NECESSARY STOCHASTIC MAXIMUM PRINCIPLE FOR DISSIPATIVE SYSTEMS ON INFINITE TIME HORIZON

CARLO ORRIERI AND PETR VEVERKA

Abstract. We develop a necessary stochastic maximum principle for a finite-dimensional stochastic control problem in infinite horizon under a polynomial growth and joint monotonicity assumption on the coefficients. The second assumption generalizes the usual one in the sense that it is formulated as a joint condition for the drift and the diffusion term. The main difficulties concern the construction of the first and second order adjoint processes by solving backward equations on an unbounded time interval. The first adjoint process is characterized as a solution to a backward SDE, which is well-posed thanks to a duality argument. The second one can be defined via another duality relation written in terms of the Hamiltonian of the system and linearized state equation. Some known models verifying the joint monotonicity assumption are discussed as well.

1. Introduction

The study of the stochastic maximum principle (SMP in short) is a current field of research motivated by the interest in finding necessary (and sufficient) conditions for optimality for stochastic control problems. The general idea of the SMP consists in associating to every controlled trajectory an adjoint equation which is backward in time. Its solution, called a dual process (which is, in fact, a pair of processes), is shown to exist under some appropriate conditions and plays a role of “generalised Lagrange multipliers”. The SMP is a variational inequality formulated by means of the state trajectory and the dual process. It is satisfied by any optimal control and, usually, adding some convexity assumptions, it fully characterizes the optimality. Moreover, if the control enters the diffusion, the irregularity in time of the noise forces to introduce a second adjoint process which is strictly related to the Lyapunov equation for the first variation of the state.

The first general formulation of the SMP is due to Peng [17] for finite dimensional systems. After this seminal work, there has been a large number of works on this subject, both in finite and infinite dimensions for different formulation of the control problem. SMP in infinite dimension has been studied e.g. in Tang and Li [21], Fuhrman, Hu and Tessitore [7], Du and Meng [5], Liu and Zhang [9] whereas some of the results in finite dimension comprise: Jump control: Tang and Li [21], Øksendal and Sulem [11]; Singular control: Bahlali and Mezerdi [1], Dufour and Miller [6], Øksendal and Sulem [12]; Impulse control: Wu and Zhang [23]; Delayed controlled systems: Øksendal, Sulem and Zhang [13]; Near-optimal control: Zhou [25] and many others.

This paper is a natural continuation of [10] on one side and [15] on the other. Our aim is to control the behaviour of a dissipative system in an unbounded time interval and to provide necessary conditions for optimality. If $W_t$ is a $d$-dimensional Brownian motion, the equation for the state can be written in the form

$$X_t = x + \int_0^t b(X_s, u_s) \, ds + \int_0^t \sigma(X_s, u_s) \, dW_s,$$

$\mathbb{P}$-a.s. for all $t \in [0, +\infty)$ and all $x \in \mathbb{R}^n$. The objective is to minimize a discounted functional

$$J(u(\cdot)) = \mathbb{E} \int_0^{+\infty} e^{-rt} f(X_t, u_t) \, dt,$$

1
over all admissible controls $u(\cdot)$ with values in a general separable metric space $(U, d)$. Let us remark that this general assumption on the space of control actions allows us to consider a broad class of controls, such as bang-bang controls, which are excluded from the classic convexity framework. On the other hand, it necessarily forces us to formulate the SMP via a spike perturbation argument.

The analysis of the problem is based on the well-posedness of the state equation under a joint (or global) monotonicity assumption. For any $x, y \in \mathbb{R}^n$ and fixed $p > 0$, there exists $c_p \in \mathbb{R}$ such that

$$
\langle b(x, u) - b(y, u), x - y \rangle + p\|\sigma(x, u) - \sigma(y, u)\|^2 \leq c_p|x - y|^2, \quad \forall u \in U,
$$

where $U$ is the space of control actions. For a detailed exposition of SDEs with this property see [3]. This condition is a generalization of the usual dissipativity condition which involves only the drift of the equation and allows us to consider a larger class of concrete examples. Informally, there is a balance between the dissipativity of the drift and the noise term. If the drift term is dissipative enough, the diffusion term can grow in a polynomial way, instead of being globally Lipschitz. As a reference for this general assumption, see [3] and [19]. A list of several important examples satisfying joint monotonicity condition is given further in this paper. However, let us notice that many interesting equations do not satisfy a global monotonicity assumption (see [4] for a selection of examples) and the formulation of a version of the SMP for these systems could be a subject of a future work.

In the first step of our analysis we have to deal with a partially-coupled system of the state equation and the first adjoint equation. The delicate question here consists in giving a precise meaning to the solution of the following backward SDE

$$
dp_t = -\left[D_x H(\bar{X}_t, \bar{u}_t, p_t, q_t) - r p_t \right] dt + q_t dW_t,
$$

where $H(x, u, p, q) = \langle p, b(x, u) \rangle + \text{Tr} [q^T \sigma(x, u)] - f(x, u)$ is the Hamiltonian of the system and $(\bar{X}, \bar{u})$ is an optimal pair.

In general, the behaviour at infinity of BSDEs is not easy to understand and different approaches and approximations are proposed in several papers. In our setting, we are able to tackle the problem showing that the adjoint equation preserves, in some sense, the dissipativity of the state. Using a duality argument and the same technique as in [18] we can show that there exists a solution in some exponentially weighted space. It turns out that for the analysis of the state and adjoint equations the condition on the discount factor (forming both the functional and the weight $e^{-rt}$ in the definition of exponential weighted space) is given by some formula in terms of the joint monotonicity constant $c_p \in \mathbb{R}$. Nevertheless, due to the framework of SMP (use of the spike variation techniques) and, more importantly, due to the form of the polynomial growth assumption one has to assume implicitly $r$ positive so that the polynomial bound is integrable with the weight.

As already mentioned, the presence of the control in the diffusion term makes a second adjoint process to appear. In this case, there exists a formal matrix-valued BSDE which represents the process, but due to the lack of dissipativity of the equation, it seems to be impossible to obtain an a priori estimate of the solution. To solve the problem we follow the idea of Fuhrman et al. in [4] and we define the first component of the second adjoint process $P_t$ as a bilinear form defined via the relation

$$
\langle P_t, \gamma \rangle := \mathbb{E}^F \int_t^\infty e^{-r(s-t)} \langle D^2_x H(\bar{X}_s, \bar{u}_s, p_s, q_s) y_s, y_s \rangle ds,
$$

where $(y_{s}^{t, \eta})_{s \geq t}$ is the solution of the linearized state equation starting from $\eta$ at time $t$. Note that the second component $Q_t$ does not appear in the definition of the SMP. Proceeding this way it is not necessary to define and solve the second adjoint equation (i.e. finding the couple $(P, Q)$) but it is sufficient to identify only the process $P$ via the equality [4]. Notice that our definition of $P$ is similar to the notion of transposition solution presented in [3]. Nevertheless, if the diffusion term $\sigma$ is Lipschitz, $P$ can be indeed identified as a unique solution to a matrix-valued BSDE which, in fact, inherits the monotonicity property from the state equation. The formulation of the SMP, in this case, follows by similar arguments as in [13] but with an extension to the infinite horizon setting.

Having in mind the form of the Hamiltonian of the system, the final step (and the main result, Theorem [5]) is to derive a necessary condition for optimality. Let us suppose that $(\bar{X}, \bar{u})$ is an
optimal pair, then for every \( v \in U \), the following variational inequality has to hold \( \mathbb{P} \otimes dt - \text{a.e.} \)

\[
H(\tilde{X}_t, v, p_t, q_t) - H(\tilde{X}_t, \tilde{u}_t, p_t, q_t) + \frac{1}{2} \sum_{j=1}^{d} \left( P_t \left( \sigma^j(\tilde{X}_t, v) - \sigma^j(\tilde{X}_t, \tilde{u}_t) \right), \sigma^j(\tilde{X}_t, v) - \sigma^j(\tilde{X}_t, \tilde{u}_t) \right) \leq 0.
\]

This variational inequality can be rewritten in terms of so called \( \mathcal{H} \)-function defined by

\[
\mathcal{H}(x, u) := H(x, u, p_t, q_t) - \frac{1}{2} \text{Tr}(\sigma(\tilde{X}_t, \tilde{u}_t)^T P_t \sigma(\tilde{X}_t, \tilde{u}_t)) + \frac{1}{2} \text{Tr}[(\sigma(x, u) - \sigma(\tilde{X}_t, \tilde{u}_t))^T P_t (\sigma(x, u) - \sigma(\tilde{X}_t, \tilde{u}_t))],
\]

in the following manner

\[
\mathcal{H}(\bar{X}_t, \bar{u}_t) = \max_{v \in U} \mathcal{H}(\tilde{X}_t, v), \quad \mathbb{P} \otimes dt - \text{a.e.}
\]

The paper is organized as follows. The second and third sections contain the basic assumptions, the formulation of the discounted problem and a list of motivating examples. In section 4, we study well posedness of the state equation. The fifth section concerns with the application of the spike variation technique to our problem. In the two next sections, 6 and 7, the two adjoint processes are studied. The first adjoint BSDE is solved by approximation and a duality argument whereas, the construction of the process \( P \) is described without any potential relation to some BSDE. A precise statement of the main theorem (Theorem 5) is presented in section 8 and its proof is given. Last, in the Appendix we provide some technical proofs and we quote the actual restriction for the discount factor including the final one used in formulation of the main result.

## 2. Assumptions and Preliminaries

Let \( W = \{W_t^1, \ldots, W_t^d\}_{t \geq 0} \) be a standard \( d \)-dimensional Brownian motion defined on some complete filtered probability space \((\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P})\). The filtration \((\mathcal{F}_t)_{t \geq 0}\) is assumed to be the canonical filtration of \( W \) completed by \( \mathbb{P} \)-null sets. The space of control actions is a general metric space \( U \) endowed with its Borel \( \sigma \)-algebra \( \mathcal{B}(U) \). The class of admissible controls is defined as follows

\[
U := \{ u(\cdot) : \mathbb{R}_+ \times \Omega \to U : u(\cdot) \text{ is } (\mathcal{F}_t)_{t \geq 0} \text{ - progressive} \}.
\]

For \( r \in \mathbb{R}, \ p > 1 \) and a Banach space \( E \), we define

\[
L_{\mathbb{P}}^p(\mathbb{R}_+; E) : = \left\{ v(\cdot) : \mathbb{R}_+ \times \Omega \to E : v(\cdot) \text{ is } (\mathcal{F}_t)_{t \geq 0} \text{ - progressive} \right\}.
\]

We want to study an infinite horizon stochastic control problem in \( \mathbb{R}^n \) of the form

\[
\begin{cases}
\d X_t = b(X_t, u_t)dt + \sigma(X_t, u_t)dW_t, & \forall t \geq 0, \\
X_0 = x,
\end{cases}
\]

where \( x \in \mathbb{R} \) and \( u(\cdot) \) is an admissible control. The discounted functional to be minimized is given by

\[
J(u(\cdot)) = \mathbb{E} \int_0^{+\infty} e^{-r t} f(X_t, u_t)dt.
\]

By \( | \cdot | \) we denote the Euclidean norm on \( \mathbb{R}^n \), \( \| \cdot \| \) stands for a Frobenius norm on \( \mathbb{R}^{n \times d} \) and, finally, \( \| \cdot \|_2 \) denotes the Hilbert-Schmidt norm on \( \mathbb{R}^{n \times n} \). By \( \mathcal{S}^n \) we denote the set of symmetric matrixes \( \mathbb{R}^{n \times n}, \chi_A \) denotes the characteristic function of a set \( A \).

### Hypotheses:

(H1) \((U,d)\) is a separable metric space.
(H2) **(Polynomial growth)** The vector field \( b : \mathbb{R}^n \times U \to \mathbb{R}^n \) is \( B(\mathbb{R}^n) \otimes B(U) \)-measurable and the map \( x \mapsto b(x, u) \) is of class \( C^2 \). Moreover, there exists \( m \geq 0 \) such that

\[
\sup_{u \in U} \sup_{x \in \mathbb{R}^n} \frac{|D^\beta b(x, u)|}{1 + |x|^{2m+1}} < +\infty, \quad |eta| = 0, 1, 2.
\]  

(7)

(H3) **(Polynomial growth)** The mapping \( \sigma : \mathbb{R}^n \times U \to \mathbb{R}^{n \times d} \) is measurable with respect to \( B(\mathbb{R}^n) \otimes B(U) \). Moreover the map \( x \mapsto \sigma(t, x, u) \) is \( C^2(\mathbb{R}^n; \mathbb{R}^{n \times d}) \) and there exists \( m \) (same as in (H2)) such that

\[
\sup_{u \in U} \sup_{x \in \mathbb{R}^n} \frac{\|D^\beta \sigma(x, u)\|_2}{1 + |x|^m} < +\infty, \quad |eta| = 0, 1, 2.
\]  

(8)

(H4) **(Joint monotonicity)** Let \( p > 0 \). Then there exists \( c_p \in \mathbb{R} \) such that,

\[
\langle D_x b(x, y), y \rangle + p \|D_x \sigma(x, y)\| \leq c_p \|y\|^2, \quad x, y \in \mathbb{R}^n, u \in U.
\]  

(9)

(H5) **(Cost)** The function \( f : \mathbb{R}^n \times U \to \mathbb{R} \) is \( B(\mathbb{R}^n) \otimes B(U) \)-measurable and the map \( x \mapsto f(x, u) \) is of class \( C^2 \). Moreover, there exists \( l \geq 0 \) such that

\[
\sup_{u \in U} \sup_{x \in \mathbb{R}^n} \frac{|D^\beta f(x, u)|}{1 + |x|^l} < +\infty, \quad |eta| = 0, 1, 2.
\]  

(10)

Remark 1.

(a) In [3], the form of (H2) and (H3) is given in a stronger way. For our purposes the above formulation is sufficient.

(b) It is possible to show that condition (H2) implies that for any \( x, y \in \mathbb{R}^n \)

\[
\langle b(x, u) - b(y, u), x - y \rangle + p \|\sigma(x, u) - \sigma(y, u)\|^2 \leq c_p \|x - y\|^2, \quad u \in U.
\]  

(11)

and the two conditions are equivalent for coefficients twice differentiable (in \( x \)) which, in fact, is our case.

(c) The joint monotonicity condition (H4) also implies the so called coercivity condition (see i.e. [3], page 44). Indeed, let us fix \( y = 0 \), then (H4) reduces to

\[
\langle b(x, u) - b(0, u), x \rangle + p \|\sigma(x, u) - \sigma(0, u)\|^2 \leq c_p \|x\|^2,
\]  

(12)

and

\[
\|\sigma(x, u) - \sigma(0, u)\|^2 \geq \|\sigma(x, u)\|_2 - \|\sigma(0, u)\|_2
\]

\[
= \|\sigma(x, u)\|_2^2 + \|\sigma(0, u)\|_2^2 - 2\|\sigma(x, u)\|_2 \|\sigma(0, u)\|_2
\]

\[
\geq \|\sigma(x, u)\|_2^2 + \|\sigma(0, u)\|_2^2 - \|\sigma(x, u)\|_2^2 - \|\sigma(0, u)\|_2^2 - \frac{\|\sigma(x, u)\|_2^2}{\varepsilon}
\]

\[
= (1 - \varepsilon)\|\sigma(x, u)\|_2^2 + \|\sigma(0, u)\|_2^2 - \frac{\|\sigma(0, u)\|_2^2}{\varepsilon}, \quad \forall \varepsilon \in (0, 1).
\]

Then after easy computation we obtain that

\[
\langle b(x, u), x \rangle + p(1 - \varepsilon)\|\sigma(x, u)\|_2^2 \leq \hat{K}_p (1 + |x|^2), \quad \varepsilon \in (0, 1).
\]  

(13)

Let us note that \( |b(0, u)| + |\sigma(0, u)| \leq C \) due to the polynomial growth (H2)-(H3), hence \( \hat{K}_p \) can be chosen as \( \hat{K}_p = \max \{c_p + 1/2, C^2/2, 1\} \).

(d) The above Hypotheses (H2)-(H5) can be generalized to the situation of time dependent stochastic coefficients under natural assumptions without any influence on the main result.
3. Motivations and examples

Apart from the classical Lipschitz setting, there are two usual sets of assumptions which assure global existence and uniqueness of the solution to an SDE. The first one consists in local Lipschitz property of the coefficients along with the so called coercivity condition

\[ \langle b(x), x \rangle + \frac{1}{2} \| \sigma(x) \|^2 \leq K(1 + |x|^2), \]

for all \( x \in \mathbb{R}^n \) and some \( K \in \mathbb{R} \). The second set comprises some dissipativity assumptions on the drift, still with Lipschitz diffusion term. The dissipativity is expressed by

\[ \langle b(x) - b(y), x - y \rangle \leq K|x - y|^2, \]

for all \( x, y \in \mathbb{R}^n \) and some \( K \in \mathbb{R} \).

Another step further in this direction is the so called global monotonicity assumption, which is formulated as a joint condition for drift and diffusion

\[ \langle b(x) - b(y), x - y \rangle + \frac{1}{2} \| \sigma(x) - \sigma(y) \|^2 \leq c|x - y|^2, \]

for all \( x, y \in \mathbb{R}^n \). It is important to mention that the joint monotonicity property immediately implies the dissipativity of the drift but not necessarily global Lipschitzianity of the diffusion part. Moreover, the joint monotonicity \((15)\) also implies the coercivity property \((14)\).

It turns out that for the purposes of the SMP it is natural to strengthen the global monotonicity assumption in the following form: for all fixed \( p > 0 \) there exists \( c_p \in \mathbb{R} \) such that

\[ \langle b(x) - b(y), x - y \rangle + p \| \sigma(x) - \sigma(y) \|^2 \leq c_p|x - y|^2, \]

for all \( x, y \in \mathbb{R}^n \). This is motivated by the attempt to solve not only the state equation, but also the first and second variation equations and to derive some appropriate estimates of higher moments of the solutions. Another natural assumption in this framework is the polynomial growth of the coefficients along with their derivatives. This is fundamental in order to choose the correct discount factor in the definition of the weighted spaces \( L^{2, -p} (\mathbb{R}_+; \mathbb{R}^n) \) that we are going to use. Let us also mention that these polynomial bounds allow us to prove the local Lipschitzianity of the coefficients of the state equation.

