale bars = 100 μm (magnification × 100). Abbreviations: RFU, relative fluorescence units; ROD, relative optical density.
upstream signaling network compared with mTORC1.\(^{24}\) The AA-induced increase in phosphorylation of mTORC2 was significantly abrogated by transfection with GPR40 siRNA (Figure 3b) and by pre-treatment with PI3K inhibitor, LY294002 (Figure 3c). We then assessed phosphorylation of Akt closely associated with mTOR signaling. The phosphorylation level of Akt\(^{\text{ser473}}\) increased until 60 min in contrast to stationary Akt\(^{\text{thr308}}\) (Figure 3d). In addition, the phosphorylation of Akt\(^{\text{ser473}}\) was blocked by prolonged rapamycin pre-treatment, which is able to inhibit mTORC2 (Figure 3e).\(^{25}\) We also found that AA-induced cell motility was inhibited by LY294002, rapamycin, and Akt inhibitor I in an in vitro wound-healing migration assay (Figure 3f) and in an Oris cell migration assay (Figure 3g).

We further checked the involvement of PKC in signaling pathway induced by AA. The phosphorylation of PKC was detected from 60 to 120 min (Figure 4a). Among conventional (PKC\(\alpha\), novel (PKC\(\beta\), \(\epsilon\), and atypical (PKC\(\zeta\)) PKC isotypes, only atypical PKC\(\zeta\) translocated from the cytosol to the membrane in response to AA treatment (Figure 4b). The membrane translocation was visually confirmed by immunofluorescence staining in AA-treated hUCB-MSCs (Figure 4c). Because atypical PKC do not need calcium for activation, there was no calcium influx in AA-stimulated hUCB-MSCs (Figure 4d). In addition, the PKC\(\zeta\) activation was blocked by pre-treatment with Akt inhibitor I (Figure 4e) and rapamycin (Supplementary Figure S4a). We also found that AA-induced cell motility was inhibited by PKC inhibitor, Bisindolylmaleimide I in an in vitro wound-healing migration assay (Figure 4f) and in an Oris cell migration assay (Figure 4g).

AA promotes membrane type 3 (MT3)-MMP-mediated FN degradation through p38 MAPK/Sp1 cascade. We analyzed the phosphorylation level of MAPKs, which are major PKC substrates.\(^{26}\) AA uniquely induced phosphorylation of p38 MAPK from 60 to 120 min (Figure 5a), which was inhibited by pre-treatment with PKC inhibitor, Bisindolylmaleimide I (Figure 5b). But ERK and JNK were not stimulated by AA treatment. We then determined whether AA induces phosphorylation of Sp1, which is a ubiquitous transcription factor that controls gene expression involved in stem cell behavior.\(^{27}\) AA induced the phosphorylation of Sp1 from 6 to 12 h (Figure 5c) while no increase was observed before 6 h (data not shown). In addition, the nuclear translocation of Sp1 was observed at 6 h (Figure 5e), and both the phosphorylation and the translocation of Sp1 were blocked by pre-treatment with p38 MAPK inhibitor, SB203580 (Figures 5d and e). Furthermore, pre-treatment with PI3K inhibitor (LY294002) (Supplementary Figure S4b) and mTOR inhibitor (rapamycin) (Supplementary Figure S4c) also blocked the phosphorylation of Sp1 induced by AA. We also found that AA-induced cell motility was inhibited by SB203580 and Sp1 inhibitor, Mithramycin A, in an in vitro wound-healing migration assay (Figure 5f) and in an Oris cell migration assay (Figure 5g).

As Sp1 is responsible for the transcription of many MMP isotypes, which are crucial for cell migration,\(^{28}\) mRNA levels of MMPs were analyzed with real-time PCR. Among MMP isotypes expressed in hUCB-MSCs,\(^{29}\) AA distinctively increased the mRNA levels of MMP-12 and MT3-MMP, and decreased MMP-11 and MT1-MMP (Figure 6a). AA also increased the protein expression of MT3-MMP, but did not alter the protein level of MMP-12 (Figure 6b). Additionally, we observed the increased protein level of MT3-MMP in the both cytosol and membrane with western blotting and immunofluorescence staining (Figures 6c and d). Interestingly, we found that the gelatinolytic activity of MT3-MMP was enhanced by AA treatment (Supplementary Figure S5), suggesting that AA promotes the expression of MT3-MMP as well as its activity in hUCB-MSCs. The upregulation of MT3-MMP was abolished by Mithramycin A, an Sp1 inhibitor (Figure 6e). To determine the effect of MT3-MMP on extracellular matrix (ECM) degradation, we analyzed protein levels of FN and COLs, which are major components of ECM. Under a state of uniform expression of those proteins in whole-cell lysates, AA uniquely induced FN degradation from 12 to 24 h while there were no significant changes in COL 1, 3, and 5 in the medium (Figure 6f). By transfecting hUCB-MSCs with MT3-MMP siRNA, we observed the abolishment of AA-induced not just FN degradation, but also cell migration (Figures 6g–i).

