ABSTRACT
Objectives: To determine whether a polymorphism in the Fcγ receptor type IIIA (FCGR3A-F158V), influencing immunoglobulin G binding affinity, relates to the therapeutic efficacy of rituximab in rheumatoid arthritis (RA) patients.

Design: Observational cohort study.

Setting: Three university hospital rheumatology units in Sweden.

Participants: Patients with established RA (n=177; 145 females and 32 males) who started rituximab (Mabthera) as part of routine care.

Primary outcome measures: Response to rituximab therapy in relation to FCGR3A genotype, including stratification for sex.

Results: The frequency of responders differed significantly across FCGR3A genotypes (p=0.017 in a 3×2 contingency table). Heterozygous patients showed the highest response rate at 83%, as compared with patients carrying 158FF (68%) or 158VV (56%) (p=0.028 and 0.016, respectively). Among 158VV patients, response rates differed between male and female patients (p=0.036), but not among 158FF or 158VF patients (p=0.72 and 0.46, respectively).

Conclusions: Therapeutic efficacy of rituximab in RA patients is influenced by FCGR3A genotype, with the highest response rates found among heterozygous patients. This may suggest that different rituximab mechanisms of action in RA are optimally balanced in FCGR3A-158VF patients. Similar to the previously described associations with RA susceptibility and disease course, the impact of 158VV on rituximab response may be influenced by sex.

INTRODUCTION
The growing arsenal of biological agents available in rheumatoid arthritis (RA) pharmacotherapy increases the demand for predictors of therapeutic responses and/or side effects. Human Fcγ receptors mediate effector functions of immunoglobulin G (IgG) antibodies and may modulate the therapeutic efficacy of all biological substances containing IgG-Fc parts. Hence, a functional single-nucleotide polymorphism in FCGR3A (FCGR3A-F158V, rs3909991), influencing IgG binding affinity to the activating Fcγ receptor type IIIA (FcγRIIIA),1 has been associated with the therapeutic efficacy of rituximab (RTX), that is, an anti-CD20 B cell-depleting IgG1 monoclonal antibody, in B cell
malignancies. RTX-coated B cells may be eliminated by several mechanisms; complement-dependent cytotoxicity, antibody-dependent cytotoxicity (ADCC) by natural killer (NK) cells, and/or phagocytosis by FcyR-bearing cells. Although the relevance in humans has not been established, mice lacking proper complement or NK-cell functions are equally well B cell depleted as native animals, thus pointing towards a major role of FcyR-bearing macrophages. It has been convincingly shown that RTX binds with higher affinity to 158V in an allele-dose-dependent manner and that ADCC and higher response rates to RTX.

Numerous case–control studies have been performed with regard to FCGR3A-F158V and RA susceptibility. Although initial studies showed remarkably discordant results, subsequent investigations have shown an association between homozygosity of the high-affinity allele (158VV) and an increased risk of RA in Europeans. In studies presenting data stratified for sex, the increased risk conferred by the 158VV genotype only was signiﬁcantly different between 158FF and 158VV.

The current study was conducted to explore the influence of FCGR3A genotype on RTX efﬁcacy in RA patients.

**PATIENTS AND METHODS**

Patients with established RA (n=177; 145 females and 32 males) who started RTX (Mabthera) as part of routine care at three rheumatology clinics in Sweden (Karolinska University Hospital, Solna; Linköping University Hospital, Linköping; and Umeå University Hospital, Umeå, Sweden) were included in the study. Baseline characteristics and concurrent medication are shown in table 1. The therapeutic response was assessed by the European League Against Rheumatism (EULAR) response criteria after 3–6 months. DNA was extracted from whole blood by standard techniques and FCGR3A-F158V was genotyped by a commercially available TaqMan assay (Applied Biosystems, Foster City, CA, USA, ID C_25815666_10). Validation of the TaqMan results was performed in 30 samples (10 of each genotype), yielding 100% concordance with a previously described direct sequencing assay specific for FCGR3A.7

**Table 1. Baseline characteristics of the 177 RA patients according to FCGR3A genotype**

| FCGR3A Genotype | 158VV (n=18) | 158VF (n=78) | 158FF (n=81) | Total (n=177) |
|-----------------|-------------|-------------|-------------|--------------|
| Mean (SD) disease duration, years | 11 (6) | 15 (10) | 14 (12) | 14 (11) |
| Females, n (%) | 13 (72) | 61 (78) | 71 (88) | 145 (82) |
| Rheumatoid factor positive, n (%) | 12 (67) | 62 (81) | 63 (78) | 137 (78) |
| Baseline DAS28, mean (SD) | 5.2 (1.0) | 5.5 (1.1) | 5.5 (1.2) | 5.5 (1.1) |
| Concurrent DMARD therapy, n (%) | 15 (83) | 48 (62) | 59 (73) | 122 (69) |
| Oral glucocorticoid therapy, n (%) | 13 (72) | 55 (72) | 48 (64) | 116 (69) |
| Number of previous TNF inhibitors, mean (SD) | 1.4 (1.2) | 1.3 (1.1) | 1.2 (1.1) | 1.3 (1.1) |

*Data available on: #76/78 patients, #75/81 patients, #169/177 patients.