To conclude, notice that the freedom in choosing \( p \) in the definition of \((16)\) implies the existence of a link between the growth of the diffusion term and the drift (compare \((H2)\) and \((H3)\), see also \[2\]). For example, to gain a quadratic growth in the diffusion we have to require the system to be more dissipative. Concretely, one such an example is

\[ dX_t = \left[ X_t - X_t^2 \right] dt + X_t^2 dW_t. \]

A more general framework is presented in \[13\] and \[8\] where the authors do not ask for polynomial growth of the coefficients and present a weak local version of the global monotonicity assumption along with a weak coercivity assumption. By weak we mean the presence of stochastic coefficients instead of constant ones in the definitions of the conditions, see \[19\] for a detailed exposure.

After this preliminary discussion we also present some concrete models.

(1) **Polynomial model:** As we have discussed above, a one dimensional model given by the SDE

\[ dX_t = \left[ -X_t^{2m+1} + \sum_{i=1}^{2m} a_i X_t^i \right] dt + \left[ \sum_{i=1}^{m} b_i X_t^i \right] dW_t; \quad X_0 = x \in \mathbb{R}, \]

for some \( a_i, b_i \in \mathbb{R} \), is the simplest example we have in mind. Let us notice that we can easily generalize the model in a way so that these polynomials are upper bounds for some more general (but locally Lipschitz) functions satisfying the joint monotonicity condition.

(2) **Population growth models:** A model in \( \mathbb{R} \) given by the SDE

\[ dX_t = \alpha X_t h(X_t) dt + \sigma X_t dW_t; \quad X_0 = x > 0, \]

where \( h(x) = 1 - \beta \ln(x) \), for so called Gompertz growth models (tumor growth models etc.) or \( h(x) = 1 - \beta x \), for so called logistic growth models (population dynamics models etc.). A detailed discussion of the controlled logistic model on infinite time horizon can...
be found [10]. In both cases, \( \alpha > 0 \) is the speed of growth and \( \beta > 0 \) represents some saturation level of the system. It can be shown by Lyapunov techniques that the solution is positive and an explicitly analytic formula can be found by linearizing the two equations. It is important to mention that our version of SMP covers the case of controlled logistic models (in full generality) whereas the controlled Gompertz model can be treated only with uncontrolled diffusion. This fact is due to the lack of polynomial growth condition needed in (H2) and the second variation equation might not be well posed. The same argument holds for another generalizations of the two population models with different choices of diffusion term (\( \sigma x(1 - \ln(x)), \sigma \sqrt{x(1 - \ln(x))}, \sigma \sqrt{x(1 - x)} \) etc.).

(3) **Gradient flow model with stochastic perturbation:** Let \( K \) be a convex open subset of \( \mathbb{R}^d \) and \( \varphi : K \subseteq \mathbb{R}^d \to \mathbb{R} \) a \( \lambda \)-convex function, i.e.

\[
\varphi((1 - \alpha)x_0 + \alpha x_1) \leq (1 - \alpha)\varphi(x_0) + \alpha \varphi(x_1) - \frac{\lambda}{2} \alpha(\alpha - 1)|x_1 - x_0|^2,
\]

for every \( x_0, x_1 \in \mathbb{R}^d \) and \( \alpha \in [0, 1] \). Then we can study a SDE of the form

\[
dX_t = -\nabla \varphi(X_t)dt + \sigma(X_t)dW_t,
\]

provided that \( \varphi \) is of class \( C^1 \). In fact, \( \lambda \)-convexity (with \( C^1 \)-regularity) is equivalent to

\[
\langle \nabla \varphi(y), y - x \rangle - \frac{\lambda}{2}|y - x|^2 \geq \varphi(y) - \varphi(x) \geq \langle \nabla \varphi(x), y - x \rangle + \frac{\lambda}{2}|y - x|^2
\]

which in particular implies that \( \nabla \varphi \) is \( \lambda \)-dissipative. If we ask \( \sigma \) to be Lipschitz, then [11] is satisfied.

Some possible choices of \( \varphi(\cdot) \) are:

- Take \( \lambda = 0 \) and \( \varphi(x) = |x|^{2k} \) convex with the derivative \( 2k|x|^{2k-2}x \);
- (Double-well potential) Let \( d = 1 \) and consider \( \varphi(x) = (x^2 - 1)^2 \), which is not convex (\( \pm 1 \) are minima) but \( \lambda \)-convex.
- Let \( d = 2 \) and consider the following dynamics

\[
\begin{aligned}
\dX_t &= -X_t dt + X_t Y_t^2(1 + X_t^2)^{-2}dt + \sigma dW^{(1)}_t, \\
\dY_t &= -Y_t(1 + X_t^2)^{-1}dt + \sigma dW^{(2)}_t.
\end{aligned}
\]

Here the energy has the following form \( \varphi = \varphi_1 + \varphi_2 \), where

\[
\varphi_1(x, y) = \frac{x^2}{2} \quad \text{and} \quad \varphi_2(x, y) = \frac{y^2}{2(1 + x^2)}.
\]

The difference between this case and the previous one is that here, the energy has not isolated minima but rather forms a sub-manifold (i.e. the \( x \)-axis).

4. **State equation**

In this section we provide the existence and uniqueness theorem for the state equation [3]. The classical proof of such theorem under our Hypotheses (H1)-(H4) goes along the lines as in [3], Section 1.2. for a solution in the space \( L^2_F([0, T]; \mathbb{R}^n) \) (thus not in exponentially weighted space \( L^{2-r}_F([0, T]; \mathbb{R}^n) \)). Nevertheless, by these arguments one can not obtain a contraction from \( L^{2-r}_F([0, +\infty); \mathbb{R}^n) \) to itself (not even locally in time). Hence an another approach has to be chosen. More specifically, we will scale the original equation in a way so that the classical result from [3] can be applied. We stress that, in this case, the bound for the discount factor depends on \( c_p \) which can be also negative.

**Theorem 1.** Let Hypotheses (H1)-(H4) hold. Then for every admissible control \( u(\cdot) \) there is a unique solution process \( (X_t)_{t \geq 0} \) to SDE (3) with \( \sup_{t \in [0, T]} \mathbb{E}[e^{-rt}|X_t|^2] < +\infty, \) for each \( T > 0 \) and for \( r > 2\alpha_1/2 \). Moreover, for all \( q \geq 2 \) and for \( r > 2\alpha_{q-1} \) it holds

\[
\mathbb{E} \int_0^\infty e^{-rt} |X_t|^{2q} dt \leq C_1|x|^{2q}, \quad \text{for some constant } C_1 = C_1(q) > 0,
\]
where \( c_{q-1} \) is the joint monotonicity constant in (9). In addition, for \( q \in \left( \frac{1}{2}, 2 \right) \) and \( r > 4c_1 \), it holds

\[
E \int_0^\infty e^{-rt}|X_t|^{2q} dt \leq C_2 |x|^4, \quad \text{for some constant } C_2 = C_2(q) > 0.
\] (19)

**Proof.** Without loss of generality we prove the result for uncontrolled case (which can be easily converted to the controlled one). The idea is to apply the result from [3] to a transformed equation which corresponds to our original equation. Assume for a moment that we already have a process \( \tilde{X} \) satisfying the dynamics given by (3) and define \( \tilde{X}_t \equiv e^{-\tilde{t}x}X_t \). Then \( \tilde{X} \) solves

\[
\begin{cases}
    d\tilde{X}_t = -\frac{r}{2} \tilde{X}_t + e^{-\tilde{t}^2b} \tilde{X}_t dt + e^{-\tilde{t}^2} \sigma \left( e^{\tilde{t}^2} \tilde{X}_t \right) dW_t, & \forall t \geq 0, \\
    \tilde{X}_0 = x.
\end{cases}
\] (20)

Denoting \( \tilde{b}(t, x) = -\frac{r}{2}x + e^{-\tilde{t}^2b}(e^{\tilde{t}^2}x) \) and \( \tilde{\sigma}(t, x) = e^{-\tilde{t}^2} \sigma(e^{\tilde{t}^2}x) \) it is easy to check that \( \tilde{b}, \tilde{\sigma} \) also satisfy assumptions (H1)-(H4). Differentiability and polynomial growth (H2)-(H3) are evident whereas joint monotonicity (H4) holds in the following sense

\[
\langle \tilde{b}(t, x) - \tilde{b}(t, y), x - y \rangle + p||\tilde{\sigma}(t, x) - \tilde{\sigma}(t, y)||^2 \leq \tilde{c}_p|x - y|^2, \quad \tilde{c}_p = c_p - \frac{r}{2}.
\] (21)

Hence, due to [3], Section 1.2 there exists a unique predictable process \( \tilde{X} \) solving (20) which satisfies

\[
\sup_{t \in [0,T]} E|\tilde{X}_t|^2 < +\infty, \quad \forall T > 0.
\] (22)

The last step is proving the desired exponentially weighted integrability. Denote the exit time \( \tau_K := \inf \{ t \geq 0 : |\tilde{X}_t| \geq K \} \) for each \( K > 0 \) with the usual convention \( \inf \{ 0 \} := +\infty \). It is easy to show that \( \tau_K \not\to +\infty, \) for \( K \to +\infty \) a.s.

Proof of estimate (13): Let us fix \( q \geq 2 \) and apply the Itô formula to \( |\tilde{X}_{t\wedge \tau_K}|^{2q} \). We also denote \( \tilde{\alpha}_s = \tilde{\sigma}(s, \tilde{X}_s) \tilde{\sigma}(s, \tilde{X}_s)^T \). Then we obtain

\[
E|\tilde{X}_{t\wedge \tau_K}|^{2q} = |x|^{2q} + 2qE \int_0^t \chi_{\{\tau_K \geq s\}} |\tilde{X}_s|^{2(q-1)} \left( \langle \tilde{X}_s, \tilde{b}(s, \tilde{X}_s) \rangle + \frac{1}{2} Tr \{ \tilde{\alpha}_s \} \right) ds \]

\[
+ 2q(q-1)E \int_0^t \chi_{\{\tau_K \geq s\}} |\tilde{X}_s|^{2(q-2)} Tr \{ \tilde{\alpha}_s \langle \tilde{X}_s \otimes \tilde{X}_s \rangle \} ds \]

\[
\leq |x|^{2q} + 2q\tilde{K}_{q-1}^2 \tilde{c}_{q-1} E \int_0^t \chi_{\{\tau_K \geq s\}} \left( |\tilde{X}_s|^{2q} + 1 \right) ds \]

\[
= |x|^{2q} + 2q\tilde{K}_{q-1} \tilde{c}_{q-1} (t \wedge \tau_K) + 2q\tilde{K}_{q-1} \tilde{c}_{q-1} \int_0^t E|\tilde{X}_{s\wedge \tau_K}|^{2q} ds,
\] (23)

where we have used the joint monotonicity in the form of (11) and coercivity-type estimate (13).

By Gronwall lemma it easily follows that

\[
E|\tilde{X}_{t\wedge \tau_K}|^{2q} \leq \left( |x|^{2q} + 2q\tilde{K}_{q-1} \tilde{c}_{q-1} (t \wedge \tau_K) \right) e^{2q\tilde{K}_{q-1} \tilde{c}_{q-1} (t \wedge \tau_K)} \leq |x|^{2q} e^{2q\tilde{K}_{q-1} (\tilde{c}_{q-1} - \frac{r}{2}) t}.
\]

The last estimate can be made for \( r \geq 2c_{q-1} \). Consequently, the final estimate reads

\[
E|\tilde{X}_t|^{2q} \leq |x|^{2q} e^{2q\tilde{K}_{q-1} (\tilde{c}_{q-1} - \frac{r}{2}) t},
\]

and it follows by Fatou. Expressed in terms of the process \( X \) we have that for all \( t \geq 0 \) it holds

\[
E \left[ e^{-rt} |X_t|^{2q} \right] \leq |x|^{2q} e^{2q\tilde{K}_{q-1} (\tilde{c}_{q-1} - \frac{r}{2}) t}.
\] (24)

Now it is sufficient to integrate both sides of (24) on \([0, +\infty)\).
Proof of estimate (19): Fix $q \geq 2$ and observe that $e^{-rt} |X^q_t| = e^{r(t-q)} |\tilde{X}^q_t|$. Therefore, applying Itô formula to $e^{r(t-q)} |\tilde{X}^q_t|$ gives
\[
\mathbb{E} \left[ e^{r(t-q)(t \wedge \tau_K)} |\tilde{X}^q_{t \wedge \tau_K}|^2 \right] = |x|^2 + 2q \mathbb{E} \int_0^t \chi_{\tau_K \geq s} e^{r(q-1)s} |\tilde{X}^q_s|^2 (q-1) \times \\
\times \left( \tilde{X}_s, \tilde{b}(s, \tilde{X}_s) \right) + \frac{1}{2} \text{Tr} \left\{ \tilde{\sigma}_s \right\} ds \\
+ 2q(q-1) \mathbb{E} \int_0^t \chi_{\tau_K \geq s} e^{r(q-1)s} |\tilde{X}^q_s|^2 ds \\
+ \left( 2q \tilde{K}_{q-1} \tilde{c}_{q-1} + r(q-1) \right) \mathbb{E} \int_0^t e^{r(q-1)(t \wedge \tau_K)} |\tilde{X}^q_{t \wedge \tau_K}|^2 ds.
\]
Then, similarly as before, we obtain
\[
\mathbb{E} \int_0^\infty e^{-rt} |X^q_t|^2 dt \leq C_2 |x|^2, \text{ for } r > 2q \tilde{K}_{q-1} \tilde{c}_{q-1}, \tag{25}
\]
To conclude the proof observe that once we have obtained the estimates (25) for $q \geq 2$, the case $q \in [1/2, 2)$ easily follows by Hölder inequality. Note that we have proved even more than stated in the assertion of the theorem. Nevertheless, such generality is not needed for the purposes of proving the SMP. \hfill \Box

5. Spike variation and variation equations

The derivation of the variational inequality needed for the formulation of SMP is based on expanding the difference of the functional $J(u^\varepsilon(\cdot)) - J(\tilde{u}(\cdot))$ where $\tilde{u}(\cdot)$ is an optimal control and $u^\varepsilon(\cdot)$ is its appropriate perturbation. Since the control variable is allowed to enter also the diffusion term, the expansion has to be carried out up to second order due to the time irregularity of the noise. Therefore, two forward variation equations appear in our setting: first order variation process $y^\varepsilon$ being, in fact, a linearization of the state process, and the second order variation process $z^\varepsilon$ coming from the second order expansion. We also stress that due to the estimation techniques used in the forthcoming proofs, we often need the polynomial bound of coefficients to be integrable with the weight, which immediately implies that $r$ has to be a priori positive.

Let $\varepsilon > 0$, $E_\varepsilon \subset \mathbb{R}_+$ be a set of measure $\varepsilon$ of the form $E_\varepsilon := [t_0, t_0 + \varepsilon]$, with $t_0 \geq 0$ arbitrary but fixed, and $\tilde{u}(\cdot)$ an optimal control. Define the spike variation $u^\varepsilon(\cdot)$ of $\tilde{u}(\cdot)$ by the formula
\[
u^\varepsilon_t = \begin{cases} 
\tilde{u}_t, & \text{if } t \in \mathbb{R}_+ \setminus E_\varepsilon, \\
v_t, & \text{if } t \in E_\varepsilon,
\end{cases}
\]
where $v \in U$ is an arbitrary and fixed point.

Let $(\tilde{X}(\cdot), \tilde{u}(\cdot))$ be a given optimal pair and $(X^\varepsilon(\cdot), u^\varepsilon(\cdot))$ satisfy the following perturbed SDE
\[
\begin{cases}
\,dX^\varepsilon_t = b(X^\varepsilon_t, u^\varepsilon_t) dt + \sigma(X^\varepsilon_t, u^\varepsilon_t) dW_t, \\
\,X^\varepsilon_0 = x.
\end{cases}
\tag{26}
\]
Further, following the notation of Yong and Zhou [24], we denote by $\delta \varphi$, the quantity $\varphi(\tilde{X}_t, \tilde{u}_t) - \varphi(\tilde{X}_t, \tilde{u}_t)$, for a generic function $\varphi$.

Now, let us begin studying the first variation equation
\[
\begin{cases}
\,dy^\varepsilon_t = D_x \tilde{b}(\tilde{X}_t, \tilde{u}_t) y^\varepsilon_t dt + \sum_{j=1}^d \left[ D_{y^\varepsilon_j} \tilde{b}(\tilde{X}_t, \tilde{u}_t) y^\varepsilon_t + \delta \sigma^j_t \right] dW^j_t, \\
\,y^\varepsilon_0 = 0,
\end{cases}
\tag{27}
\]
and the second variation equation...
Then it holds
\[
\begin{aligned}
\begin{cases}
   dz_1^t &= \left[ D_x b(X_t, \bar{u}_t)z_1^t + \delta b_t \chi_{E_0}(t) + \frac{1}{2} D_{x}^2 b(X_t, \bar{u}_t)(y_1^t)^2 \right] dt \\
   + \sum_{j=1}^{d} D_x \sigma^j(X_t, \bar{u}_t)z_j^t + \delta (D_x \sigma^j_1)(y_1^t) \chi_{E_0}(t) + \frac{1}{2} D_{x}^2 \sigma^j(X_t, \bar{u}_t)(y_j^t)^2 \right] dW_j^t, \\
   z_0^t &= 0,
\end{cases}
\end{aligned}
\]
where we have adopted the notation
\[
D_x^2 b(X_t, \bar{u}_t)(y_1^t)^2 := \begin{pmatrix}
   \text{Tr}[D_x^2 b^1(X_t, \bar{u}_t)y_1^t(y_1^t)^T] \\
   \vdots \\
   \text{Tr}[D_x^2 b^n(X_t, \bar{u}_t)y_1^t(y_1^t)^T]
\end{pmatrix},
\]
\[
D_x^2 \sigma^j(X_t, \bar{u}_t)(y_j^t)^2 := \begin{pmatrix}
   \text{Tr}[D_x^2 \sigma^{ij}(X_t, \bar{u}_t)y_j^t(y_j^t)^T] \\
   \vdots \\
   \text{Tr}[D_x^2 \sigma^{nj}(X_t, \bar{u}_t)y_j^t(y_j^t)^T]
\end{pmatrix}.
\]

**Theorem 2.** Let Hypotheses (H1)-(H4) hold. Then there exist \( r_1 \in \mathbb{R}, \ r_2 > 0 \) such that equation (27) (equation (28), resp.) admits a unique solution \( y^\varepsilon \in L^2_{2^{-r_1}}(\mathbb{R}_+: \mathbb{R}^n) \) \((z^\varepsilon \in L^2_{2^{-r_2}}(\mathbb{R}_+: \mathbb{R}^n), \) resp.) for all admissible controls \( u(\cdot) \in U \).