AA-upregulated MT3-MMP stimulates the skin wound-healing effect of hUCB-MSCs. In experiments to determine whether AA-upregulated MT3-MMP contributes to the skin wound-healing effect of hUCB-MSCs, the hUCB-MSCs/MT3-MMPsiRNA transfectant model with gross evaluation at day 5 (Figures 7a and b). Furthermore, we found that hUCB-MSCs/NsRNA pre-treated with AA had a better effect than with the vehicle up to 20% at day 9 (Figures 7a and b). In addition, hUCB-MSCs/NsRNA pre-treated with AA induced more vessels around the wound, and the knockdown of MT3-MMP resulted in an inhibitory effect on angiogenesis in gross examination of neovascularization (Figure 7c). Histological evaluation of H&E-stained skin wounds showed that all groups (except for the hUCB-MSCs/NsRNA pre-treated with AA) had imperfect wound closure or granulation which did not make intimate contact with the surrounding tissue (Figure 7d) and had less hair follicle density in recovered wound area (Figure 7e). To evaluate how many transplanted cells migrated to the wound site for restoration, we counted 5-bromo-2‘-deoxyuridine (BrdU)-stained hUCB-MSCs at the site and found that the number of the hUCB-MSCs/NsRNA pre-treated with AA was more than that of the other groups by 70% (Figures 7f and g). In addition, we confirmed the majority of BrdU-labeled cells in wound tissues were not co-localized with endothelial cells marker, CD34, indicating that exogenous hUCB-MSCs did not seem to be differentiated into endothelial cells (Supplementary Figure S6).

Discussion

In the present study, we demonstrated that AA enhances skin wound healing through the induction of hUCB-MSCs migration in which AA stimulates GPR40 coupling with mTORC2 signaling to regulate MT3-MMP-mediated FN degradation (Figure 7h). We first found that AA by itself has the ability to aid cutaneous wound repair, suggesting that AA might amplify the
Figure 4  AA stimulates atypical PKCζ translocation. (a) hUCB-MSCs were treated with 10 μM of AA for different time periods (0–120 min). Total cell lysates were analyzed by western blotting using phospho-PKC and PKC antibodies. (b) Cells were stimulated with 10 μM of AA for 90 min and fractionated into cytosolic and membrane samples. Translocation of PKC isoforms were detected by western blotting and pan-cadherin was used as a control for plasma membrane. (c) Cells incubated with 10 μM of AA for 90 min were immunostained with PKCζ antibody (green). PI was used for nuclear counterstaining (red). The arrows point to translocated PKCζ in plasma membrane by AA. And the right graph presents distribution of PKCζ on the yellow lines in the merged images, which were analyzed by Fluoview 300 software (Olympus, Tokyo, Japan). Scale bars = 100 μm (magnification × 400). (d) Cells were loaded with 2 μM of Fluo-3/AM in serum-free medium for 40 min and treated with 10 μM of AA. Ca^{2+} influx was investigated by confocal microscopy and data are expressed as relative fluorescence intensity (F/F0%, arbitrary unit). A23187, a calcium ionophore, was used as a positive control. (e) Cells pre-treated with 10 μM of Akt inhibitor I for 30 min were incubated with 10 μM of AA for 90 min. And phospho-PKCζ and PKC were detected by western blotting. In (f) wound healing assay and (g) Oris cell migration assay, 5 μM of Bisindolylmaleimide I was pretreated to cells for 30 min before treating AA (10 μM) for 24 h, and then their inhibitory effect on the AA-enhanced hUCB-MSCs migration was examined. Scale bars = 100 μm (magnification × 100). (a, b, and e–g) n = 3. (c and d) n = 4. Data represent means ± S.E. *P<0.05, **P<0.01, ***P<0.001. Abbreviations: RFU, relative fluorescence units; ROD, relative optical density.
bioactivity of various migrating cells. Consistently, the transplantation of hUCB-MSCs, pre-treated with AA, was shown to accelerate skin regeneration through tissue re-formation and blood vessel supply. The majority of mesenchymal stem cells has been shown to enhance the angiogenesis via the paracrine mechanism rather than the multilineage differentiation.\textsuperscript{23} Thus, it is possible that AA induces motility of hUCB-MSCs to enhance the mobilization and recruitment of stem cells into wound site, where hUCB-MSCs activate paracrine mechanisms to promote vascular growth and angiogenesis.\textsuperscript{5,30} Therefore, our results suggest that the pre-activation of the hUCB-MSCs with AA could potentiate cell transplantation therapy not only with timely efficacy, but also with reduction of the side effects of overdose of AA.

