GENERAL

Unless stated otherwise, all reactions were carried out under Ar in flame-dried glassware. The solvents used were purified by distillation over the drying agents indicated and were transferred under Ar: THF, Et₂O, 1,4-dioxane (Mg/anthracene), CH₂Cl₂, DME, MeCN (CaH₂), n-pentane, benzene, toluene (Na/K). Flash chromatography on silica gel (FC): Merck silica gel 60 (230–400 mesh).

All commercially available compounds (Fluka, Lancaster, Aldrich) were used as received, unless stated otherwise. Compounds 14,1 15a, S3,2 LiOSi(OtBu)₃,3 were prepared as described in the literature. The molecular sieves used in this investigation were dried for 24 h at 150 °C (sand bath) under vacuum prior to use and were stored and transferred under argon atmosphere.

IR: Spectrum One (Perkin-Elmer) spectrometer, wavenumbers (v) in cm⁻¹.

MS (EI): Finnigan MAT 8200 (70 eV), ESI-MS: ESQ3000 (Bruker), accurate mass determinations: Bruker APEX III FT-MS (7 T magnet) or Mat 95 (Finnigan). Elemental analysis: H. Kolbe, Mülheim/Ruhr.

NMR. Spectra were acquired on Bruker AvanceIII 300, 400, 500 MHz or an AvanceNeo 600 MHz NMR spectrometer in the solvents indicated; chemical shifts (δ) are given in ppm relative to TMS, coupling constants (J) in Hz. The solvent signals were used as references and the chemical shifts converted to the TMS scale (CDCl₃: δC = 77.0 ppm; residual CHCl₃ in CDCl₃: δH = 7.26 ppm; CD₂Cl₂: δC = 53.8 ppm; residual ¹H: δH = 5.32 ppm; [D₆]-toluene: δC = 20.7 ppm; residual D₅C₆CD₂H: δH = 2.09 ppm). Chemical shifts were referenced indirectly to the ¹H chemical shift of the solvent.⁴

Diffusion coefficients were obtained from a double stimulated echo sequence with bipolar gradient pulses, convection compensation, longitudinal eddy current delay (LED) and three spoiler gradients (Bruker sequence: dstebpgp3s). The gradient pulse strength G was incremented from 2% to 98% of the maximum Gₘₐₓ with a squared gradient ramp in 60 steps. The diffusion time (Δ) used was 71 ms and the length of a gradient pulse gradient pulse (δ/2) of the encoding gradient was 1.3 ms. The maximum gradient strength Gₘₐₓ of the NMR probe (PA BBO 400S1 BBF-H-D-05 Z PLUS) was 53.5 G·cm⁻¹. Diffusion coefficients were obtained by averaging three diffusion coefficients obtained from fitting the signal decay of three different resonance integrals to the Stejskal-Tanner equation (I) in the Bruker TOPSPIN T1T2 relaxation module.

\[ I(G) = I_0 e^{-D(\gamma G \delta)^2(\Delta-\delta/3)} \]  

Diffusion values were predicted using an EXCEL spreadsheet Stokes–Einstein Gierer-Wirtz Estimation (SEGWE) method.⁵
**183W NMR Spectroscopy.** 183W NMR shifts were extracted from the indirect dimension of a 1H,183W HMBC experiment. For the measurement, a standard Bruker BBFO probe (31P-119Ag) of a AVIIIHD 400 MHz NMR spectrometer could be tuned to the 183W resonance frequency (16.67 MHz). The standard parameters for the experiment are shown in the following Table:

| PULPROG | F1   | F2 |
|---------|------|----|
| Nuc1    | 1H   | 183W |
| TD      | 2048 | 512 |
| Offset (ppm) | 5  | 500 |
| SW (ppm) | 12.98 | 997.4 |
| CNST13  | 4    |
| DS      | 16   |

The π/2 pulse was calibrated for a solution of Na2WO4 in D2O (1 m) and had a typical length of 35 µs with a pulse power of 85 W. Data points in the indirect dimension (F1) were sparsely sampled with 25% NUS to reduce the measurement time. A second HMBC (10% NUS) with the same offset O2, but different SW in the indirect dimension was acquired to make sure that the observed peak is not folded. Raw data were Fourier-transformed with zero-filling and linear-prediction in the indirect dimension giving to a total matrix size of 1024 x 1024 datapoints. Unless denoted otherwise 1D 183W spectra shown in the manuscript were generated from the 2D spectrum as a sum of all slices that contained a 183W signal. The 1D 183W spectrum of compound 4b was acquired with a standard ineprtd sequence optimized for the same long range coupling (4 Hz) as the HMBC spectra. Data from AvanceNEO 600 MHz NMR spectrometer was acquired Bruker BBO CryoProbe, which significantly reduced the measurement time of most of the spectra, especially the 1D 13C spectrum. A good SNR in the 13C spectra was crucial to extract the 183W-13C coupling constants of the complexes.

Preparation of the Ligands

**CAUTION:** This and other experiments described below require pyrophoric materials (tert-butyllithium) which must be handled and disposed with great care! Likewise, quenching of the reactions can be dangerous. Especially when carried out on large scale, the use of either isopropanol in heptanes (2 mL) or of dry CO₂ as quenching agent is recommended.