**Proof.** Note first that (27) and (28) are linear equations in \( y^\varepsilon \) and \( z^\varepsilon \), respectively. The perturbation of the diffusion in (27) belongs to \( L^2_{2^{-r}}(\mathbb{R}_+: \mathbb{R}^n) \) for every \( r \), and it is independent on \( y^\varepsilon \). Therefore, the joint monotonicity condition (11) holds and the proof follows by similar arguments as the proof of Theorem 1 for \( r_1 > 2c_1, 2 \). Concerning the equation for \( z^\varepsilon \), we have to choose \( r_2 \) such that \( D_x^2 b(X_t, \bar{u}_t)(y_1^t)^2, D_x^2 \sigma^j(X_t, \bar{u}_t)(y_j^t)^2 \in L^2_{2^{-r_2}}(\mathbb{R}_+: \mathbb{R}^n) \). Then existence and uniqueness of a solution follow. \( \square \)

**Remark 2.** Let us note that, thanks to the linearity of the equation and due to the structure of the forcing term \( \delta \sigma^j \), the solution \( y^\varepsilon \) to the equation (27) is identically zero for times \( t \leq t_0 \).

In the rest of this section, we will often benefit from a general estimate of the solution to a linearized SDE given by the following Lemma.

**Lemma 1.** Let \( Y \in L^2_{2^{-r}}(\mathbb{R}_+: \mathbb{R}^n) \) be a solution to the following linear SDE
\[
\int dY_t = (A_1 Y_t + \alpha_t) dt + \sum_{j=1}^{d} (B_j Y_t + \beta_j) dW_t^j,
\]
where \( y_0 \in \mathbb{R}^n; \ A, B^j : \mathbb{R}_+ \times \Omega \rightarrow \mathbb{R}^{n \times n} \), \( \alpha, \beta^j : \mathbb{R}_+ \times \Omega \rightarrow \mathbb{R}^n \), \( j = 1, \ldots, d \), all are \((\mathcal{F}_t)-\)progressively measurable processes. Let \( k \geq 1, \ p > 0 \) and \( c_p \in \mathbb{R} \) such that

1. \( \langle A_1 Y_t, Y_t \rangle + p \sum_{j=1}^{d} |B_j Y_t|^2 \leq c_p |Y_t|^2, \ \mathbb{P} \otimes dt \text{-a.e.} \)
2. \( \int_0^\infty e^{-r t} (\mathbb{E} |\alpha_t|^{2k})^{\frac{1}{2k}} + e^{-rt} \left( \mathbb{E} \left( \sum_{j=1}^{d} |\beta_j^j|^{2k} \right)^{\frac{1}{2}} \right) dt < +\infty, \ \ 1 \leq j \leq d, \text{ and } r > 2c_{2k-1}. \)

Then it holds
\[
\sup_{t \in \mathbb{R}_+} e^{-rkt} |Y_t|^{2k} \leq K \left[ |y_0|^{2k} + \left( \int_0^\infty e^{-\frac{rt}{2}} (\mathbb{E} |\alpha_t|^{2k})^{\frac{1}{2}} dt \right)^{2k} + \left( \int_0^\infty e^{-rt} \left( \mathbb{E} \left( \sum_{j=1}^{d} |\beta_j^j|^{2k} \right)^{\frac{1}{2}} \right) dt \right)^{k} \right],
\]
where \( K = K(\delta) \), for some appropriate \( \delta > 0 \) and \( r > 2c_{2k-1}. \)

**Proof.** The proof will be given for all \( B^j, \beta^j \)’s bounded. Then the stochastic integral in the proof is a true (centered) martingale. The proof for the unbounded case follows immediately by standard localization and the Fatou lemma.
Let $2k, k \geq 2$ and apply the Itô formula to $e^{-rt}|Y_t|^{2k}$ on $[0, t]$. The case $k \in \{1/2, 2\}$ follows easily by the Hölder inequality.

\[
\mathbb{E}(e^{-rkt}|Y_t|^{2k}) = \mathbb{E}|y_0|^{2k} + 2kE \int_0^t e^{-rks}|Y_s|^{2k-2} \langle A_s Y_s + \alpha_s, Y_s \rangle ds \\
+ 2k(k - 1) \sum_{j=1}^d E \int_0^t e^{-rks}|Y_s|^{2k-4} \langle B_s^j Y_s + \beta_s^j, Y_s \rangle^2 ds \\
+ k \sum_{j=1}^d E \int_0^t e^{-rks}|Y_s|^{2k-2} \langle B_s^j Y_s + \beta_s^j, B_s^j Y_s + \beta_s^j \rangle ds \\
- r k \mathbb{E} \int_0^t e^{-rks}|Y_s|^{2k} ds \\
\leq \mathbb{E}|y_0|^{2k} + 2kE \int_0^t e^{-rks}|Y_s|^{2k-2} \langle A_s Y_s, Y_s \rangle + (2k - 1) \sum_{j=1}^d |B_s^j Y_s|^2 \rangle ds \\
- r k \mathbb{E} \int_0^t e^{-rks}|Y_s|^{2k} ds.
\]

(30)

Now, using Hölder and the weighted Young inequality $ab \leq \frac{a^p b^q}{p} + \frac{b^r}{q^r}$, $a, b \geq 0, \delta > 0$, the remaining terms can be treated as follows

\[
2k \mathbb{E} \int_0^t e^{-rks}|Y_s|^{2k-1}|\alpha_s| ds \leq 2k \left( \sup_{t \in \mathbb{R}^+} e^{-rkt} \mathbb{E} \left( |Y_t|^{2k-1} \right) \right)^{\frac{1}{2k-1}} \int_0^\infty e^{-\frac{r}{2k}t} \left( \mathbb{E}\left| \alpha_t \right|^{2k} \right)^{\frac{1}{2k}} dt \\
\leq (2k - 1) \delta^{\frac{1}{2k}} \left( \sup_{t \in \mathbb{R}^+} e^{-rkt} \mathbb{E}|Y_t|^{2k} \right) + \frac{1}{\delta^{2k}} \left( \int_0^\infty e^{-\frac{r}{2k}t} \left( \mathbb{E}\left| \alpha_t \right|^{2k} \right)^{\frac{1}{2k}} dt \right)^{\frac{1}{2k}},
\]

(31)

and similarly

\[
2k(2k - 1) \mathbb{E} \int_0^t e^{-rks}|Y_s|^{2k-2} \left( \sum_{j=1}^d |\beta_s^j|^2 \right) ds \leq 2k(2k - 1) \delta^{\frac{1}{2k-1}} \left( \sup_{t \in \mathbb{R}^+} e^{-rkt} \mathbb{E}|Y_t|^{2k} \right) \\
+ 2(2k - 1) \frac{1}{\delta^{2k}} \left( \int_0^\infty e^{-rt} \left( \mathbb{E}\left| \sum_{j=1}^d |\beta_t^j|^{2k} \right|^{\frac{1}{2k}} \right)^{\frac{1}{2k}} dt \right) \left( \frac{1}{2k-1} \right)^k.
\]

(32)

The estimate (23) easily follows by substituting (31) and (32) into (30), by taking $sup_{t>0}$ on both sides and finally by choosing $\delta > 0$ such that $1 - (2k - 1) \delta^{\frac{2k}{2k-1}} - 2(k - 1)(2k - 1) \delta^{\frac{2k}{2k-1}} > 0$ and $r > 2c_{2k-1}$.

Before proceeding, let us recall that by $\bar{X}$ and $X^\varepsilon$ we mean the solution to (5) in the space $L^{2-\tau}_T(\mathbb{R}^+; \mathbb{R}^n)$, for $r > 2c_{1/2}$, corresponding to $u(\cdot)$ and $u^\varepsilon(\cdot)$, respectively. $y^\varepsilon$ and $z^\varepsilon$ are the solutions to (27) and (28), respectively.

**Proposition 1.** Suppose Hypotheses (H1)-(H4) hold and $r > 2c_{1/2}$. Define $\xi^\varepsilon := X^\varepsilon - \bar{X}_t$, $\eta^\varepsilon := \xi^\varepsilon - \bar{Y}_t$ and $\zeta^\varepsilon := \xi^\varepsilon - \bar{y}^\varepsilon - \bar{z}^\varepsilon$, $t \geq 0$. Then there exist $\rho_1, \ldots, \rho_5 > 0$ such that for $k = 1, 2, \ldots$ it holds

(i) $\sup_{t \in \mathbb{R}^+} e^{-\rho_1kt}\mathbb{E}|\xi^\varepsilon|^2k = O(\varepsilon^k)$,
(ii) $\sup_{t \in \mathbb{R}^+} e^{-\rho_2kt}\mathbb{E}|\eta^\varepsilon|^2k = O(\varepsilon^k)$,
(iii) $\sup_{t \in \mathbb{R}^+} e^{-\rho_3kt}\mathbb{E}|\zeta^\varepsilon|^2k = O(\varepsilon^k)$,
(iv) $\sup_{t \in \mathbb{R}^+} e^{-\rho_4kt}\mathbb{E}|\bar{y}^\varepsilon|^2k = O(\varepsilon^k)$,
(v) $\sup_{t \in \mathbb{R}^+} e^{-\rho_5kt}\mathbb{E}|\bar{z}^\varepsilon|^2k = O(\varepsilon^k)$.
Finally, Proposition 1 gives existence and uniqueness result can be derived for processes being in some exponentially-weighted the BSDE is solved on infinite time horizon and the behaviour at infinity is not known. Yet the some sense, the first adjoint process is dual to the linearized state equation (27) and it can have the be obtained by differentiating the Hamiltonian function with respect to the state variable □

Proof of Proposition 2. The following expansion holds for the cost functional

\[ J(u^ε(\cdot)) - J(\bar{u}(\cdot)) = \mathbb{E} \int_0^\infty e^{-rt} \left( D_x f(\bar{X}_t, \bar{u}_t), y^\varepsilon_t + z^\varepsilon_t \right) dt + \mathbb{E} \int_0^\infty e^{-rt} \left[ \frac{1}{2} \left( D^2_x f(\bar{X}_t, \bar{u}_t) y^\varepsilon_t, y^\varepsilon_t \right) + \delta f(\bar{X}_t, \bar{u}_t) \right] dt + o(\varepsilon), \]

where the discount factor \( r \geq \max_{i=1,...,5} \{ \rho_i \} \) and \( \rho_i \) are the individual discount factors from Proposition □

Proof of Proposition □ Thanks to Lemma 2, we have

\[ J(u^ε(\cdot)) - J(\bar{u}(\cdot)) = \mathbb{E} \int_0^\infty e^{-rt} \left[ f(\bar{X}_t, \bar{u}_t) - f(\bar{X}_t, \bar{u}_t) \right] dt = \mathbb{E} \int_0^\infty e^{-rt} \left[ \delta f(\bar{X}_t, \bar{u}_t) + \left( D_x f(\bar{X}_t, \bar{u}_t), \xi^\varepsilon_t \right) \right] dt + \mathbb{E} \int_0^\infty e^{-rt} \int_0^1 \left( \theta D^2_x f(\theta \bar{X}_t + (1 - \theta) X^\varepsilon_t, \bar{u}_t) \right) \xi^\varepsilon_t, \xi^\varepsilon_t \right) d\theta dt. \]

Finally, Proposition □ gives

\[ J(u^ε(\cdot)) - J(\bar{u}(\cdot)) = \mathbb{E} \int_0^\infty e^{-rt} \left[ \delta f(\bar{X}_t, \bar{u}_t) + \left( D_x f(\bar{X}_t, \bar{u}_t), \xi^\varepsilon_t \right) \right. \]
\[ + \left. \left( D_x f(\bar{X}_t, \bar{u}_t), y^\varepsilon_t + z^\varepsilon_t \right) + \left( D_x f(\bar{X}_t, \bar{u}_t), z^\varepsilon_t \right) \right] dt \]
\[ + \int_0^1 \left( \theta D^2_x f(\theta \bar{X}_t + (1 - \theta) X^\varepsilon_t, \bar{u}_t) \right) \xi^\varepsilon_t, \xi^\varepsilon_t \right) d\theta \]
\[ + \frac{1}{2} \left( \delta D^2_x f(\bar{X}_t, \bar{u}_t) \xi^\varepsilon_t, \xi^\varepsilon_t \right) + \frac{1}{2} \left( D^2_x f(\bar{X}_t, \bar{u}_t) y^\varepsilon_t, y^\varepsilon_t \right) \]
\[ + \frac{1}{2} \left( D^2_x f(\bar{X}_t, \bar{u}_t) y^\varepsilon_t, \xi^\varepsilon_t \right) + \frac{1}{2} \left( D^2_x f(\bar{X}_t, \bar{u}_t) \right) dt \]

\[ \mathbb{E} \int_0^\infty e^{-rt} \left( D_x f(\bar{X}_t, \bar{u}_t), y^\varepsilon_t + z^\varepsilon_t \right) dt \]
\[ + \mathbb{E} \int_0^\infty e^{-rt} \left[ \frac{1}{2} \left( D^2_x f(\bar{X}_t, \bar{u}_t) y^\varepsilon_t, y^\varepsilon_t \right) + \delta f(\bar{X}_t, \bar{u}_t) \right] dt + o(\varepsilon), \]

which completes the proof. □

6. First Adjoint Equation

The first adjoint process naturally arises as a solution to an appropriate BSDE whose driver can be obtained by differentiating the Hamiltonian function with respect to the state variable \( x \). In some sense, the first adjoint process is dual to the linearized state equation (27) and it can have the interpretation of generalized (in the sense of time-dependent and stochastic) Lagrange multipliers. In the classical setting for BSDEs, the terminal condition is given a priori. On the contrary, here the BSDE is solved on infinite time horizon and the behaviour at infinity is not known. Yet the existence and uniqueness result can be derived for processes being in some exponentially-weighted \( L^2 \) space.

In our case, the first order adjoint equation on infinite time horizon has the following form

\[ dp_t = -\left[ D_x b(\bar{X}_t, \bar{u}_t) p_t + D_x \sigma(\bar{X}_t, \bar{u}_t) q_t - D_x f(\bar{X}_t, \bar{u}_t) - r p_t \right] dt + q_t dW_t, \]
where $D_x \sigma(X_t, \tilde{u}_t)^T q_t := \sum_{j=1}^d D_x \sigma^j(X_t, \tilde{u}_t)^T q_t^j \in \mathbb{R}^n$ and $(X_t, \tilde{u}_t)$ is an optimal pair.

Let us start the analysis by proving an a priori estimate for the difference of solutions to (35). To do so, the following estimate will be of a particular interest since it allows to transfer the joint monotonicity property to the BSDE

$$\langle D_x \sigma(X_t, \tilde{u}_t)^T q_t, p_t \rangle = \sum_{j=1}^d \langle D_x \sigma^j(X_t, \tilde{u}_t)^T q_t^j, p_t \rangle = \sum_{j=1}^d \langle q_t^j, D_x \sigma^j(X_t, \tilde{u}_t) p_t \rangle$$

$$\leq \frac{1}{2} \sum_{j=1}^d |q_t^j|^2 + \frac{1}{2} \sum_{j=1}^d |D_x \sigma^j(X_t, \tilde{u}_t) p_t|^2 \leq \frac{1}{2} |q_t|^2 + \frac{1}{2} |D_x \sigma(X_t, \tilde{u}_t) p_t|^2.$$  \hspace{1cm} (36)

**Lemma 3.** Let $(p^1, q^1)$ and $(p^2, q^2)$ be two solutions to BSDE (35) belonging to the space $L^p_2([-\tau, t]; \mathbb{R}^n \times \mathbb{R}^{n \times d})$, for $r > 2c_1/2$, corresponding to $f = f^1$ and $f = f^2$. Then the following estimate holds true

$$\mathbb{E} \int_0^\infty e^{-rt} \left( |p^1_t - p^2_t|^2 + \frac{1}{2} |q^1_t - q^2_t|^2 \right) dt \leq \frac{1}{\delta} \mathbb{E} \int_0^\infty e^{-rt} |D_x f^1(X_t, \tilde{u}_t) - D_x f^2(X_t, \tilde{u}_t)|^2 dt,$$

where $\delta > 0$ is sufficiently small.

**Proof.** Applying Itô formula to $e^{-rt} |p^1_t - p^2_t|^2$ gives

$$|p^1_t - p^2_t|^2 + \mathbb{E} \int_0^\infty e^{-rt} \left( -r |p^1_t - p^2_t|^2 + |q^1_t - q^2_t|^2 \right) dt$$

$$= \mathbb{E} \int_0^\infty 2e^{-rt} \langle p^1_t - p^2_t, D_x b(X_t, \tilde{u}_t)^T (p^1_t - p^2_t) + D_x \sigma(X_t, \tilde{u}_t)^T (q^1_t - q^2_t) \rangle dt$$

$$+ \mathbb{E} \int_0^\infty 2e^{-rt} \langle p^1_t - p^2_t, -r(p^1_t - p^2_t) + D_x f^1(X_t, \tilde{u}_t) - D_x f^2(X_t, \tilde{u}_t) \rangle dt$$

$$\leq \mathbb{E} \int_0^\infty 2e^{-rt} \left( |p^1_t - p^2_t|^2 + \frac{1}{2} |D_x \sigma(X_t, \tilde{u}_t) (p^1_t - p^2_t)|^2 \right) dt$$

$$+ \mathbb{E} \int_0^\infty 2e^{-rt} \left( \frac{1}{2} |q^1_t - q^2_t|^2 + r |p^1_t - p^2_t|^2 \right) dt$$

$$+ \mathbb{E} \int_0^\infty 2e^{-rt} \left( \frac{\delta}{2} |p^1_t - p^2_t|^2 + \frac{1}{2\delta} |D_x f^1(X_t, \tilde{u}_t) - D_x f^2(X_t, \tilde{u}_t)|^2 \right) dt$$

$$\leq \mathbb{E} \int_0^\infty e^{-rt} \left( (2c_1/2 - 2r + \delta) |p^1_t - p^2_t|^2 + \frac{1}{2} |q^1_t - q^2_t|^2 \right) dt$$

$$+ \mathbb{E} \int_0^\infty e^{-rt} \frac{1}{\delta} |D_x f^1(X_t, \tilde{u}_t) - D_x f^2(X_t, \tilde{u}_t)|^2 dt,$$

where we have used the estimate (34), joint monotonicity assumption (H4) and weighted Young inequality. The conclusion easily follows. \hfill \Box

Before giving the proof of existence and uniqueness for the first adjoint equation we produce a preliminary result in finite time horizon $T > 0$. Let us consider the following equation:

$$dp_t = - \left[ D_x b(X_t, \tilde{u}_t)^T p_t + D_x \sigma(X_t, \tilde{u}_t)^T q_t - D_x f(X_t, \tilde{u}_t) - rp_t \right] dt + q_t dW_t,$$

$$p_T = 0,$$

where $T > 0$ is arbitrary but fixed.