**Figure 5** AA-induced phosphorylation of p38 MAPK is involved in Sp1 activation. (a) hUCB-MSCs were treated with 10 μM of AA at various time points (0–120 min). Total cell lysates were blotted with phospho-ERK, -JNK, -p38 MAPK, and their total form. (b) Cells pre-treated with 5 μM of Bisindolylmaleimide I for 30 min were incubated with 10 μM of AA for 90 min. And phospho-p38 and p38 MAPK were detected by western blotting. (c) Cells were exposed to 10 μM of AA for different times (0–24 h), and then total proteins were extracted and examined with phospho-Sp1, Sp1, and β-actin antibodies by western blotting. (d) Cells were pre-treated with 1 μM of SB203580 for 30 min prior to 10 μM of AA incubation for 6 h. And phospho-Sp1 and Sp1 were detected by western blotting. (e) Cells were treated with AA and/or SB203580 (the same manner used in Figure 5d) and fractionated into non-nuclear and nuclear samples. Translocation of Sp1 was blotted, and the Lamin A/C was used as a control for nucleus. In (f) wound healing assay and (g) Oris cell migration assay 1 μM of SB203580 and 5 μM of Mithramycin A were pretreated to cells for 30 min before treating 10 μM of AA for 24 h, and then their inhibitory effect on the AA-enhanced hUCB-MSCs migration was examined. (a–g) n = 3. Data represent means ± S.E. *P < 0.05, **P < 0.01, ***P < 0.001. Scale bars = 100 μm (magnification ×100).

Abbreviations: RFU, relative fluorescence units; ROD, relative optical density.
In addition, the pre-activation of UCB-MSCs with AA may offer a means of improving the potency of these cells without the need for additional cell numbers. It should be noted that the proper concentration of AA is critical to improve the outcome of stem cell treatment. In this study, we found that ≤ 10 μM of AA for 24 h was used for nuclear counterstaining (red). Scale bars = 100 μm (magnification x400). (c) Cells were pre-treated with 5 μM of Mithramycin for 30 min prior to 10 μM of AA exposure for 24 h. Then, total proteins were extracted and examined with MT3-MMP antibody by western blotting. (f) Cells were treated with 10 μM of AA for 24 h. Western blot assay of FN, COL-1, COL-3, and COL-5 on both cell lysates and proteins precipitated from medium by 30% trichloroethanoic acid was carried out. (g) Cells were transfected with MT3-MMP siRNA (25 nM) for 48 h prior to 10 μM of AA incubation for 24 h. And protein levels of FN both in cell lysates and in medium were analyzed with western blotting. In (h) wound healing assay and (i) Oris cell migration assay, MT3-MMP-specific siRNA (25 nM) were transfected to cells for 24 h prior to 10 μM of AA treatment for 24 h. And then, we examined the inhibitory effect of knockdown of MT3-MMP on the cell migration. Scale bars = 100 μm (magnification x100). (a-c and e-g) n = 3. (d) n = 5. (h and i) n = 4. Data represent means ± S.E. *P < 0.05, **P < 0.01, ***P < 0.001. Abbreviations: RFU, relative fluorescence units; ROD, relative optical density.

In the addtional, the pre-activation of UCB-MSCs with AA may offer a means of improving the potency of these cells without the need for additional cell numbers. It should be noted that the proper concentration of AA is critical to improve the outcome of stem cell treatment. In this study, we found that ≤ 10 μM of AA stimulates hUCB-MSCs migration in a dose- and time-dependent manner, but ≥ 15 μM of AA gradually decreases the migration. A similar result was also reported in which self-renewal of neural stem/progenitor cells diminished over a specific concentration of AA (10 μM). These results show that the proper concentration of AA is crucial in stem cell-based therapy and that relatively large amounts of AA are a burden on adult stem/progenitor cells, which is closely associated with oxidative stress from lipid peroxidation. In this respect, AA levels are not just permissive for stem cell functions but also determinative for at least certain aspects of the functions.