**RESULTS**

Overall, 130 patients (73%) achieved a moderate or good EULAR response, whereas 47 (27%) were non-responders. The distribution of FCGR3A genotypes was 81 (46%) 158FF, 78 (44%) 158VF and 18 (10%) 158VV, which is in agreement with previous findings in Swedish RA populations, and in Hardy-Weinberg equilibrium (p=0.95). The proportion of EULAR good responders did not differ signiﬁcantly across FCGR3A genotypes (21%, 26% and 28% for 158FF, 158VF and 158VV, respectively). However, the proportion of good and moderate responders together, compared to non-responders, was signiﬁcantly different across FCGR3A genotypes (p=0.017 in a 3×2 contingency table), where heterozygous patients showed the highest response rate (65 of 78 patients, 83%), as compared to 55/81 (68%) patients carrying 158FF (OR 2.36, 95% CI 1.04 to 5.41, p=0.028), and 10/18 (56%) 158VV patients (OR 4.0, 95% CI 1.16 to 13.9, p=0.016; figure 1). The frequency of responders was not signiﬁcantly different between 158FF and 158VV.
response to RTX. Our study is, to our knowledge, the largest on this topic to date, and we surprisingly found a significantly larger proportion of responders among FCGR3A-158VV individuals, that is, FCGR3A-158VF.

A previous study on RA patients reported that the proportion of responders among 158VF patients was significantly higher compared to 158FF cases, but that the proportion of responders among 158VV were similar to 158VF, albeit failing to reach statistical significance when compared with 158VF or 158FF. Merging the response data from the two studies yields a significantly better response rate among 158VF as compared to 158FF, (OR 2.82, 95% CI 1.44 to 5.56, p=0.001), whereas the 158VV group does not differ significantly from neither 158VF (OR 0.41, 0.15 to 1.15, p=0.067) nor 158FF (OR 1.17, 95% CI 0.46 to 2.99, p=0.83).

Shortcomings of the current study include the fact that therapeutic response was assessed with up to 3 months variation between patients. However, a separate analysis of patients with response assessed at 6 months (n=108) yielded similar results, making a major impact of follow-up time-point unlikely. Our finding that 158VF patients less frequently experience response to RTX is discordant with the findings of Ruyssen-Witrand et al, and the limited number of 158VV patients (in both studies) adds uncertainty to firm conclusions regarding this particular genotype. Further, the relatively limited number of male patients calls for cautious interpretation of the findings regarding sex differences. Still, we believe that the 158VV sex difference is of interest, as no tendencies towards sex differences were found among 158FF and 158VF patients, despite being substantially larger groups. Also, there are previously described sex-dependent associations of 158VV

**DISCUSSION**

Although an influence of FCGR3A-F158V on RTX efficacy was in line with our hypothesis, the lack of a clear allele-dose effect points towards a more complex role of FCGR3A in RTX therapy of RA than anticipated. On the basis of previous reports of increased RTX-induced ADCC, more pronounced peripheral B cell depletion, better clinical outcomes in B cell malignancies, we expected any difference to appear in favour of the FCGR3A genotype and rituximab efficacy in RA understood. The initial view that the disease-modifying action of RTX depends on depletion of B cells and the eventual disappearance of pathogenic autoantibodies is contradicted by several observations. For instance, although circulating autoantibodies may indeed decline, they seldom disappear, and both non-circulating B cells and autoantibody production in the synovium are clearly less affected by RTX than their circulating counterparts. Other proposals for RTX mode of action in RA include the immune complex decay hypothesis, suggesting that RTX-opsonised B cells keep disease-promoting FcγR-expressing phagocytic cells busy eliminating B cells instead of perpetuating synovial inflammation. In this context, one would expect that the more pronounced activation of FCGR3A-158VV macrophages would render them less prone to divert from the immune complex-driven rheumatoid inflammation in the synovium, and hence corresponding to a worse therapeutic outcome in 158VV patients as seen in the current study. Alternatively, FCGR3A-158VV individuals could, as compared to FCGR3A-158FF, handle RTX-opsonised B cells more efficiently and may thereby, to a greater extent and more rapidly, return from this drug-induced diversion. Our finding of a significantly higher response rate among heterozygous patients could possibly point towards several mechanisms being involved in RTX action and that, in RA, these are most optimally balanced in individuals with the intermediate binding variant of FcγRIIA, that is, FCGR3A-158VF.
in RA.\textsuperscript{7,10} The FCGR locus is subject to copy number variation (CNV), and in the current study CNV of FCGR3A was not investigated. However, the functional consequences of FCGR3A CNV remains unknown, and a previous study showed that only 5\% of Swedish individuals carry \#2 copies of FCGR3A.\textsuperscript{18}

On the basis of currently available data, we conclude that FCGR3A-F158V heterozygosity is associated with a better response to RTX in RA patients as compared with homozygosity of the low-affinity F allele. Data regarding patients carrying two high-affinity alleles, 158V\textsuperscript{2}, remains inconclusive and needs to be resolved before FCGR3A-F158V may become clinically relevant as a predictor of RTX response in RA.