As far as we know, no results in the literature can be used to solve this equation due to the polynomial growth of $D_x \sigma(X_t, \tilde{u}_t)^T$ in front of $q_t$. In order to produce existence of a solution to such equation we exploit some duality arguments.

**Theorem 3.** Under Hypotheses (H1)-(H5) equation (37) admits a unique solution $(p, q)$ which belongs to $L^2_2([0, T]; \mathbb{R}^n) \times L^p_2([0, T]; \mathbb{R}^{n \times d})$, for each $T > 0$. 

Solution to the limit equation

Due to Theorem 2 we know that the above equation has a unique solution in $\mathbb{R}^n$ so that the joint monotonicity property still holds. An example of such approximation can be given by (see [3])

$$\sigma^n(x) = \begin{cases} \sigma(x), & \text{if } |x| \leq n, \\ \sigma \left( \frac{(n+1)x}{|x|} \right), & \text{if } |x| \geq n + 1. \end{cases}$$

Then, for each $n$, the following approximating equation

$$\begin{cases} dp^n = -\left[ D_x b(\bar{X}_t, \bar{u}_t)^T p^n_t + D_x \sigma^n(\bar{X}_t, \bar{u}_t)^T q^n_t - D_x f(\bar{X}_t, \bar{u}_t) - rp^n_t \right]dt + q^n_t dW_t, \\ p^n_T = 0, \end{cases}$$

admits a unique solution $(p^n_t, q^n_t) \in L^2_\mathbb{F}([0, T]; \mathbb{R}^n) \times L^2_\mathbb{F}([0, T]; \mathbb{R}^{n \times d})$ thanks to Briand et al. [2], Theorem 4.1.

Now, to establish the duality, consider for all $\gamma(\cdot) \in L^2_\mathbb{F}([0, T]; \mathbb{R}^n)$ and $\eta(\cdot) \in L^2_\mathbb{F}([0, T]; \mathbb{R}^{n \times d})$ the following perturbed first variation equation

$$\begin{cases} dy^n_t = (D_x b(\bar{X}_t, \bar{u}_t)y^n_t - r y^n_t + \gamma_t) dt + (D_x \sigma^n(\bar{X}_t, \bar{u}_t)y^n_t + \eta_t) dW_t, & t \in (0, T), \\ y^n_0 = 0. \end{cases}$$

Due to Theorem 2 we know that the above equation has a unique solution in $L^2_\mathbb{F}([0, T]; \mathbb{R}^n)$ for each $n$. Moreover, using dissipativity it is easy to show that there exists $K > 0$ not depending on $n$ such that

$$\mathbb{E} \int_0^T |y^n_t|^2 dt \leq K \left[ \mathbb{E} \int_0^T |\gamma_t|^2 dt + \mathbb{E} \int_0^T ||\eta_t||^2 dt \right].$$

Next, by applying the Itô formula to $d \langle y^n_t, p^n_t \rangle$ we establish the duality relation

$$\mathbb{E} \int_0^T \langle p^n_t, \gamma_t \rangle dt + \mathbb{E} \int_0^T \text{Tr} \left\{ q^n_t (\eta_t)^T \right\} dt = -\mathbb{E} \int_0^T \langle D_x f(\bar{X}_t, \bar{u}_t), y^n_t \rangle dt.$$  

Let us define the set $A := \{ \gamma(\cdot) \in L^2_\mathbb{F}([0, T]; \mathbb{R}^n) : ||\gamma||_{L^2_\mathbb{F}([0, T]; \mathbb{R}^n)} \leq 1 \}$. If we take $\eta \equiv 0$ in (41) we get

$$\left( \mathbb{E} \int_0^T |p^n_t|^2 dt \right)^{1/2} \leq \sup_{\gamma \in A} \left[ \mathbb{E} \int_0^T \left| \langle D_x f(\bar{X}_t, \bar{u}_t), y^n_t \rangle \right| dt \right]$$

$$\leq \sup_{\gamma \in A} \left[ \left( \mathbb{E} \int_0^T |D_x f(\bar{X}_t, \bar{u}_t)|^2 dt \right)^{1/2} \left( \mathbb{E} \int_0^T |y^n_t|^2 dt \right)^{1/2} \right]$$

$$\leq C \left( \mathbb{E} \int_0^T |D_x f(\bar{X}_t, \bar{u}_t)|^2 dt \right)^{1/2}. \quad (42)$$

If we repeat the same argument with $\gamma \equiv 0$, instead of $\eta$, we finally get

$$||p^n_t||^2_{L^2_\mathbb{F}([0, T]; \mathbb{R}^n)} + ||q^n_t||^2_{L^2_\mathbb{F}([0, T]; \mathbb{R}^{n \times d})} \leq C \mathbb{E} \int_0^T |D_x f(\bar{X}_t, \bar{u}_t)|^2 dt.$$  

This way we have obtained a uniform estimate (with respect to $n$) of the $L^2_\mathbb{F}$-norm of $(p^n, q^n)$. Hence there exists a subsequence, denoted by abuse of notation again as $(p^n, q^n)$, which converges weakly in $L^2_\mathbb{F}([0, T]; \mathbb{R}^n) \times L^2_\mathbb{F}([0, T]; \mathbb{R}^{n \times d})$ to a couple $(p, q)$. Our goal is to verify that $(p, q)$ is the solution to the limit equation

$$\begin{cases} dp_t = -\left[ D_x b(\bar{X}_t, \bar{u}_t)^T p_t + D_x \sigma(\bar{X}_t, \bar{u}_t)^T q_t - D_x f(\bar{X}_t, \bar{u}_t) - rp_t \right] dt + q_t dW_t, \\ p_T = 0. \end{cases}$$
To do so, we note that due to the linearity of the equation, it is enough to prove that each term of the approximating equation weakly converges to the corresponding term in the limit equation. Let us start by studying the term

\[
\langle D_x \sigma^n(\bar{x}_t, \bar{u}_t)^T q^n_t, v \rangle = \langle q^n_t, D_x \sigma^n(\bar{x}_t, \bar{u}_t)v \rangle = \langle q^n_t, D_x \sigma(\bar{x}_t, \bar{u}_t)v \rangle + \langle q^n_t, D_x \sigma^n(\bar{x}_t, \bar{u}_t)v - D_x \sigma^n(\bar{x}_t, \bar{u}_t)v \rangle.
\]

As \(n \to \infty\), the right hand side converges to

\[
\langle q_t, D_x \sigma(\bar{x}_t, \bar{u}_t)v \rangle = \langle D_x \sigma(\bar{x}_t, \bar{u}_t)^T q_t, v \rangle,
\]
	hanks{2}

thanks to the pointwise convergence of the derivative of \(\sigma^n\). Indeed, \(D_x \sigma^n(x) = D_x \sigma(x)\), if \(|x| \leq n\), and the derivative is bounded. Regarding the noise term, let us notice that the map \(q \to \int_0^T q_t dW_t\) is linear and continuous, hence weakly continuous. The other terms are easy to treat.

For the uniqueness part it is enough to use a version of Lemma \(\Box\) on finite time horizon. Then we have existence and uniqueness of a solution in finite time horizon and the proof is finished.

\begin{remark}
(a) The introduction of the term \(-r y^n_t\) in \((39)\) is due to the choice of the scalar product used for establishing duality. If one considers a scalar product in \(L^{2-r}\) rather than in \(L^2\) then the additional term \(-r y^n_t\) can be omitted.

(b) An alternative approach to obtain the uniform estimate can be the one following Pardoux \cite{Pardoux1990}. Indeed, applying the Itô formula gives

\[
\mathbb{E}|p^n_t|^2 = 2\mathbb{E} \int_t^T \left[ \langle p^n_s, D_x b(\bar{x}_s, \bar{u}_s)p^n_s \rangle + \langle p^n_s, D_x \sigma^n(\bar{x}_s, \bar{u}_t)^T q^n_s \rangle + \langle p^n_s, D_x f(\bar{x}_s, \bar{u}_s) \rangle \right] ds
\]

\[
- 2r\mathbb{E} \int_t^T |p^n_s|^2 ds - \mathbb{E} \int_t^T \|q^n_s\|^2 ds,
\]

which, thanks to the joint monotonicity of \(b, \sigma^n\) and weighted Young inequality, produces

\[
\mathbb{E}|p^n_t|^2 + (2r - \varepsilon - 2c_1) \mathbb{E} \int_t^T |p^n_s|^2 ds + \left(1 - \frac{1}{2} \right) \mathbb{E} \int_t^T \|q^n_s\|^2 ds
\]

\[
\leq \frac{1}{\varepsilon} \mathbb{E} \int_t^T |D_x f(\bar{x}_s, \bar{u}_s)|^2 ds,
\]

for all \(t \in [0, T]\), \(\varepsilon > 0\) and \(r > c_1\). Again, we have a uniform estimate (in \(n\)) for the left hand side and the relative compactness argument can be applied as before. Note that this approach gives another restriction on \(r\) than the one used in the proof.

(c) All the results of this section can be made more general when considering general weighted Young inequality \(ab \leq \frac{a^p}{p} + \frac{1}{2p} b^2\), \(p > 0\) in \((36)\) rather than the usual Young inequality with \(p = 1\).

Now we are ready for the following

\begin{theorem}
Under Hypotheses (H1) – (H5), there exists \(r > 0\) such that equation \((35)\) admits a unique solution \((p, q)\) which belongs to \(L^{2-r}\)(\(\mathbb{R}^+; \mathbb{R}^n\)) \(\times \) \(L^{2-r}\)(\(\mathbb{R}^+; \mathbb{R}^{n \times d}\)).
\end{theorem}

\begin{proof}
Following Peng and Shi \cite{Peng2000}, Theorem 4, define for all \(k \in \mathbb{N}\)

\[
\varphi^k_t := D_x f(\bar{x}_t, \bar{u}_t)\chi_{[0,k]}(t),
\]

which converges to \(D_x f(\bar{x}_t, \bar{u}_t)\) as \(k \to \infty\). We define the solution to the following approximate equation on infinite time horizon

\[
dp^k_t = - \left[ D_x b(\bar{x}_t, \bar{u}_t)^T p^k_t + D_x \sigma(\bar{x}_t, \bar{u}_t)^T q^k_t - \varphi^k_t - r p^k_t \right] dt + q^k_t dW_t,
\]

as a process solving the following BSDE on a finite time horizon

\[
\begin{cases}
dp^k_t = - \left[ D_x b(\bar{x}_t, \bar{u}_t)^T p^k_t + D_x \sigma(\bar{x}_t, \bar{u}_t)^T q^k_t - \varphi^k_t - r p^k_t \right] dt + q^k_t dW_t, \\
p^k_T = 0,
\end{cases}
\]

(44)
and which is identically zero for \( t \in (k, \infty) \). Such solution exists for each \( k \) due to Theorem \( 3 \). Using the a priori estimate given in Lemma \( 3 \) it is easy to see that there exists \( r \) such that the sequence of solutions \((p^k_t, q^k_t)\) forms a Cauchy sequence in \( L_\mathcal{F}^{2-r}(\mathbb{R}^n; \mathbb{R}^n) \times L_\mathcal{F}^{2-r}(\mathbb{R}^n; \mathbb{R}^{n \times d}) \) and that the limiting processes \((p_t, q_t)\) solves (35). Uniqueness is straightforward due to Lemma \( 3 \). 

7. SECOND ADJOINT

The second adjoint equation has the following form

\[
-dP(t) = \left[ D_x b(\bar{X}_t, \bar{u}_t) + P_t D_x b(\bar{X}_t, \bar{u}_t) \right. \\
+ \sum_{j=1}^d D_x \sigma^j(\bar{X}_t, \bar{u}_t) P_t D_x \sigma^j(\bar{X}_t, \bar{u}_t) \\
+ \sum_{j=1}^d \left( D_x \sigma^j(\bar{X}_t, \bar{u}_t)^T Q_t^j + Q_t^j D_x \sigma^j(\bar{X}_t, \bar{u}_t) \right) \\
+ D_x^2 H(\bar{X}_t, \bar{u}_t, p_t, q_t) - r_t P_t \right] dt - \sum_{j=1}^d Q_t^j dW_t^j.
\]

For a detailed discussion of the role of this equation see e.g. [24]. We can see that the term
\[
\sum_{j=1}^d D_x \sigma^j(\bar{X}_t, \bar{u}_t) P_t D_x \sigma^j(\bar{X}_t, \bar{u}_t)
\]
destroy the dissipative behaviour of the dynamics in the sense that, in general

\[
\left\langle \sum_{j=1}^d D_x \sigma^j(\bar{X}_t, \bar{u}_t) P_t D_x \sigma^j(\bar{X}_t, \bar{u}_t), P_t \right\rangle_2 \leq c P_t \|P_t\|_2^2.
\]

Nontheless, see Remark 4 for one particular case. The lack of dissipativity prevents us from finding an a priori estimate of the solution. Hence the argument we adopted to solve the first adjoint is no longer helpful. The only information that can be useful to study the process \( P_t \) comes from the first variation equation (27). It can be shown that \( P_t \) is dual (in some sense explained later) to the process \( Y_t^\varepsilon \) defined as \( Y_t^\varepsilon = \bar{y}_t^\varepsilon (\bar{y}_t^\varepsilon)^T \). It is not difficult to verify that \( Y_t^\varepsilon \) is a symmetric and positive (semi)definite matrix process. By using Itô formula it can be also shown that it is a solution to the following (matrix-valued) SDE

\[
dY_t^\varepsilon = \left[ D_x b(\bar{X}_t, \bar{u}_t)Y_t^\varepsilon + Y_t^\varepsilon D_x b(\bar{X}_t, \bar{u}_t)^T \\
+ \sum_{j=1}^d D_x \sigma^j(\bar{X}_t, \bar{u}_t) Y_t^\varepsilon D_x \sigma^j(\bar{X}_t, \bar{u}_t)^T + \Gamma(t) \right] dt \\
+ \sum_{j=1}^d \left[ D_x \sigma^j(\bar{X}_t, \bar{u}_t) Y_t^\varepsilon + Y_t^\varepsilon D_x \sigma^j(\bar{X}_t, \bar{u}_t)^T + \Lambda^j(t) \right] dW_t^j,
\]

\( Y_0^\varepsilon = 0, \)

where

\[
\Gamma(t) := \sum_{j=1}^d \delta \sigma^j(\bar{X}_t, \bar{u}_t)(\delta \sigma^j(\bar{X}_t, \bar{u}_t))^T + \sum_{j=1}^d D_x \sigma^j(\bar{X}_t, \bar{u}_t) y_t^\varepsilon (\delta \sigma^j(\bar{X}_t, \bar{u}_t))^T \\
+ \sum_{j=1}^d \delta \sigma^j(\bar{X}_t, \bar{u}_t)(y_t^\varepsilon)^T D_x \sigma^j(\bar{X}_t, \bar{u}_t)^T,
\]

and

\[
\Lambda(t) = \sum_{j=1}^d \Lambda^j(t) := \sum_{j=1}^d \left[ \delta \sigma^j(\bar{X}_t, \bar{u}_t)(y_t^\varepsilon)^T + y_t^\varepsilon (\delta \sigma^j(\bar{X}_t, \bar{u}_t))^T \right].
\]

We also have the following
Proposition 3. Under Hypotheses (H1)-(H5), there exists $r \in \mathbb{R}$ such that equation (47) has a unique solution $Y_t^r \in L^2_{\mathcal{F}}(\mathbb{R}^n; \mathbb{R}^{n \times n})$ and the following holds

$$
E \int_0^\infty e^{-rt} \|Y_t^r\|_2^2 dt \leq KE \int_0^\infty e^{-rt} \|\Gamma_t\|_2^2 dt + K \sum_{j=1}^d E \int_0^\infty e^{-rt} \|\Lambda_t^j\|_2^2 dt,
$$

(50)

for some $K > 0$.

Proof. See Appendix. □

The crucial point here is that Proposition 3 holds true if and only if $Y_t^r$ is the solution to equation (47), i.e. for $\Gamma$ and $\Lambda$ given by (48) and (49). For general (nonsymmetric) forcing terms $\Gamma$ and $\Lambda \in L^2_{\mathcal{F}}(\mathbb{R}^n; \mathbb{R}^{n \times n})$ the corresponding process $Y_t$ can not be decomposed anymore as $y_t^T y_t^T$ for some process $y_t$. Due to this fact, it is not possible to apply a classical duality argument (as in [22] or [24]) to extract some information for $P$ and the corresponding BSDE.

Remark 4. Note that in the case of $\sigma$ Lipschitz (thus $D_x \sigma$ bounded) it is quite easy to derive the dissipativity of $P$ in sense of (40). This particular case can be treated in the same way as in the section on first adjoint equation.

7.1. Construction of $P_t$. Here we propose a different way to construct the process $P_t$ following ideas of Fuhrman et al. [7]. More precisely, will show that there exists $r > 0$ and a well defined matrix-valued process $P_t$ such that the following duality relation holds

$$
E \int_0^\infty e^{-rt} \operatorname{Tr} \left[ D_x^2 H(\bar{X}_t, \bar{u}_t, p_t) Y_t^r \right] dt = \sum_{j=1}^d E \int_0^\infty e^{-rt} \left( P_t \delta \sigma^j(\bar{X}_t, \bar{u}_t), \delta \sigma^j(\bar{X}_t, \bar{u}_t) \right) dt + o(\varepsilon).
$$

(51)

Once we have this relation, it is easy to prove the stochastic maximum principle using usual arguments. The strategy to do so will be the following.