Although the roles of ω-6 PUFAs in proliferation and angiogenic effect of stem cells have been well studied, the functional role of AA by itself in stem cell migration has not been elucidated. GPR40, a membrane receptor for ω-6 PUFAs, is known to govern neurogenesis, nutrient sensing...
in the pancreas, inflammatory condition of the skin, and even proliferation of embryonic stem cells.\(^9,34-36\) In contrast to a previous report showing that some \(\omega-6\) PUFAs could regulate cellular events by interacting with cytosolic effectors,\(^37\) we found that AA directly promotes stem cell migration via GPR40, suggesting that the GPR40 activation is the critical requirement in improving the bioactivity of hUCB-MSCs for skin wound healing. mTOR, a pivotal regulator of cell metabolism and behaviors, integrates both extracellular and intracellular signals,\(^38\) but the relationship between GPR40 and mTOR has not been investigated. In fact, our data revealed that GPR40-dependent activation of the PI3K/mTORC2/Akt\(\text{ser}^{473}\) pathway has a key role in AA-induced hUCB-MSCs migration. However, the Akt\(\text{thr}^{308}/\text{mTORC1}\) pathway was not involved in this process. These results are consistent with previous reports showing the distinctive role of mTORC1 and mTORC2.\(^{11,39,40}\) In those reports, the Akt\(\text{thr}^{308}/\text{mTORC1}\) cascade mainly controlled cell growth, whereas cytoskeletal re-organization related to cell motility was critically regulated by the mTORC2/Akt\(\text{ser}^{473}\) cascade. Moreover, we showed that mTORC2 has the capacity to stimulate mTORC1 through Akt\(\text{ser}^{473}\) activation. Thus, our results suggest that mTORC2 is not only a major signaling hub in controlling AA-mediated hUCB-MSCs migration, but also a unique AA sensor that receives signals transduced from GPR40. This is further supported by a previous report describing that nutrient/redox/mitogenic input modulates the involvement mTORC2 signaling in cell movement.\(^41\) To the best of our knowledge, this is the first study to show the relationship between GPR40 and mTOR. Our findings suggest that the physiological activation of mTORC2 may be required for proper skin wound healing and that further activation of other members of the mTORC2 signaling pathway may also be a viable strategy to influence skin recovery.

It was previously documented that lysophosphatidic acid or amino acids induce mTORC2-mediated phosphorylation of Akt\(\text{ser}^{473}\), PKCo, or PKCo5 for cell migration.\(^42,43\) In contrast, we revealed that AA stimulates atypical (a) PKCo through mTORC2/Akt\(\text{ser}^{473}\) activation in enhancing hUCB-MSCs motility. This discrepancy could be explained by that \(\omega-6\) PUFAs are potent aPKCo stimulators.\(^44\) Indeed, \(\omega-6\) PUFAs were reported to promote oligonucleotide internalization through aPKCo activation.\(^45\) Thus, our data show that
mTORC2 could transduce AA-induced signals to αPKCζ via Akt and PKCζ. Having shown the functional role of αPKCζ is hUCB-MSC migration induced by AA, we further studied the mechanism on how αPKCζ links to other key molecules in stem cell migration. Interestingly, AA through αPKCζ selectively induced p38 MAPK-dependent activation of Sp1, which has the potential ability to modulate cell migration in response to some PUFAs. However, both ERK and JNK were not stimulated by AA, suggesting a cell-specific role of AA in determining downstream targets. Our results are further supported by a previous report showing that AA regulates both p38 MAPK and ERK for transcriptional activation of the cAMP response element-binding protein (CREB) in driving vascular smooth muscle cell movement. Although MAPKs have been documented to be capable of controlling the transcriptional activity of Sp1, the activation of Sp1 occurred long after that of p38 MAPK. This result is probably due to O-glycosylation of Sp1 by p38 MAPK, which contributes to nuclear translocation in which Sp1 is phosphorylated.

Thus, our results indicate that Sp1 has an important role in hUCB-MSCs migration by receiving the unique AA signaling pathway. Here, we show for the first time that the addition of AA had beneficial effects, improving the quality of hMSCs generated from cord blood through AA-induced bioactive signaling molecules.