Dual identity satisfied by $P$: For $t \geq 0$ and an arbitrary vector $\gamma \in \mathbb{R}^n$, let us consider the following SDE

$$
\begin{cases}
   dy_t^{l,\gamma} = D_x b(\bar{X}_s, \bar{u}_s) y_s^{l,\gamma} ds + \sum_{j=1}^d D_x \sigma^j(\bar{X}_s, \bar{u}_s) y_s^{l,\gamma} dW_s^j, & s \geq t, \\
   y_t^{l,\gamma} = \gamma.
\end{cases}
$$

(52)

By repeating the arguments by Yong and Zhou [24], Chapter 3, the SDE for the product $y_s^{l,\eta}(y_s^{l,\gamma})^T$ is of the form (with the notation $A_t \equiv D_x b(\bar{X}_t, \bar{u}_t)$ and $B_t^j \equiv D_x \sigma^j(\bar{X}_t, \bar{u}_t)$)

$$
d \left( y_s^{l,\eta}(y_s^{l,\gamma})^T \right) = \left[ A_s y_s^{l,\eta}(y_s^{l,\gamma})^T + y_s^{l,\eta}(y_s^{l,\gamma})^T A_s^T + \sum_{j=1}^d B_s^j y_s^{l,\eta}(y_s^{l,\gamma})^T (B_s^j)^T \right] ds + \left[ \sum_{j=1}^d B_s^j y_s^{l,\eta}(y_s^{l,\gamma})^T + y_s^{l,\eta}(y_s^{l,\gamma})^T (B_s^j)^T \right] dW_s^j.
$$

(53)

Suppose for a moment that we are able to find a solution to equation (45) in $L^2_{\mathcal{F}}(\mathbb{R}^n; \mathcal{S}) \times (L^2_{\mathcal{F}}(\mathbb{R}^n; \mathcal{S}))^d$ for some $r > 0$. Noting that $\langle P_t y_s^{l,\eta}, y_s^{l,\gamma} \rangle = \operatorname{Tr}(P_s y_s^{l,\eta}(y_s^{l,\gamma})^T)$ and using equation (52), it follows by the Itô formula that for all $[t, T]$ we have $\mathbb{P}$-almost surely

$$
e^{-rt} \langle P_t \eta, \gamma \rangle = \mathbb{E}^{\mathcal{F}_t} \left[ e^{-rt} \langle P_t y_t^{l,\eta}, y_t^{l,\gamma} \rangle \right] = \mathbb{E}^{\mathcal{F}_t} \left[ e^{-rT} \langle P_T y_T^{l,\eta}, y_T^{l,\gamma} \rangle \right] + \mathbb{E}^{\mathcal{F}_t} \int_t^T e^{-rs} \langle D_x^2 H(s) y_s^{l,\eta}, y_s^{l,\gamma} \rangle ds,
$$

(54)
where we have used the notation $D^2_t H(t) := D^2_t H(\bar{X}_t, \bar{u}_t, p_t, q_t)$ for the forcing term in the equation for $P$. Since the processes $P(\cdot)$ and $y^{t,\eta}(\cdot, \gamma)^T$ are assumed to be in some appropriate exponentially-weighted spaces, there has to be a sequence of times $(T_n)_{n \geq 1}$ with $T_n \nearrow +\infty$ as $n \to +\infty$ such that $P$-almost surely

$$\lim_{n \to +\infty} \mathbb{E}^F_t \left[ e^{-r T_n} \langle P_{T_n} y^{t,\eta}_{T_n}, y^{l,\gamma}_{T_n} \rangle \right] = 0. \quad (55)$$

Passing to the limit along the above sequence $(T_n)_{n \geq 1}$ produces the following formal relation

$$\langle P_t \eta, \gamma \rangle = \mathbb{E}^F_t \int_t^{\infty} e^{-r(s-t)} \langle D^2_s H(s) y^{s,\eta}_s, y^{l,\gamma}_s \rangle \ ds, \quad (56)$$

which can be used to define the process $P_t$. Our aim is to show that the right hand side of $(56)$ actually defines a continuous bilinear form that can be used to prove $(55)$ without any reference to the second adjoint BSDE.

**Existence of $P$:** The following estimates on $(y^{t,\eta}_s)_{s \geq t}$ are crucial to prove continuity of the bilinear form.

**Proposition 4.** Let $\eta \in \mathbb{R}^n$ and assume that Hypotheses (H1)-(H4) hold. Then there is a unique solution $(y^{t,\eta}_s)_{s \geq t} \in L^{2-r}_F(\mathbb{R}^n; \mathbb{R}^n)$ to the equation $(52)$ for some $r$. Moreover, there exists a constant $C > 0$ such that for $t \geq 0$ and $s \geq t$

$$\sup_{s \geq t} \mathbb{E}^F_t \left[ e^{-r t} |y^{t,\eta}_s|^4 \right] \leq C |\eta|^4, \quad \mathbb{P} - \text{a.s.} \quad (57)$$

and for all $h > 0$, $0 \leq t \leq t + h$ and $s \geq t + h$

$$e^{-r s} \mathbb{E} |y^{t+h,\eta}_s - y^{t,\eta}_s|^4 \leq C h. \quad (58)$$

**Proof.** Let us choose $r > 2c_1/2$. The existence follows immediately by Theorem 2 and the proof of $(57)$ it is a easy consequence of Lemma 1 with the additional requirement $r > 2 \max\{c_1/2, c_3\}$. To prove the continuity property $(58)$ let us denote $z_s = y^{t+h,\eta}_s - y^{t,\eta}_s$ then, for $s \geq t + h$, we have by the Itô formula

$$e^{-r s} \mathbb{E} |z_s|^4 = e^{-r(t+h)} \mathbb{E} |\eta - y^{t+h,\eta}|^4 - r \mathbb{E} \int_t^{s} e^{-r \tau} |z_\tau|^4 \ d\tau + \mathbb{E} \int_t^{s} e^{-r \tau} \langle D_x b(\bar{X}_\tau, \bar{u}_\tau) z_\tau, z_\tau \rangle \ d\tau + \sum_{j=1}^{d} \mathbb{E} \int_t^{s} e^{-r \tau} \langle D_x \sigma^j(\bar{X}_\tau, \bar{u}_\tau) z_\tau, z_\tau \rangle^2 \ d\tau.$$

Using the same estimate of Lemma 1 we end up with

$$e^{-r s} \mathbb{E} |y^{t+h,\eta}_s - y^{t,\eta}_s|^4 \leq K e^{-r(t+h)} \mathbb{E} |\eta - y^{t+h,\eta}|^4, \quad (59)$$

which we can control in the following form

$$\mathbb{E} |\eta - y^{t+h,\eta}|^4 = \mathbb{E} \int_t^{t+h} |D_x b(\bar{X}_\tau, \bar{u}_\tau) y^{t,\eta}_\tau|^4 \ d\tau + \sum_{j=1}^{d} \mathbb{E} \int_t^{t+h} |D_x \sigma^j(\bar{X}_\tau, \bar{u}_\tau) y^{t,\eta}_\tau|^4 dW^j_\tau \leq C \mathbb{E} \int_t^{t+h} |D_x b(\bar{X}_\tau, \bar{u}_\tau) y^{t,\eta}_\tau|^4 \ d\tau + \sum_{j=1}^{d} \mathbb{E} \int_t^{t+h} |D_x \sigma^j(\bar{X}_\tau, \bar{u}_\tau) y^{t,\eta}_\tau|^4 d\tau.$$
we have to prove that the map \((\gamma, \eta)\). For a recent and elegant proof of this fact see \cite{14}. Concerning joint measurability of \(P_t\), its proof is given in \cite{7}.

Moreover, \(\sup_{t\geq0}E||P_t||^2 < \infty\) and for \(\varepsilon > 0\) we have that

\[ E||((P_{t+\varepsilon} - P_t)\gamma, \eta)|| \rightarrow 0. \]  

Proof. For \(\gamma \in \mathbb{R}^n\) fixed, let us define \(\langle P_t\gamma, \eta \rangle\) by the formula given in the statement. To do so we have chosen an arbitrary version of the conditional expectation. To construct the process \(P_t\) we have to prove that the map \((\gamma, \eta) \mapsto \langle P_t\gamma, \eta \rangle\) is a continuous bilinear form. Note that

\[
\left| E^F_t\int_t^\infty e^{-r(s-t)} \langle D_x^2H(s)y_s^l, y_s^l\rangle \, ds \right|
\leq E^F_t\int_t^\infty e^{-r(s-t)} |D_x^2H(s)||y_s^l||y_s^l| \, ds
\leq C \int_t^\infty \left( e^{-r(s-t)}E^F_t|D_x^2H(s)|^p \right)^{1/p} \left( e^{-r(s-t)}E^F_t|y_s^l|^{2q} \right)^{\theta_p} \, ds
\leq C||\gamma|| \left( \int_t^\infty e^{-r(s-t)}E^F_t|D_x^2H(s)|^p \, ds \right)^{1/p},
\]

where we used conditional Hölder inequality with \(p \in (1, 2), q = \frac{p}{p-1} > 2\) and estimate \(57\). \(r > 0\) can be chosen such that \(\int_t^\infty e^{-r\tau}E^F_t|D_x^2H(s)|^p \, ds < \infty\). This can be seen from the definition of the Hamiltonian, the estimates on first adjoint processes and the polynomial growth of the coefficients. Further, there exists a set \(N\) such that \(P(N) = 0\) and for \(\omega \notin N\),

\[ ||\langle P_t(\omega)\eta, \gamma \rangle|| \leq C||\gamma||. \]

If we set \(P_t(\omega) = 0\) for \(\omega \in N\), by now we have constructed an adapted process \(P_t\) which satisfies equation \(61\). The symmetry of the process \(P\) is obtained easily by symmetry of \(D_x^2H(s)\).

To construct a progressive modification of \(P_t\), it is sufficient to prove that the map \((\omega, t) \mapsto P_t(\omega)\) is \(F \otimes \mathcal{B}(\mathbb{R}_+) \setminus \mathcal{B}(\mathbb{R}^{n\times n})\)–measurable (i.e. it is a jointly measurable process). Here, \(\mathcal{B}(\mathbb{R}^{n\times n})\) stands for a Borel \(\sigma\)-field induced by the norm \(|| \cdot ||_2\) on \(\mathbb{R}^{n\times n}\). If we prove that \(P\) is an \((F_t)\)–adapted and jointly measurable process then there is an \((F_t)\)–progressive version of \(P\). For a recent and elegant proof of this fact see \cite{14}. Concerning joint measurability of \(P\), its proof is given in \cite{7}. In that paper, in fact, even the existence of a progressive version in infinite dimensional setting is provided without any reference to the classical result.
To show that (62) holds, let us write
\[
\langle (P_{t+\varepsilon} - P_t) \eta, \gamma \rangle = \left( \mathbb{E} \mathcal{F}_{t+\varepsilon} \mathcal{F}_t \right) \int_t^{t+\varepsilon} e^{-r(s-t)} \langle D_x^2 H(s) y_s^{1+\varepsilon, \eta}, y_s^{1+\varepsilon, \gamma} \rangle \, ds
\]
\[
- \mathbb{E} \mathcal{F}_{t+\varepsilon} \int_t^{t+\varepsilon} e^{-r(s-t)} \langle D_x^2 H(s) y_s^{1, \eta}, y_s^{1+\varepsilon, \gamma} \rangle \, ds
\]
\[
+ \mathbb{E} \mathcal{F}_{t+\varepsilon} \int_t^{t+\varepsilon} e^{-r(s-t-\varepsilon)} \langle (D_x^2 H(s) y_s^1, \eta), y_s^{1+\varepsilon, \gamma} \rangle - \langle D_x^2 H(s) y_s^{1, \eta}, y_s^{1, \gamma} \rangle \, ds
\]
\[
+ \mathbb{E} \mathcal{F}_{t+\varepsilon} \int_t^{t+\varepsilon} \left( e^{-r(s-t-\varepsilon)} - e^{-r(s-t)} \right) \langle D_x^2 H(s) y_s^{1, \eta}, y_s^{1, \gamma} \rangle \, ds.
\]

The first summand on the right hand side goes to zero in \( L^1(\Omega) \) as \( \varepsilon \to 0 \) thanks to the Lévy downward martingale convergence theorem (note that we have UC filtration \( (\mathcal{F}_t)_{t \geq 0} \), the second one and the last one tend to zero in \( L^1(\Omega) \) by dominated convergence theorem. Regarding the third term the result easily follows by using (58). Indeed we can rewrite it as follows
\[
\mathbb{E} \mathcal{F}_{t+\varepsilon} \int_t^{t+\varepsilon} e^{-r(s-t-\varepsilon)} \langle D_x^2 H(s) (y_s^{1+\varepsilon, \eta} - y_s^{1+\varepsilon, \gamma}), y_s^{1+\varepsilon, \gamma} \rangle \, ds
\]
\[
+ \mathbb{E} \mathcal{F}_{t+\varepsilon} \int_t^{t+\varepsilon} e^{-r(s-t-\varepsilon)} \langle D_x^2 H(s) y_s^{1, \eta}, y_s^{1, \gamma} - y_s^{1+\varepsilon, \gamma} \rangle \, ds = I_1 + I_2.
\]

Using Hölder inequality with \( p \in (1, 2), q = \frac{p}{p-1} > 2 \), the first addendum \( I_1 \) can be estimate by
\[
I_1 \leq e^{t+\varepsilon} \int_t^{t+\varepsilon} \left( e^{-rs} \mathbb{E} \mathcal{F}_{t+\varepsilon} |D_x^2 H(s)|^p |y_s^{1+\varepsilon, \eta} - y_s^{1+\varepsilon, \gamma}|^2 q \right) ^{\frac{1}{2q}} \cdot \left( e^{-rs} \mathbb{E} \mathcal{F}_{t+\varepsilon} |y_s^{1+\varepsilon, \gamma}|^2 q \right) ^{\frac{1}{2q}} \, ds.
\]

Repeating the same estimate for the second addendum \( I_2 \), using Lemma 1 and (58) we get the required result. \qed

Remark 5. If \( F, G \) are random variables in \( L^2(\Omega) \) measurable with respect to \( \mathcal{F}_t \) then it is true that
\[
\langle P_t F, G \rangle = \mathbb{E} \mathcal{F}_t \int_0^\infty e^{-r(s-t)} \langle D_x^2 H(s) y_s^{1, F}, y_s^{1, G} \rangle \, ds, \quad \mathbb{P} \text{- a.s.}
\]
The proof follows by applying similar procedure as in Peng and Shi, [18], Theorem 13.

Proposition 6. Let \( (y_r^\varepsilon)_{r \geq 0} \) be a solution to the first variation equation (27). Then there exists \( r > 0 \) such that the following relations hold true.
\[ i) \quad e^{-r(t_0+\varepsilon)} \mathbb{E} \langle (P_{t_0+\varepsilon} - P_{t_0}) y_{t_0+\varepsilon}, y_{t_0+\varepsilon}^\varepsilon \rangle = o(\varepsilon), \]
\[ ii) \quad e^{-r(t_0+\varepsilon)} \mathbb{E} \langle P_{t_0} y_{t_0+\varepsilon}, y_{t_0+\varepsilon}^\varepsilon \rangle \]
\[ = \sum_{j=1}^d \mathbb{E} \int_0^\infty e^{-rs} \langle P_s \delta \sigma^j (\bar{X}_s, \bar{u}_s), \delta \sigma^j (\bar{X}_s, \bar{u}_s) \rangle \, ds + o(\varepsilon). \]

Proof. (i) From Proposition 1(ii) we know that there exists \( r \) such that
\[
\left( e^{-r(t_0+\varepsilon)} \mathbb{E} |y_{t_0+\varepsilon}^\varepsilon|^{2k} \right) ^{1/2k} \leq C, \quad k \geq 1,
\]
and by the Markov inequality, for every \( \delta > 0 \) we have that
\[
\mathbb{P} \left( |y_{t_0+\varepsilon}^\varepsilon| > C \delta^{-1/4} \right) \leq e^{r(t_0+\varepsilon)} \delta.
\]
If we denote \( \Omega_{\delta, \varepsilon} \) the event \( \{ \varepsilon^{-1/2} y_{t_0+\varepsilon}^\varepsilon \in B_{C \delta^{-1/4}} \} \), where \( B_{C \delta^{-1/4}} \) is the centred ball with radius \( \delta^{-1/4} \), then it holds
\[
\mathbb{P}(\Omega_{\delta, \varepsilon}^\varepsilon) \leq e^{r(t_0+\varepsilon)} \delta.
\]
Now we rewrite (i) in the following form
\[
e^{-r(t_0+\varepsilon)}\mathbb{E}\left\langle (P_{t_0+\varepsilon} - P_{t_0}) e^{-1/2 y_{t_0+\varepsilon}^\varepsilon}, e^{-1/2 y_{t_0+\varepsilon}^\varepsilon}\right\rangle
= e^{-r(t_0+\varepsilon)}\mathbb{E}\left\langle (P_{t_0+\varepsilon} - P_{t_0}) e^{-1/2 y_{t_0+\varepsilon}^\varepsilon}, e^{-1/2 y_{t_0+\varepsilon}^\varepsilon}\right\rangle 1_{\Omega_4^\varepsilon}
+ e^{-r(t_0+\varepsilon)}\mathbb{E}\left\langle (P_{t_0+\varepsilon} - P_{t_0}) e^{-1/2 y_{t_0+\varepsilon}^\varepsilon}, e^{-1/2 y_{t_0+\varepsilon}^\varepsilon}\right\rangle 1_{\Omega_6^\varepsilon}
=: A_1^\varepsilon + A_2^\varepsilon.
\]
The first term can be easily treated by the Hölder inequality, Proposition 5 and estimates (60), (67), respectively. Hence, the estimate reads
\[
|A_1^\varepsilon| \leq \left( e^{-r(t_0+\varepsilon)}\mathbb{E}\|P_{t_0+\varepsilon} - P_{t_0}\|^2 \right)^{1/2}
\cdot \left( e^{-r(t_0+\varepsilon)}\mathbb{E}|e^{-1/2 y_{t_0+\varepsilon}^\varepsilon}|^8 \right)^{1/4} \left( e^{-r(t_0+\varepsilon)}\mathbb{P}(\Omega_{\varepsilon}^\varepsilon) \right)^{1/4}
\leq C\delta^{3/4}.
\] (68)

Regarding the second term, we have that
\[
|A_2^\varepsilon| \leq e^{-r(t_0+\varepsilon)}\mathbb{E} \left[ \sup_{x \in B_{C\delta^{-1/4}}} \left| \langle (P_{t_0+\varepsilon} - P_{t_0}) x, x \rangle 1_{\Omega_6^\varepsilon} \right| \right].
\]
Since \( B_{C\delta^{-1/4}} \) is compact, there exist \( N_\delta \) open balls \( B_{x_i, \delta} \) which cover it. Moreover, for all \( x \in B_{C\delta^{-1/4}} \) we can choose \( i \) such that \( |x - x_i| \leq \delta \). Then
\[
\langle (P_{t_0+\varepsilon} - P_{t_0}) x, x \rangle = \langle (P_{t_0+\varepsilon} - P_{t_0}) x_i, x_i \rangle - \langle (P_{t_0+\varepsilon} - P_{t_0}) (x - x_i), (x - x_i) \rangle
+ 2 \langle (P_{t_0+\varepsilon} - P_{t_0}) x, (x - x_i) \rangle
= \langle (P_{t_0+\varepsilon} - P_{t_0}) x_i, x_i \rangle + \|P_{t_0+\varepsilon} - P_{t_0}\|_{\infty} \delta^2
+ 2\|P_{t_0+\varepsilon} - P_{t_0}\|_{\infty} |x| \delta,
\] (69)
where, for a generic matrix \( T \in \mathbb{R}^{n \times n} \), we have used \( \|T\|_{\infty} := \sup\{|\langle Tx, y \rangle | : x, y \in \mathbb{R}^n, |x| \leq 1, |y| \leq 1 \} \). Taking supremum and expectation we obtain
\[
|A_2^\varepsilon| \leq \sum_{i=1}^{N_\delta} \mathbb{E} \| (P_{t_0+\varepsilon} - P_{t_0}) x_i, x_i \| + C \left( \delta^2 + \delta^{3/4} \right).
\] (70)
If we let \( \varepsilon \to 0 \) and use (62) it follows that
\[
\limsup_{\varepsilon \to 0} |A_2^\varepsilon| \leq C \left( \delta^2 + \delta^{3/4} \right),
\]
hence \( |A_1^\varepsilon| + |A_2^\varepsilon| \to 0 \), when \( \delta \to 0 \) and the proof of (i) is finished.

(ii) Let us rewrite \( e^{-r(t_0+\varepsilon)}\mathbb{E} \langle P_{t_0} y_{t_0+\varepsilon}^\varepsilon, y_{t_0+\varepsilon}^\varepsilon \rangle \) in the following form
\[
e^{-r(t_0+\varepsilon)}\mathbb{E} \langle P_{t_0} y_{t_0+\varepsilon}^\varepsilon, y_{t_0+\varepsilon}^\varepsilon \rangle = \mathbb{E} \left[ \text{Tr} \left\{ P_{t_0} \left( e^{-\frac{t}{t_0+\varepsilon}} y_{t_0+\varepsilon}^\varepsilon \right) \left( e^{-\frac{t}{t_0+\varepsilon}} y_{t_0+\varepsilon}^\varepsilon \right)^T \right\} \right].
\]
Thanks to the Itô formula and equation (47), we obtain
\[
d \left( e^{-r s} Y_s^\varepsilon \right) = e^{-r s} \left[ -r Y_s^\varepsilon + D_x b(\tilde{X}_s, \tilde{u}_s) Y_s^\varepsilon + Y_s^\varepsilon D_x b(\tilde{X}_s, \tilde{u}_s)^T \right.
+ \sum_{j=1}^d D_x \sigma_j^i(\tilde{X}_s, \tilde{u}_s) Y_s^\varepsilon D_x \sigma_j^i(\tilde{X}_s, \tilde{u}_s)^T + \Gamma(s) \big] ds
+ \sum_{j=1}^d e^{-r s} \left[ D_x \sigma_j^i(\tilde{X}_s, \tilde{u}_s) Y_s^\varepsilon + Y_s^\varepsilon D_x \sigma_j^i(\tilde{X}_s, \tilde{u}_s)^T + \Lambda_j(s) \right] dW_s^j,
\] (71)
where we have used the notation \( Y_s^\varepsilon = y_{t_0+\varepsilon}(y_{t_0+\varepsilon})^T \) and \( \Gamma(s), \Lambda_j(s) \) are as in (15), (19). Now, by taking conditional expectation with respect to \( F_{t_0} \) and rewriting the equation in integral form from \( t_0 \) to
s (recall Remark 2) it follows that
\[ \mathbb{E}^{\mathcal{F}_0} \left( e^{-rsY^s} \right) = \mathbb{E}^{\mathcal{F}_0} \int_{t_0}^s e^{-r\tau} \left[ -rY^s + D_x b(X^s, \bar{u}^s)Y^s + Y^s D_x b(X^s, \bar{u}^s)^T \right] d\tau \]
\[ + \sum_{j=1}^d \mathbb{E}^{\mathcal{F}_0} \int_{t_0}^s \left[ D_x \sigma^j(X^s, \bar{u}^s)Y^s D_x \sigma^j(X^s, \bar{u}^s)^T + \Gamma(\tau) \right] d\tau. \]

Hence, taking into account the definition of \( \Gamma \) in (13), multiplying by \( P_{t_0} \), setting \( s = t_0 + \varepsilon \) and taking expectation, we arrive at
\[ e^{-r(t_0+\varepsilon)} \mathbb{E} \left( P_{t_0} y_{t_0+\varepsilon}, y_{t_0+\varepsilon}^c \right) \]
\[ = \int_{t_0}^{t_0+\varepsilon} e^{-r\tau} \mathbb{E} \left( \operatorname{Tr} \left\{ P_{t_0} \left[ -rY^s + D_x b(X^s, \bar{u}^s)Y^s + Y^s D_x b(X^s, \bar{u}^s)^T \right] \right\} \right] d\tau \]
\[ + \sum_{j=1}^d \int_{t_0}^{t_0+\varepsilon} e^{-r\tau} \mathbb{E} \left( \operatorname{Tr} \left\{ P_{t_0} \left( D_x \sigma^j(X^s, \bar{u}^s)Y^s D_x \sigma^j(X^s, \bar{u}^s)^T \right) \right\} \right] d\tau \]
\[ + \sum_{j=1}^d \int_{t_0}^{t_0+\varepsilon} e^{-r\tau} \mathbb{E} \left( \operatorname{Tr} \left\{ P_{t_0} \left( \delta \sigma^j(X^s, \bar{u}^s) \left( \delta \sigma^j(X^s, \bar{u}^s)^T \right) \right) \right\} \right] d\tau \]
\[ + \sum_{j=1}^d \int_{t_0}^{t_0+\varepsilon} e^{-r\tau} \mathbb{E} \left( \operatorname{Tr} \left\{ P_{t_0} \left( \delta \sigma^j(X^s, \bar{u}^s) y^c \left( \delta \sigma^j(X^s, \bar{u}^s)^T \right) \right) \right\} \right] d\tau \]
\[ + \sum_{j=1}^d \int_{t_0}^{t_0+\varepsilon} e^{-r\tau} \mathbb{E} \left( \operatorname{Tr} \left\{ P_{t_0} \left( \delta \sigma^j(X^s, \bar{u}^s) y^c D_x \sigma^j(X^s, \bar{u}^s)^T \right) \right\} \right] d\tau. \]

We will show that using the estimate for \( y^c \) in the form of (66), the only term which is not of order \( o(\varepsilon) \) is the third one. Therefore, the final equality will read
\[ e^{-r(t_0+\varepsilon)} \mathbb{E} \left( P_{t_0} y_{t_0+\varepsilon}, y_{t_0+\varepsilon}^c \right) \]
\[ = \sum_{j=1}^d \mathbb{E} \int_{t_0}^{t_0+\varepsilon} e^{-r\tau} \left( P_{t_0} \delta \sigma^j(X^s, \bar{u}^s), \delta \sigma^j(X^s, \bar{u}^s) \right) d\tau \]
\[ + o(\varepsilon). \] \hfill (72)

For sake of completeness, let us estimate the second term as
\[ \sum_{j=1}^d \int_{t_0}^{t_0+\varepsilon} e^{-r\tau} \mathbb{E} \left( \operatorname{Tr} \left\{ P_{t_0} \left( D_x \sigma^j(X^s, \bar{u}^s)Y^s D_x \sigma^j(X^s, \bar{u}^s)^T \right) \right\} \right] d\tau \]
\[ = \sum_{j=1}^d \int_{t_0}^{t_0+\varepsilon} e^{-r\tau} \mathbb{E} \left( P_{t_0} D_x \sigma^j(X^s, \bar{u}^s) y^c, D_x \sigma^j(X^s, \bar{u}^s) y^c \right) d\tau \]
\[ \leq \sum_{j=1}^d \int_{t_0}^{t_0+\varepsilon} e^{-r\tau} \mathbb{E} \left( \| P_{t_0} \|_2^2 D_x \sigma^j(X^s, \bar{u}^s)^2 \| y^c \|_2^2 \right) d\tau \]
\[ \leq \sum_{j=1}^d \int_{t_0}^{t_0+\varepsilon} \mathbb{E} \left( e^{-r\tau} \| P_{t_0} \|_2^{2/2} \mathbb{E} \left( e^{-r\tau} \| D_x \sigma^j(X^s, \bar{u}^s) \|_4^4 \right)^{1/2} \right) \]
\[ e^{-r\tau} \| y^c \|_4^{1/2} \right) d\tau, \]

and the order of \( o(\varepsilon) \) now follows by Proposition 3, the polynomial growth of \( D_x \sigma(\cdot) \) and estimate (66), respectively. The remaining terms can be treated in the similar way.

To finalize the proof of (72), it remains to be shown that
\[ \sum_{j=1}^d \mathbb{E} \int_{t_0}^{t_0+\varepsilon} e^{-r\tau} \left( (P_{t_0} - P_{t_0}) \delta \sigma^j(X^s, \bar{u}^s), \delta \sigma^j(X^s, \bar{u}^s) \right) d\tau = o(\varepsilon). \] \hfill (73)

But this is easily obtained by repeating the same arguments as in the proof of (i). The proof of the Proposition is now concluded. \qed
8. Necessary stochastic maximum principle

For our main result we need to recall the notion of the Hamiltonian of the system. Given the control problem, let us define $H: \mathbb{R}^n \times U \times \mathbb{R}^n \times \mathbb{R}^{n \times d} \to \mathbb{R}$ as
\[
H(x, u, p, q) = \langle p, b(x, u) \rangle + \text{Tr} \left[ q^T \sigma(x, u) \right] - f(x, u). \tag{74}
\]

**Theorem 5.** Assume (H1)-(H5) hold and let $(\tilde{X}, \tilde{u})$ be an optimal pair. Then there exist $r > 0$, a pair $(p, q) \in L^2_{\mathcal{F}}(\mathbb{R}^n; \mathbb{R}^n) \times L^2_{\mathcal{F}}(\mathbb{R}^n; \mathbb{R}^{n \times d})$ and a progressively measurable process $(P_t)_{t \geq 0}$ with values in $\mathbb{S}^n$ such that the following variational inequality holds, $\mathbb{P} \otimes dt$-a.e.
\[
H(\tilde{X}_t, v, p_t, q_t) - H(\tilde{X}_t, \tilde{u}_t, p_t, q_t) + \frac{1}{2} \sum_{j=1}^{d} \left\{ P_t (\sigma^j(\tilde{X}_t, v) - \sigma^j(\tilde{X}_t, \tilde{u}_t)), \sigma^j(\tilde{X}_t, v) - \sigma^j(\tilde{X}_t, \tilde{u}_t) \right\} \leq 0,
\]
for every $v \in U$. The pair of processes $(p, q)$ is the unique solution to the first adjoint equation \((33)\). The definition of the process $P_t$ is given in Proposition\([\mathcal{B}]\) and the process satisfies $\sup_{t \geq 0} E\|P_t\|_2^2 < \infty$.

**Remark 6.** A sufficient condition for such $r$ is given in the Appendix.

Before proving the theorem, it is useful to rewrite the variation of cost functional in a suitable form, as the following proposition suggests.

**Proposition 7.** There exists $r > 0$ such that the following expansion holds
\[
J(u^*(\cdot)) - J(\bar{u}(\cdot)) = E \int_0^\infty e^{-rt} \left[ \frac{1}{2} \sum_{j=1}^{d} (q_j^T, \delta \sigma^j(\tilde{X}_t, \tilde{u}_t)) - (p_t, \delta b(\tilde{X}_t, \tilde{u}_t)) + \delta f(\tilde{X}_t, \tilde{u}_t) \right] dt
\]
\[
- \frac{1}{2} E \int_0^\infty e^{-rt} \text{Tr} \left[ D^2_x H(\tilde{X}_t, \tilde{u}_t, p_t, q_t) y^*_t (y^*_t)^T \right] dt + o(\varepsilon),
\]
where $H(\tilde{X}_t, \tilde{u}_t, p_t, q_t)$ is the Hamiltonian of the system computed along the optimal trajectory.

**Proof.** See Appendix. \hfill \Box

Now we are in position to end the proof of the SMP.

**Proof of Theorem**\([\mathcal{B}]\). The difficult step of the proof is to show that the following holds
\[
E \int_0^\infty e^{-rs} \langle D^2_x H(s)y^*_s, y^*_s \rangle ds = \sum_{j=1}^{d} E \int_0^\infty e^{-rs} \langle P_s \delta \sigma^j(\tilde{X}_s, \tilde{u}_s), \delta \sigma^j(\tilde{X}_s, \tilde{u}_s) \rangle ds + o(\varepsilon). \tag{76}
\]
Indeed, if relation \((76)\) holds true then by using Proposition\([\mathcal{A}]\) we get
\[
0 \leq J(u^*(\cdot)) - J(\bar{u}(\cdot)) = E \int_0^\infty e^{-rs} \left[ \frac{1}{2} \sum_{j=1}^{d} (q_j^T, \delta \sigma^j(\tilde{X}_s, \tilde{u}_s)) - (p_s, \delta b(\tilde{X}_s, \tilde{u}_s)) + \delta f(\tilde{X}_s, \tilde{u}_s) \right] dt
\]
\[
- \frac{1}{2} \sum_{j=1}^{d} \int_0^\infty e^{-rs} \langle P_s \delta \sigma^j(\tilde{X}_s, \tilde{u}_s), \delta \sigma^j(\tilde{X}_s, \tilde{u}_s) \rangle ds + o(\varepsilon),
\]
thanks to the optimality of $\bar{u}(\cdot)$. Now the final variational inequality follows by standard arguments, i.e. by using the definition of $\delta \sigma^j, \delta b, \delta f$, noting that $E_\varepsilon = [t_0, t_0 + \varepsilon]$ and by sending $\varepsilon \searrow 0$.

Let us focus on the proof of \((76)\). Recalling Remark\([\mathcal{B}]\) we can rewrite the left hand side of \((76)\) in the following form
\[
E \int_0^\infty e^{-rs} \langle D^2_x H(s)y^*_s, y^*_s \rangle ds
\]
\[
= E \int_{t_0 + \varepsilon}^{t_0 + \varepsilon} e^{-rs} \langle D^2_x H(s)y^*_s, y^*_s \rangle ds + E \int_{t_0 + \varepsilon}^\infty e^{-rs} \langle D^2_x H(s)y^*_s, y^*_s \rangle ds
\]
\[
= E \int_{t_0 + \varepsilon}^{t_0 + \varepsilon} e^{-rs} \langle D^2_x H(s)y^*_s, y^*_s \rangle ds + o(\varepsilon),
\]
where we have used Proposition 1 to estimate the first integral and the identity \( y_s^\varepsilon = y_{s_0}^{t_0 + \varepsilon} y_{t_0 + \varepsilon}^\varepsilon \), for \( s \geq t_0 + \varepsilon \). Taking into account Remark 3, we finally deduce the following decomposition

\[
E \int_0^\infty e^{-rs} (D_x^2 H(s)y_s^\varepsilon, y_s^\varepsilon) ds = e^{-r(t_0 + \varepsilon)} E\langle P_{t_0 + \varepsilon} y_{t_0 + \varepsilon}^\varepsilon, y_{t_0 + \varepsilon}^\varepsilon \rangle + o(\varepsilon)
\]

\[
= e^{-r(t_0 + \varepsilon)} E\langle (P_{t_0 + \varepsilon} - P_{t_0}) y_{t_0 + \varepsilon}^\varepsilon, y_{t_0 + \varepsilon}^\varepsilon \rangle + e^{-r(t_0 + \varepsilon)} E\langle P_{t_0} y_{t_0 + \varepsilon}^\varepsilon, y_{t_0 + \varepsilon}^\varepsilon \rangle + o(\varepsilon).
\]

Finally, by Proposition 6, the proof of the Theorem is now concluded. \( \square \)

9. ACKNOWLEDGEMENTS

The authors wish to thank to Marco Fuhrman and Gianmario Tessitore for encouragement and for many valuable discussions.

10. APPENDIX

10.1. Proof of Proposition 1

Proof. In the following we are going to linearize the equations satisfied by \( \xi^\varepsilon(\cdot), \eta^\varepsilon(\cdot) \) and \( \zeta^\varepsilon(\cdot) \) in order to use the estimate obtained in Lemma 1.