During wound regeneration, MMPs remodel the ECM, allowing the penetration of stem cells and blood vessels into the wound site for tissue repair. Although MT-MMPs have been reported to dissolve the basement membrane directly and promote adult stem/progenitor cell motility, their functional role in stem cell migration and their effects on skin wound healing have not been characterized. In the present study, we found that AA uniquely increases the level of MT3-MMP among all the isoforms of MMP to regulate ECM degradation. In contrast to our previous reports showing that secretory MMP-12 participates in the mobilization of hUCB-MSCs in response to some microenvironmental factors, we identified that AA exclusively upregulates MT3-MMP through Sp1 in promoting the motility of hUCB-MSCs. This implies that activation of MMPs is distinctly regulated by microenvironmental factors that affect the transcription of many MMP isotypes. Despite the fact that MT3-MMP could degrade FN and COL-3 among the ECM proteins, we found that MT3-MMP uniquely degraded FN, which is abundant during the stage of granulation and angiogenesis during wound repair. In fact, it has been documented that MT3-MMP modifies the pericellular ECM, allowing the cells to have more functional podia highly specialized for migration. The results highlight that MT3-MMP specifically mediates the motility of hUCB-MSCs induced by AA.

Consistently, we found that the silencing of the MT3-MMP in hUCB-MSCs pre-activated with AA failed to regulate stem cell motility, resulting in a significant delay in cell migration and wound healing despite the AA pre-treatment. This means that the phenotypic outcome of hUCB-MSCs induced by AA in vitro is well maintained during skin wound healing in mouse. As MT3-MMP is a membrane-bound metalloproteinase and not a secreted one, we thought that MT3-MMP itself does not directly regulate angiogenesis in vivo. Instead, MT3-MMP plays a critical role in promoting the motility of hUCB-MSCs.

AA promotes wound-healing effect of hUCB-MSCs
SY Oh et al

Thus, it is possible that MT3-MMP cleaves pericellular substrate including FN and collagen and could therefore allow cells to migrate into wound sites. These mean that AA controls surface restriction of MT3-MMP to specifically degrade FN in promoting the migration of stem cells into wound site where the hUCB-MSCs induce the angiogenesis via paracrine mechanism or enhance the skin wound healing with specific modes of action.

Taken together, our findings suggest that pre-activation of hUCB-MSCs would provide new methods for stem cell therapy in wound healing and contribute to rationally develop culture conditions with optimal AA concentration or AA-based intervention protocols that could lead to long-term cost-effective outcomes in hUCB-MSCs-based skin wound therapy. In conclusion, AA promotes skin wound healing through induction of hUCB-MSCs motility for which AA binding to GRPR40 stimulates the PI3K/mTORC2/akt/p38 MAPK/Sp1 cascade leading to MT3-MMP-dependent FN degradation.
24 h before transplantation; mice in two groups were transplanted with hUCB-MSCs/NTiRNA that were pre-treated with vehicle (group 5) or AA (group 6); and mice in the other groups were given hUCB-MSCs/MT3-MMP/siP Hansen RNA that were pre-treated with vehicle (group 7) or AA (group 8). We injected 1 × 10^6 hUCB-MSCs in 70 μl PBS containing 50% growth factor-reduced Matrigel (BD Biosciences, Franklin Lakes, NJ, USA) into the dermis at two sites around the wound and also topically spread 0.3 × 10^6 hUCB-MSCs in 30 μl PBS containing the same Matrigel onto the wound bed at day 0 and 5. After that, we put Tegaderm (3M, London, ON, Canada) around the wounds. Images of wounds were taken on days 0, 5, and 9 with a digital camera system (DS5, Nikon, Tokyo, Japan) at the same camera/subject distance (30 cm). The open areas of wounds at days 5 and 9 were measured using Image J program (NIH, Bethesda, MD, USA) and presented as percentage of the original wound size. The images of inner side of cutaneous wound sites were obtained to evaluate angiogenesis at day 9. The wound tissues were then embedded in O.C.T. compound (Sakura Finetek, Tannce, CA, USA), stored at −70 °C, cut into 6-μm-thick frozen sections by using cryosectioning machine, and mounted on SuperFrost Plus slides (Thermo Fisher Scientific, Rockford, IL, USA) for H&E staining and immunohistochemistry. For histophotometric analysis, the recovered skin regions adjacent to granulation tissue were evaluated at x100 magnification in H&E-stained sections. Hair follicles were counted and the relative hair follicle densities were presented as percentage of the group treated with vehicle alone or hUCB-MSCs/NTiRNA+Vehicle.