(i) It is easy to see that the equation for \( \xi^\varepsilon(\cdot) \) can be rewritten in the form

\[
d\xi_t^\varepsilon = \left[ G_b(t)\xi_t^\varepsilon + \delta b_t \chi_{E_\varepsilon}(t) \right] dt + \sum_{j=1}^d \left[ G^j_\sigma(t)\xi_t^\varepsilon + \delta \sigma^j_t \chi_{E_\varepsilon}(t) \right] dW_t^j,
\]

where

\[
G_b(t) := \int_0^1 D_x b(x_t + \theta \xi_t^\varepsilon, u_t^\varepsilon) d\theta,
\]

\[
G^j_\sigma(t) := \int_0^1 D_x \sigma^j_t(x_t + \theta \xi_t^\varepsilon, u_t^\varepsilon) d\theta.
\]

Thanks to Hypothesis (H4) we can apply Lemma 1 and obtain (the constant \( K > 0 \) varies from line to line)

\[
sup_{t \in \mathbb{R}_+} e^{-rt} \mathbb{E} \left[ \left| \xi_t^\varepsilon \right|^{2k} \right] \leq K \left[ \int_0^\infty e^{-\frac{\theta}{2} t} \left( \mathbb{E} \left| \delta b_t \chi_{E_\varepsilon}(t) \right|^{2k} \right)^\frac{1}{2k} dt \right]^{2k}
\]

\[
+ K \sum_{j=1}^d \left[ \int_0^\infty e^{-\frac{\theta}{2} t} \left( \mathbb{E} \left| \delta \sigma^j_t \chi_{E_\varepsilon}(t) \right|^{2k} \right)^\frac{1}{2k} dt \right]^{2k}
\]

\[
\leq K \left[ \int_{E_\varepsilon} \left( e^{-\frac{r}{2} t} \left( \mathbb{E} \left| b(\bar{X}_t, u_t^\varepsilon) - b(\bar{X}_t, \bar{u}_t) \right|^{2k} \right)^\frac{1}{2k} dt \right)^{2k}
\]

\[
+ K \sum_{j=1}^d \left[ \int_{E_\varepsilon} \left( e^{-\frac{r}{2} t} \left( \mathbb{E} \left| \sigma^j_t(\bar{X}_t, u_t^\varepsilon) - \sigma^j_t(\bar{X}_t, \bar{u}_t) \right|^{2k} \right)^\frac{1}{2k} dt \right)^{2k} \right]^{2k}
\]

\[
\leq K \varepsilon^{2k} + \varepsilon^k \leq K \varepsilon^k,
\]

thanks to the polynomial growth of the coefficients and the boundedness of the integration interval \( E_\varepsilon \). Indeed, remember that it is easy to control all the moments of \( \bar{X} \) up to a fixed time. In this case the discount factor \( \rho_1 \) can be chosen equal to the initial one \( \rho_1 = r \).

(ii) Using again the global monotonicity assumption and Lemma 1 the estimate for \( y_\varepsilon \) follows in the same way.

(iii) For \( z^\varepsilon \) we start by estimating its norm in the space \( L_{E_x}^{2k, -r\alpha}(\mathbb{R}_+; \mathbb{R}^n) \), for a generic \( \alpha \in \mathbb{R} \).
Using the same technique as in Lemma \[\ref{lem:79}\] we obtain
\[
\sup_{t \in \mathbb{R}_+} e^{-rkt} E |z_t^\varepsilon|^{2k} \leq K \left[ \int_{0}^{\infty} e^{-rkt} \left( E|\delta b_t X_{t} E_{t}(t) + \frac{1}{2} D_x^2 b(\bar{X}_t, \bar{u}_t)(y_t^{\varepsilon})^2 |^{2k} \right) \frac{1}{\varepsilon^k} \frac{1}{\mathbb{I}} dt \right]^{2k} + K \sum_{j=1}^{2} \left[ \int_{0}^{\infty} e^{-rj} \left( E|\delta (D_x \sigma_j^\varepsilon) X_{t} E_{t}(t) y_t^\varepsilon + \frac{1}{2} D_x^2 \sigma_j^\varepsilon(\bar{X}_t, \bar{u}_t)(y_t^{\varepsilon})^2 |^{2k} \right) \frac{1}{\varepsilon^{km}} \frac{1}{\mathbb{I}} dt \right]^{2k}.
\]

The first term (with \(\delta b_t\)) can be treated as before, thanks to the boundedness of \(E_{\varepsilon}\). Let us discuss the second one. It holds
\[
\int_{0}^{\infty} e^{-rkt} \left( E|D_x^2 b(\bar{X}_t, \bar{u}_t) + (y_t^{\varepsilon})^2 |^{2k} \right) \frac{1}{\varepsilon^k} \frac{1}{\mathbb{I}} dt
\]
\[
\leq \int_{0}^{\infty} \left( e^{-rkt} E|D_x^2 b(\bar{X}_t, \bar{u}_t) |^{2k} \right) \frac{1}{\varepsilon^k} \frac{1}{\mathbb{I}} dt
\]
\[
\leq \left( \sup_{t \geq 0} e^{-rkt} E|y_t^{\varepsilon} |^{8k} \right) \frac{1}{\varepsilon^k} \frac{1}{\mathbb{I}} \int_{0}^{\infty} e^{-rkt} \left( E|D_x^2 b(\bar{X}_t, \bar{u}_t) |^{4k} \right) \frac{1}{\varepsilon^k} \frac{1}{\mathbb{I}} dt
\]
\[
\leq K \left( \sup_{t \geq 0} e^{-rkt} E|y_t^{\varepsilon} |^{8k} \right) \frac{1}{\varepsilon^k} \frac{1}{\mathbb{I}} \left[ \int_{0}^{\infty} e^{-rkt} dt + \int_{0}^{\infty} e^{-rkt} \left( E|\bar{X}_t |^{4k(2m+1)} \right) \frac{1}{\varepsilon^k} \frac{1}{\mathbb{I}} dt \right]
\]
\[
\leq K \left( \sup_{t \geq 0} e^{-rkt} E|y_t^{\varepsilon} |^{8k} \right) \frac{1}{\varepsilon^k} \frac{1}{\mathbb{I}} \left[ \int_{0}^{\infty} e^{-rkt} dt + \int_{0}^{\infty} e^{-rkt} E|\bar{X}_t |^{4k(2m+1)} dt \right],
\]
where we used the polynomial growth of \(D_x^2 b\) and Jensen inequality, assuming that \(\int_{0}^{\infty} e^{-rkt} dt < \infty\), hence \(r > 0\). Moreover, if we choose \(\alpha \geq \max(4, 88k(2m+1)) = 8k(2m+1)\), we have that
\[
\int_{0}^{\infty} e^{-rkt} \left( E|D_x^2 b(\bar{X}_t, \bar{u}_t) + (y_t^{\varepsilon})^2 |^{2k} \right) \frac{1}{\varepsilon^k} \frac{1}{\mathbb{I}} dt \leq K \varepsilon,
\]
where \(K = K(r, k, m)\) depends on the choice of the initial discount factor, the order of integration and the polynomial growth of the coefficients of the state. Let us briefly sketch also the computations for the last addendum
\[
\int_{0}^{\infty} e^{-rkt} \left( E|D_x^2 \sigma_j^\varepsilon(\bar{X}_t, \bar{u}_t)(y_t^{\varepsilon})^2 |^{2k} \right) \frac{1}{\varepsilon^k} \frac{1}{\mathbb{I}} dt
\]
\[
\leq K \left( \sup_{t \geq 0} e^{-rkt} E|y_t^{\varepsilon} |^{8k} \right) \frac{1}{\varepsilon^k} \frac{1}{\mathbb{I}} \int_{0}^{\infty} e^{-rkt} \left( E|D_x^2 \sigma_j^\varepsilon(\bar{X}_t, \bar{u}_t) |^{4k} \right) \frac{1}{\varepsilon^k} \frac{1}{\mathbb{I}} dt
\]
\[
\leq K \left( \sup_{t \geq 0} e^{-rkt} E|y_t^{\varepsilon} |^{8k} \right) \frac{1}{\varepsilon^k} \frac{1}{\mathbb{I}} \int_{0}^{\infty} e^{-rkt} \left( E|1 + |\bar{X}_t |^{4k} \right) \frac{1}{\varepsilon^k} \frac{1}{\mathbb{I}} dt.
\]
If \(\alpha \geq 4km\), following the same strategy as above we end up with
\[
\int_{0}^{\infty} e^{-rkt} \left( E|D_x^2 \sigma_j^\varepsilon(\bar{X}_t, \bar{u}_t)(y_t^{\varepsilon})^2 |^{2k} \right) \frac{1}{\varepsilon^k} \frac{1}{\mathbb{I}} dt \leq K \varepsilon^2.
\]
Summing up all the estimates and using Lemma \[\ref{lem:79}\] we easily get the required result, for some \(\rho_3\) big enough. In this case it is sufficient to choose \(\rho_3 \geq \alpha r \geq 8k(2m+1)r\).

(iv) Following Yong and Zhou [24], it is easy to see that
\[
dy_t^\varepsilon = [D_x b(\bar{X}_t, \bar{u}_t) y_t^\varepsilon + A_t^\varepsilon] dt + \sum_{j=1}^{d} \left[ D_x \sigma_j(\bar{X}_t, \bar{u}_t) y_t^\varepsilon + B_t^{j,\varepsilon} \right] dW_t^j,
\]
where
\[
A_t^\varepsilon := \delta b_t X_{E_{t}}(t) + [G_t(t) - D_x b(\bar{X}_t, \bar{u}_t)] \xi_t^\varepsilon;
\]
\[
B_t^{j,\varepsilon} := (G_t^j(t) - D_x^j \sigma(\bar{X}_t, \bar{u}_t)) \xi_t^\varepsilon.
\]
Let us consider $A^\varepsilon(\cdot)$ first.

$$
\int_0^\infty e^{-\frac{r}{4}t} \left( E|A_1|^2k \right) \frac{dt}{t^\frac{1}{2}} \\
\leq K \int_0^\infty e^{-\frac{r}{4}t} \left( E|\delta b x(t)|^2k \right) \frac{dt}{t^\frac{1}{2}} \\
+ K \int_0^\infty e^{-\frac{r}{4}t} \left( E|\{G(t) - D_x b(\tilde{X}_t, \tilde{u}_t)\}|^2k \right) \frac{dt}{t^\frac{1}{2}} \\
\leq K\varepsilon + K \left( \sup_{t \geq 0} e^{-r_0 t} E|\xi_{t, \varepsilon}|^4k \right)^\frac{1}{4} \int_0^\infty e^{-\frac{r}{4}t} \left( E|G(t) - D_x b(\tilde{X}_t, \tilde{u}_t)|^4k \right) \frac{dt}{t^\frac{1}{2}}.
$$
due to the previous result with $\alpha \geq 2$, and Hölder inequality. Regarding the last term we have

$$
G(t) - D_x b(\tilde{X}_t, \tilde{u}_t) = \int_0^1 \left[ D_x b(\tilde{X}_t + \theta \xi_{t, \varepsilon}, u_{\varepsilon}) - D_x b(\tilde{X}_t, \tilde{u}_t) \right] d\theta \\
= \int_0^1 \left[ D_x b(\tilde{X}_t + \theta \xi_{t, \varepsilon}, u_{\varepsilon}) - D_x b(\tilde{X}_t + \theta \xi_{t, \varepsilon}, \tilde{u}_t) \right] d\theta \\
+ \int_0^1 \left[ D_x b(\tilde{X}_t + \theta \xi_{t, \varepsilon}, \tilde{u}_t) - D_x b(\tilde{X}_t, \tilde{u}_t) \right] d\theta.
$$

Hence, using the Taylor expansion with Lagrange rest, there exists $\tilde{x}$ (depending on $t$ and $\omega$) such that

$$
\int_0^\infty e^{-\frac{r}{4}t} |G(t) - D_x b(\tilde{X}_t, \tilde{u}_t)| L^4(\Omega) dt \\
\leq \int_{E_{\varepsilon}} e^{-\frac{r}{4}t} \left( E \left| \int_0^1 D_x b(\tilde{X}_t + \theta \xi_{t, \varepsilon}, u_{\varepsilon}) - D_x b(\tilde{X}_t + \theta \xi_{t, \varepsilon}, \tilde{u}_t) \right|^4k \frac{dt}{t^\frac{1}{2}} \right) \\
+ \int_0^\infty e^{-\frac{r}{4}t} \left( E \left| \int_0^1 D_x^2 b(\tilde{x}, \tilde{u}_t) \theta \xi_{t, \varepsilon}(t) dt \right|^4k \frac{dt}{t^\frac{1}{2}} \right) \\
\leq K\varepsilon + \left( \sup_{t \geq 0} e^{-r_0 t} E|\xi_{t, \varepsilon}|^8k \right)^\frac{1}{4} \int_0^\infty e^{-\frac{r}{4}t} \left( E|D_x^2 b(\tilde{x}, \tilde{u}_t)|^8k \right) \frac{dt}{t^\frac{1}{2}} \\
\leq K(\varepsilon + \varepsilon^{1/2}),
$$
thanks to the estimate obtained in point (i) and the polynomial growth of $D_x^2 b$ (here we have to require $\alpha \geq 32k(2m + 1)$). Then

$$
\int_0^\infty e^{-\frac{r}{4}t} \left( E|A_1|^2k \right) \frac{dt}{t^\frac{1}{2}} \leq K\varepsilon + K\varepsilon^{1/2} \int_0^\infty e^{-\frac{r}{4}t} \left( E|G(t) - D_x b(\tilde{X}_t, \tilde{u}_t)|^4k \right) \frac{dt}{t^\frac{1}{2}} \\
\leq K\varepsilon.
$$

For $B_1^{j, \varepsilon}$, proceeding in a similar way we obtain

$$
\int_0^\infty e^{-\varepsilon t} \left( E|G_0^j(t) - D_x \sigma^j(\tilde{X}_t, \tilde{u}_t)|^4k \right) \frac{dt}{t^\frac{1}{2}} \leq K\varepsilon.
$$

To conclude, we apply Lemma 1 to get

$$
\sup_{t \in \mathbb{R}_+} e^{-r_0 t} E|\eta_{t, \varepsilon}|^2k \leq K \left( \int_0^\infty e^{-\frac{r}{4}t} \left( E|A_1|^2k \right) \frac{dt}{t^\frac{1}{2}} \right)^2k + K \sum_{j=1}^d \left( \int_0^\infty e^{-\varepsilon t} \left( E|B_1^{j, \varepsilon}|^2k \right) \frac{dt}{t^\frac{1}{2}} \right)^k \\
\leq K(\varepsilon^{2k} + \varepsilon^2k) = O(\varepsilon^{2k}).
$$

In this case $\rho_4$ can be chosen as $\rho_4 \geq \rho a \geq 32k(2m + 1)r$. 
(v) Let us denote $d\zeta^c(t) = d(\eta^c(t) - \xi^c(t))$, 
\[
\begin{aligned}
  d\zeta^c &= (D_x b(\bar{X}_t, \eta^c_t)) + A_t^c dt + \sum_{j=1}^d (D_x \sigma_j(\bar{X}_t, \eta^c_t)) dW^j_t, \\
  \zeta^c(0) &= 0,
\end{aligned}
\]
where
\[
A_t^c := \delta D_x b_{\delta E}(t)\xi_t^c + \frac{1}{2} [\tilde{G}_0(t) - D_x^2 b(\bar{X}_t, \eta^c_t)](\xi_t^c)^2 \\
&+ \frac{1}{2} [\tilde{G}_0(t) - D_x^2 b(\bar{X}_t, \eta^c_t)](\xi_t^c)^2 + \frac{1}{2} D_x^2 b(\bar{X}_t, \eta^c_t)[((\xi_t^c)^2 - (\eta_t^c)^2)],
\]
\[
B_t^c := \delta D_x \sigma(t) \xi_t^c + \frac{1}{2} [\tilde{G}_0(t) - D_x^2 \sigma(\bar{X}_t, \eta^c_t)](\xi_t^c)^2 \\
&+ \frac{1}{2} D_x^2 \sigma(\bar{X}_t, \eta^c_t)[((\xi_t^c)^2 - (\eta_t^c)^2)],
\]
and
\[
\begin{aligned}
\tilde{G}_0(t) := 2 \int_0^t \theta D_x^2 b(\theta \bar{X}_t + (1 - \theta)X_t^c, \eta^c_t) d\theta, \\
G_0(t) := 2 \int_0^t \theta D_x^2 \sigma(\theta \bar{X}_t + (1 - \theta)X_t^c, \eta^c_t) d\theta.
\end{aligned}
\]

First, let us consider the $A^c(\cdot)$ term. Applying the Hölder inequality gives
\[
\begin{aligned}
  \int_0^\infty e^{-\frac{\alpha}{2} t} (\mathbb{E}\left| A_t^c \right|^{2k})^{\frac{1}{2k}} dt &\leq \int_0^\infty e^{-\frac{\alpha}{2} t} \left[ (\mathbb{E}|\delta D_x b_{\delta E}(t)\xi_t^c|^{2k})^{\frac{1}{2k}} + \frac{1}{2} (\mathbb{E}|\tilde{G}_0(t) - D_x^2 b(\bar{X}_t, \eta^c_t))|^{2k})^{\frac{1}{2k}}dt \\
  &+ \frac{1}{2} (\mathbb{E}|\tilde{G}_0(t) - D_x^2 b(\bar{X}_t, \eta^c_t))|^{2k})^{\frac{1}{2k}} \\
  &\leq K (\sup_{t \geq 0} e^{-\alpha k t})^{\frac{1}{4k}} \int_0^\infty e^{-\frac{\alpha}{2} t} (\mathbb{E}|\tilde{G}_0(t) - D_x^2 b(\bar{X}_t, \eta^c_t))|^{4k})^{\frac{1}{4k}} dt \\
  &+ K (\sup_{t \geq 0} e^{-\alpha k t})^{\frac{1}{4k}} \int_0^\infty e^{-\frac{\alpha}{2} t} (\mathbb{E}|D_x^2 b_{\delta E}|^{4k})^{\frac{1}{4k}} dt \\
  &+ K (\sup_{t \geq 0} e^{-\alpha k t})^{\frac{1}{4k}} (\sup_{t \geq 0} e^{-\alpha k t})^{\frac{1}{4k}} \int_0^\infty e^{-\frac{\alpha}{2} t} (\mathbb{E}|D_x^2 b(\bar{X}_t, \eta^c_t)|^{4k})^{\frac{1}{4k}} dt.
\end{aligned}
\]
If $\alpha \geq 4$ the first and the third term can be easily controlled. For the last addendum we use the same technique as in (iii) to get the boundedness of the integral for $\alpha \geq 8k(2m + 1)$, hence
\[
\int_0^\infty e^{-\frac{\alpha}{2} t} (\mathbb{E}|A_t^c|^{2k})^{\frac{1}{2k}} dt \leq K \left[ e^{3/2} + e \int_0^\infty e^{-\frac{\alpha}{2} t} (\mathbb{E}|\tilde{G}_0(t) - D_x^2 b(\bar{X}_t, \eta^c_t))|^{4k})^{\frac{1}{4k}} dt + e^2 + e^{3/2} \right].
\]
Finally, we can rewrite $\mathbb{E}|\tilde{G}_0(t) - D_x^2 b(t, \bar{X}(t), u^c(t))|^{4k}$ in the following form
\[
\tilde{G}_0(t) - D_x^2 b(\bar{X}_t, \eta^c_t) =
\begin{aligned}
  &= 2 \int_0^1 \theta D_x^2 b(\theta \bar{X}_t + (1 - \theta)\bar{X}_t, \eta^c_t) d\theta - D_x^2 b(\bar{X}_t, \eta^c_t) \\
  &= 2 \int_0^1 \theta \left[ D_x^2 b(\theta \bar{X}_t + (1 - \theta)\bar{X}_t, \eta^c_t) - D_x^2 b(\bar{X}_t, \eta^c_t) \right] d\theta.
\end{aligned}
\]
If $\alpha \geq 8k(2m + 1)$, by the continuity of the map $x \mapsto D_x^2 b(x, u)$ and dominated convergence theorem it follows that
\[
\int_0^\infty e^{-\frac{\alpha}{2} t} \left( \int_0^1 \theta \left[ D_x^2 b(\theta \bar{X}_t + (1 - \theta)\bar{X}_t, \eta^c_t) - D_x^2 b(\bar{X}_t, \eta^c_t) \right] d\theta \right)^{\frac{1}{4k}} dt \to 0,
\]
as $\varepsilon \to 0$. Then

$$\int_0^\infty e^{-\frac{x^2}{2}} \left( \|A^2\|^{2k} \right)^{\frac{1}{2k}} dt \leq K[\varepsilon^{3/2} + \varepsilon^{3/2}] + o(\varepsilon) = o(\varepsilon).$$

For $B^\varepsilon(t)$ we proceed in the same way to obtain

$$\int_0^\infty e^{-\frac{x^2}{2}} \left( \|B^2\|^{2k} \right)^{\frac{1}{2k}} dt = o(\varepsilon^2).$$

Using Lemma [1], the desired result follows for $\rho_0 \geq \rho_0 \geq 8k(2m + 1)r$. □

10.2. Proof of Proposition [3]

Proof. Since $Y^\varepsilon_t = y^\varepsilon_t(y^\varepsilon_t)^T$, the existence and uniqueness of a solution follow from the existence and uniqueness of the process $y^\varepsilon$ (see Theorem [2]), with the restriction $r > 2c_1/2$.