Wound-healing migration assay. hUCB-MSCs (4 × 10^4 cells) were seeded on low 35-mm dishes with silicone inserts (Ibidi, Martinsried, Germany) and cultured until the cells reach around 100% confluence in serum-containing medium. After serum starvation for 24 h, the inserts were removed to create a wound field. The cells were incubated additionally for 24 h with 10 μM of AA and visualized with an Olympus Fluoview 300 confocal microscope (Tokyo) with a x100 objective.

Oris cell migration assay. hUCB-MSCs (3 × 10^5 cells)/100 μl were seeded in each well of Oris plate (Platypus Technologies, Madison, WI, USA) and incubated for at least 24 h to permit cell adhesion. The cells were cultured until they reach around 70% confluence. After that, inserts were carefully removed and the cells were gently washed with warm PBS. The cells were incubated with 10 μM of AA in serum-free medium for 24 h and then treated with 5 μM of calcein AM for 30 min to stain the cell populations in endpoint assays. By using a microplate reader to measure excitation/emission wavelengths (485/515 nm), migrated cells were quantified.

Scratch wound-healing assay. hUCB-MSCs were cultured until 90% confluence in 35-mm dishes and scratched with a sterile cell scraper (Fisher Scientific, Pittsburgh, PA, USA). The border of the denuded area was marked with a fine line immediately, and the cells were incubated with 10 μM of AA in serum-free medium for 24 h. After that, the cells were gently washed with warm PBS. The cells were incubated with 10 μM of AA in serum-free medium for 24 h and then treated with 5 μM of calcein AM for 30 min to stain the cell populations in endpoint assays. By using a microplate reader to measure excitation/emission wavelengths (485/515 nm), migrated cells were quantified.

Measurement of calcium influx. Changes in [Ca2+]i were measured using Fluo-3-AM (Invitrogen Co., Carlsbad, CA, USA). Cells were incubated with 10 μM Fluo-3-AM for 40 min, rinsed, and scanned every second with confocal microscope (Fluoview 300, Olympus, Hamburg, Germany) at excitation/emission wavelengths of 488/515 nm. A23187, a calcium ionophore, was used as a positive control. All analyses of [Ca2+]i were processed in a single cell, and the results were expressed as the relative fluorescent intensity (RFI).

Cell counting. hUCB-MSCs (4 × 10^3 cells) were seeded per well and cultured until they reach around 70% confluence. After serum starvation for 24 h, cells were incubated with 10 μM of AA up to 48 h, and the number of cells was counted at different time points using a hemocytometer.

[3H]-thymidine incorporation assay. hUCB-MSCs were synchronized by culture in serum-free media for 24 h and then incubated with 10 μM of AA for 0–48 h. After the incubation period, 1 μCi of [methyl-3H]-thymidine (specific activity: 74 GBq/mmol; Amersham Biosciences, Buckinghamshire, UK) was added to the cultures for 1 h at 37 °C. Cellular [3H]-thymidine uptake was quantified by liquid
scintillation counting (Wallac, Turku, Finland) in harvested cellular material. All values were converted from absolute counts to percentages of control.

**Gelatin zymography.** Whole-cell lysate samples were resolved under non-reducing conditions on 10% SDS-PAGE gels embedded with 1 mg/ml gelatin. Gels were rinsed for 30 min each in buffer 1 (50 mM Tris, 2.5% Triton X-100, pH 7.5) and buffer 2 (50 mM Tris, 5 mM CaCl$_2$, 1 mM ZnCl$_2$, 2.5% Triton X-100, pH 7.5), and then incubated in buffer 3 (50 mM Tris, 5 mM CaCl$_2$, 1 mM ZnCl$_2$, pH 7.5) for 12 h at 37 °C. The gels were stained with Coomassie Blue, and areas of gelatinolytic visualization were visualized as transparent bands.

**MTT assay.** Cell viability was assessed by using the conversion of 3-(4,5-dimethyl thiazolyl-2)-2,5-diphenyl tetrazolium bromide (MTT) to formazan via visualized as transparent bands.

The mediums were then removed and cells were incubated with 150 μM MTT solution was added to each well for 3 h. The absorbance at 570 nm was recorded using a spectrophotometer.

**Statistical analysis.** All results are expressed as mean value ± standard errors (S.E.). All experiments were analyzed by ANOVA, and some experiments were evaluated by comparing treatment means to the control using the Bonferroni-Dunn test. Difference at P < 0.05 was considered statistically significant.