Let us now denote $A_t := D_x b(X_t, \bar{u}_t), B^j_t := D_x \sigma^j(X_t, \bar{u}_t)$ and note that a symmetric (positive) definite matrix $Y^\varepsilon_t$ can be decomposed as $Y^\varepsilon_t = \sum_{i=1}^n \gamma_i c_i c_i^T$, where $\gamma_i \geq 0$ for all $i$ and $(c_i)_i$ is an orthonormal basis of $\mathbb{R}^n$. Clearly, each $\gamma_i$ and $c_i$ depend both on $t$ and $\varepsilon$ but we omit this notation in the proof.

Having in mind the above, one arrives at

$$\langle A^2 Y^\varepsilon_t, Y^\varepsilon_t \rangle_2 = \text{Tr} \left\{ A^2 Y^\varepsilon_t (Y^\varepsilon_t)^T \right\} = \sum_{i=1}^n \gamma_i^2 \text{Tr} \left\{ A c_i c_i^T c_i c_i^T \right\} = \sum_{i=1}^n \gamma_i^2 \text{Tr} \left\{ c_i c_i^T A c_i c_i^T \right\}$$

and

$$\langle B^j_t Y^\varepsilon_t (B^j_t)^T, Y^\varepsilon_t \rangle_2 = \text{Tr} \left\{ B^j_t Y^\varepsilon_t (B^j_t)^T (Y^\varepsilon_t)^T \right\} = \sum_{i=1}^n \gamma_i^2 \text{Tr} \left\{ B^j_t c_i (c_i^T (B^j_t)^T c_i)^T \right\}$$

and

$$\|B^j_t Y^\varepsilon_t\|^2_2 = \text{Tr} \left\{ B^j_t Y^\varepsilon_t (B^j_t)^T \right\} = \sum_{i=1}^n \gamma_i^2 \text{Tr} \left\{ B^j_t c_i (B^j_t)^T B^j_t c_i^T \right\} = \sum_{i=1}^n \gamma_i^2 \|B^j_t c_i\|^2.$$

where we have used the basic properties of the Trace. Using these estimates we are able to prove the following dissipativity condition

$$\langle A^2 Y^\varepsilon_t + Y^\varepsilon_t A^T_t, Y^\varepsilon_t \rangle + \sum_{j=1}^d \langle B^j_t Y^\varepsilon_t (B^j_t)^T, Y^\varepsilon_t \rangle + \sum_{j=1}^d \|B^j_t Y^\varepsilon_t + Y^\varepsilon_t B^j_t\|^2_2$$

$$\leq 2 \sum_{i=1}^n \gamma_i^2 \langle A c_i, c_i \rangle + \sum_{j=1}^d \sum_{i=1}^n \gamma_i^2 \|B^j_t c_i\|^2 + 2 \sum_{j=1}^d \sum_{i=1}^n \gamma_i^2 \|B^j_t c_i\|^2$$

$$\leq 2 \sum_{i=1}^n \gamma_i^2 \left( \langle A c_i, c_i \rangle + \frac{d}{2} \sum_{j=1}^d \|B^j_t c_i\|^2 \right)$$

$$\leq 2 c_3/2 \sum_{i=1}^n \gamma_i^2 \|c_i\|^2 = 2 c_3/2 \|Y^\varepsilon_t\|^2_2.$$
Now, applying the Itô formula to $e^{-rt}\|Y^\varepsilon_t\|_2^2$ we obtain, for every $T > 0$ and $\delta > 0$

$$
E\left[ e^{-rt}\|Y^\varepsilon_t\|_2^2 \right] + r E \int_0^T e^{-rt}\|Y^\varepsilon_t\|_2^2 dt = 2E \int_0^T e^{-rt} \left[ \langle Y^\varepsilon_t, A_t Y^\varepsilon_t + Y^\varepsilon_t A_t^T \rangle + \sum_{j=1}^d \langle Y^\varepsilon_t, B^j_t Y^\varepsilon_t (B^j_t)^T \rangle \right] dt
$$

$$
+ 2E \int_0^T e^{-rt} \langle Y^\varepsilon_t, \Gamma_t \rangle dt + \sum_{j=1}^d \mathbb{E} \int_0^T e^{-rt}\|B^j_t Y^\varepsilon_t + Y^\varepsilon_t B^j_t + \Lambda^j_t\|_2^2 dt
$$

$$
\leq 2c_{3/2} \mathbb{E} \int_0^T e^{-rt}\|Y^\varepsilon_t\|_2^2 dt + \delta \mathbb{E} \int_0^T e^{-rt}\|Y^\varepsilon_t\|_2^2 dt
$$

$$
+ \frac{1}{\delta} \mathbb{E} \int_0^T e^{-rt}\|\Gamma_t\|_2^2 dt + \sum_{j=1}^d \mathbb{E} \int_0^T e^{-rt}\|\Lambda^j_t\|_2^2 dt.
$$

Hence

$$(r - 2c_{3/2} - \delta) \mathbb{E} \int_0^T e^{-rt}\|Y^\varepsilon_t\|_2^2 dt \leq \frac{1}{\delta} \mathbb{E} \int_0^T e^{-rt}\|\Gamma_t\|_2^2 dt + \sum_{j=1}^d \mathbb{E} \int_0^T e^{-rt}\|\Lambda^j_t\|_2^2 dt,$$

and the estimate follows for $r > 2c_{3/2}$ by sending $T \to +\infty$. The final estimate holds for $r > 2 \max\{c_{1/2}, c_{3/2}\}$. 

10.3. Proof of Proposition 7.

Proof. If we compute the Itô differential of the processes $e^{-rt}\langle y^\varepsilon_t, p_t \rangle$, where $p_t$ is the solution to the finite horizon equation (37), we obtain

$$
d\left( e^{-rt}\langle y^\varepsilon_t, p_t \rangle \right) = \langle d(e^{-rt} y^\varepsilon_t), p_t \rangle + e^{-rt}\langle y_t, dp_t \rangle + \sum_{j=1}^d \langle q^j_t, D_x \sigma^j(X_t, \bar{u}_t) y^\varepsilon_t + \delta \sigma^j(X_t, \bar{u}_t) \rangle dt
$$

$$
- r e^{-rt}\langle y^\varepsilon_t, p_t \rangle + e^{-rt}\langle D_x b(X_t, \bar{u}_t) y^\varepsilon_t, p_t \rangle - e^{-rt}\langle y^\varepsilon_t, D_x b(X_t, \bar{u}_t)^T y^\varepsilon_t \rangle
$$

$$
- \sum_{j=1}^d e^{-rt}\langle y^\varepsilon_t, D_x \sigma^j(X_t, \bar{u}_t)^T q^j_t \rangle + e^{-rt}\langle y^\varepsilon_t, D_x f(X_t, \bar{u}_t) \rangle + r e^{-rt}\langle y^\varepsilon_t, p_t \rangle
$$

$$
+ \sum_{j=1}^d \langle q^j_t, D_x \sigma^j(X_t, \bar{u}_t) y^\varepsilon_t + \delta \sigma^j(X_t, \bar{u}_t) \rangle dt + M_t dW_t,
$$

where the stochastic term is a local martingale with zero mean value (which can be proved by standard localization argument). Hence, by taking expectation we have for all $T > 0$

$$
e^{-rt}E\langle y^\varepsilon_T, p_T \rangle - E \int_0^T e^{-rt} \langle y^\varepsilon_t, D_x f(X_t, \bar{u}_t) \rangle dt = \sum_{j=1}^d E \int_0^T e^{-rt} \langle q^j_t, \delta \sigma^j(X_t, \bar{u}_t) \rangle dt,
$$

thanks to the fact that $\langle y^\varepsilon_0, p_0 \rangle = 0$. Since $(p_t)_{t \geq 0} \in L^2_{\mathbb{F}}(\mathbb{R}^d; \mathbb{R}^n)$ then there exists a sequence of times $(T_n)_{n \geq 1}$ with $T_n \to +\infty$ as $n \to +\infty$ such that along this sequence $E\left[ e^{-T_n} p_{T_n} \right] \to 0$. Hence, for all $n \in \mathbb{N}$ we have that

$$
E\langle e^{-T_n} y^\varepsilon_{T_n}, p_{T_n} \rangle - E \int_0^{T_n} e^{-rt} \langle y^\varepsilon_t, D_x f(X_t, \bar{u}_t) \rangle dt = \sum_{j=1}^d E \int_0^{T_n} e^{-rt} \langle q^j_t, \delta \sigma^j(X_t, \bar{u}_t) \rangle dt.
$$

Thanks to the growth assumptions on $\sigma, f$ and to the regularity of $y^\varepsilon_t$ and $q_t$, we can send $T_n$ to infinity to end with

$$
E \int_0^\infty e^{-rt} \langle y^\varepsilon_t, D_x f(X_t, \bar{u}_t) \rangle dt = - \sum_{j=1}^d E \int_0^\infty e^{-rt} \langle q^j_t, \delta \sigma^j(X_t, \bar{u}_t) \rangle dt.
$$

(82)
Repeating the same argument for $e^{-rt}(z^*_t, p_t)$ we get
\[
\begin{align*}
\mathbb{E} \int_0^T e^{-rt}(z^*_t, p_t) \, dt &= \mathbb{E} \int_0^T e^{-rt}(\delta b(\bar{X}_t, \bar{u}_t) + \frac{1}{2} \mathbb{E} \left[ D_x^2 \sigma^j(\bar{y}^i_t)^2 \right]) \, dt \\
&\quad + \frac{1}{2} \sum_{j=1}^d \mathbb{E} \int_0^T e^{-rt}(D_x \sigma^j(\bar{X}_t, \bar{u}_t)(\bar{y}^i_t)^2, q_t) \, dt + o(\varepsilon).
\end{align*}
\]
where the stochastic term is a local martingale with zero mean value (which can be proved by the same argument as before). Hence, taking expectation we obtain for all $T > 0$
\[
-\mathbb{E} \int_0^T e^{-rt}(z^*_t, D_x f(\bar{X}_t, \bar{u}_t)) \, dt = \mathbb{E} \int_0^T e^{-rt}(\delta b(\bar{X}_t, \bar{u}_t) + \frac{1}{2} \mathbb{E} \left[ D_x^2 \sigma^j(\bar{y}^i_t)^2 \right]) \, dt \\
&\quad + \frac{1}{2} \sum_{j=1}^d \mathbb{E} \int_0^T e^{-rt}(D_x \sigma^j(\bar{X}_t, \bar{u}_t)(\bar{y}^i_t)^2, q_t) \, dt + o(\varepsilon).
\]
The term $o(\varepsilon)$ comes from the following estimate
\[
\left| \mathbb{E} \int_0^\infty e^{-rt}(\delta D_x \sigma^j(\bar{X}_t, \bar{u}_t)y^i_t, q^j_t) \, dt \right|
\]
\[
\leq \mathbb{E} \int_{E_\varepsilon} e^{-rt}(1 + |\bar{X}_t|^m)|y^i_t||q^j_t| \, dt
\]
\[
\leq C \sup_{t \in E_\varepsilon} \mathbb{E} \left[ e^{-rt}(1 + |\bar{X}_t|^m)|y^i_t|^2 \right]^{1/4} \left( \mathbb{E} e^{-rt}|q^j_t|^2 \right)^{1/2} \, dt
\]
\[
\leq C \varepsilon \left( \int_{E_\varepsilon} \mathbb{E} e^{-rt}|q^j_t|^2 \, dt \right)^{1/2},
\]
and the last integral goes to zero as $\varepsilon$ goes to zero, since $\mathbb{E} \int_0^\infty e^{-rt}|q^j_t|^2 \, dt < \infty$. Applying the same strategy as before we can choose a sequence $(T_n)_{n \geq 1}$ with $T_n \to +\infty$ as $n \to +\infty$ such that along this sequence $\mathbb{E} [e^{-T_n \mathbb{E}(P_{T_n})}] \to 0$. This way we end up with
\[
-\mathbb{E} \int_0^\infty e^{-rt}(z^*_t, D_x f(\bar{X}_t, \bar{u}_t)) \, dt
\]
\[
= \mathbb{E} \int_0^\infty e^{-rt}(\delta b(\bar{X}_t, \bar{u}_t) + \frac{1}{2} \mathbb{E} \left[ D_x^2 \sigma^j(\bar{y}^i_t)^2 \right], p_t) \, dt \\
&\quad + \frac{1}{2} \sum_{j=1}^d \mathbb{E} \int_0^\infty e^{-rt}(D_x \sigma^j(\bar{X}_t, \bar{u}_t)(\bar{y}^i_t)^2, q_t) \, dt + o(\varepsilon).
\]
(83)
If we substitute relations (S2) and (S3) into equation (53), we obtain

\[
J(u^*(\cdot)) - J(\bar{u}(\cdot)) = E \int_0^\infty e^{-rt} \left[ -\sum_{j=1}^d \langle q^j, \delta \sigma^j(X_t, \bar{u}_t) \rangle - \langle p_t, \delta b(X_t, \bar{u}_t) \rangle + \delta f(X_t, \bar{u}_t) \right] dt + \frac{1}{2} E \int_0^\infty e^{-rt} \left[ -\sum_{j=1}^d \langle D^2_x \sigma^j(X_t, \bar{u}_t)(y^j_t)^2, q_t \rangle - \langle D^2_x b(X_t, \bar{u}_t)(y^j_t)^2, p_t \rangle + \langle D^2_x f(X_t, \bar{u}_t), y_t \rangle \right] dt + o(\varepsilon),
\]

and recalling the definition of the Hamiltonian \(H(x, u, p, q) = \langle p, b(x, u) \rangle + \text{Tr} [q^T \sigma(x, u)] - f(x, u)\) we have the desired result. \(\square\)

10.4. **Conditions on the discount factor** \(r\). Here we collect some restrictions on the discount factor used throughout the computations in the paper. For the purposes of the SMP it is not necessary to find precise values of the discount factor, in general \(r\) has to be positive and big enough. Nevertheless, it can be useful to exhibit some sufficient conditions.

Starting from the well posedness of the state equation, we have to require \(r > 2c_1/2\) in order to find a unique solution in the space \(L^{2,-r}_F(\mathbb{R}^n; \mathbb{R}^n)\). Regarding the first variation equation we have no other restriction. On the contrary, to assure that \(D^2_x b(X_t, \bar{u}_t)(y^j_t)^2 \in L^{2,-r}(\mathbb{R}^n; \mathbb{R}^n)\) in the equation for \(z^\varepsilon\), a sufficient condition is

\[
r > 2 \max \{0, c_{1/2}, c_{2(m+1)-1}, c_{2m-1}, c_3\}\]

where \(c_3\) comes from estimate (15) applied to the process \(y^\varepsilon\). Further restrictions come from the proof of Proposition 1. Here it follows that one can choose \(\rho_1, \rho_2 \geq 2c_{1/2}; \rho_3, \rho_5 \geq 16k(2m + 1) \max\{c_{2k(2m+1)-1}, c_{4k-1}, c_{2km-1}\}\) and \(\rho_4 \geq 64k(2m + 1) \max\{c_{4k(2m+1)-1}, c_{4km-1}\}\). These conditions are derived from the polynomial growth assumptions and from the use of the Hölder inequality.

The choice of the discount factor \(r\) for the first adjoint equation (see Theorem 3) depends on the a priori estimate given by Lemma 3 as well as the integrability of the forcing term \(D_x f(X_t, \bar{u}_t)\). Therefore, due to the polynomial growth, it is easy to see that it is sufficient to consider \(r > 2 \max\{0, c_{1/2}, c_{q-1}\}\).

For the existence and uniqueness of \((y^\varepsilon_{ts})\), we choose \(r > 2c_{1/2}\). Regarding the estimates (57) and (S2), it is sufficient to choose \(r > 2 \max\{c_{1/2}, c_3\}\). Now, for the existence of the process \(P\), it is sufficient to take \(r > 2 \max\{0, c_5, c_{3(2m+1)-1}, c_{3m-1}, c_{q-1}\}\) (for \(p = \frac{3}{2}, q = 3\) in (S3)). Regarding Proposition 6 we have to add some restrictions originating from Lemma 1 throughout the proof. More precisely, it is sufficient to require \(r > 2 \max\{c_7, c_{2m-1}, c_3\}\).

To conclude, the statement of the SMP holds true if the discount factor is chosen in a way such that all the previous results can be applied. Hence, it is sufficient to choose \(k = 1\) and \(r\) such that

\[
r > 64(2m+1) \max\{0, c_{1/2}, c_3, c_7, c_{1-1}, c_{3l-1}, c_{2m-1}, c_{3m-1}, c_{4m-1}, c_{2(2m+1)-1}, c_{3(2m+1)-1}, c_{4(2m+1)-1}\}.
\]