(5’-(2-(Diethylsilyl)phenyl)−[1,1’:3,1’’-terphenyl]-2,2”-diyl)bis(diethylsilane) (S1)

A two-necked, round-bottomed flask was equipped with a magnetic stir bar and a gas inlet connected to an argon-vacuum manifold. The flame-dried flask was filled with argon and charged with 1,3,4-tris-2’-bromophenylbenzene (14) ¹ (2.00 g, 3.68 mmol) and Et₂O (77 mL). The resulting mixture was cooled to −125 °C. A solution of tert-butyllithium (14.2 mL, 22.6 mmol, 1.6 M in n-pentane) was added dropwise and the mixture was allowed to warm to ambient temperature. After stirring for 1 h stirring, the mixture was cooled to −125 °C and diethylsilane (2.86 mL, 22.1 mmol) was added dropwise. The mixture was then warmed to ambient temperature and stirring was continued overnight. The reaction was carefully quenched by adding water and the resulting mixture was transferred into a separation funnel. The organic phase was separated and the aqueous solution was washed with sat. NaHCO₃, filtered and concentrated in vacuo.

The combined organic layers were dried over MgSO₄, filtered and concentrated in vacuo. The residue was purified by flash chromatography on silica gel (hexanes/ethyl acetate, 10:1) to give the title compound as a colorless solid (1.9 g, 91%). ¹H NMR (400 MHz, CDCl₃): δ = 7.58 – 7.54 (m, 3H), 7.42 – 7.36 (m, 3H), 7.35 – 7.28 (m, 6H), 7.22 (s, 3H), 4.13 (p, J = 3.4 Hz, 3H), 0.84 (t, J = 7.8 Hz, 18H), 0.60 (m, 12H). ¹³C NMR (101 MHz, CDCl₃): δ = 149.4, 143.1, 136.0, 134.2, 129.6, 129.1, 128.9, 126.4, 8.5, 4.2. Complex [NMe₃]W(CO)₅(COAr) (Ar = 2,6-dimethylphenyl) (S5)⁶

A two-neck round-bottom flask is equipped with a Teflon-coated magnetic stirring bar and an Argon-vacuum manifold. The flask is charged with 2-bromo-1,3-dimethylbenzene (3.02 g, 16.0 mmol) and diethyl ether (67 mL). The solution is cooled to −25°C and a solution of tert-butyllithium (21.0 mL, 33.6 mmol, 1.6 M in n-pentane) was added over 10 min. Once the addition is complete, stirring is continued for 1 h at −20°C.

A 250 mL, three-neck round-bottom flask is equipped with a Teflon-coated magnetic stirring bar, a reflux condenser, a pressure-equalizing dropping funnel fitted with a rubber stopper and an Argon-vacuum manifold. The flask is charged with W(CO)₆ (5.63 g, 16.0 mmol) and diethyl ether (51 mL) and the mixture is cooled to 0°C. The cold (−20 °C) solution of 2,6-dimethylphenyl lithium is added via the dropping funnel over 5 min to the suspension, causing an immediate color change to orange-brown and a slight exotherm.

Once the addition is complete, the resulting orange-brown solution is stirred at ambient temperature for 2 h. The dropping funnel and the reflux condenser are replaced by a glass stopper and the solvent is removed at ambient temperature under reduced pressure. A solution of Me₃NBBr (3.84 g, 24.4 mmol) in deionized water (20 mL) is added to the remaining dark yellow residue, causing the formation of an orange solid. The resulting suspension is vigorously stirred for 15 min at ambient temperature before the precipitate is filtered off in air, washed once with deionized water (5 mL), twice with cold (0 °C) diethyl ether (20 mL) and dried under high vacuum (10⁻³ mbar) to give complex S5 as a pale orange microcrystalline solid (5.45 g, 64%). The complex is still contaminated with starting complex W(CO₆), which can't be removed due to its low solubility, but turned out not to be problematic in the next step.

Complex [W≡CAr]Br₃(dme)] (Ar = 2,6-dimethylphenyl) (S6).

A 250 mL, three-neck round-bottom flask is equipped with a Teflon-coated magnetic stirring bar, a thermometer adapter, a rubber stopper and an Argon-vacuum manifold. The flask is charged with complex S5 (5.82 g, 10.9 mmol) and CH₂Cl₂ (93 mL). The mixture is cooled to −78 °C and stirred for 15 min before a solution of oxalyl bromide (1.03 mL, 11.0 mmol) in CH₂Cl₂ (6 mL) is added dropwise over 10 min. Once the addition is complete, stirring is continued for 15 min at −78 °C. The mixture is then allowed to warm until a rapid color change to light brown is observed (at an internal temperature of ca. −40 °C). At this point, the reaction flask is quickly recooled to −78 °C.

A 1 L, three-neck jacketed cooling flask is equipped with a Teflon-coated magnetic stirring bar, a jacketed cooling filter frit (diameter: 4.5 cm; height: 20 cm; porosity: 4) containing a 3 cm-length pad of Celite®, a 20 mL pressure-equalizing dropping funnel connected to an Argon-vacuum manifold. The Celite® in the jacketed filter is slurried with CH₂Cl₂ and cooled to −78 °C using a cryostat. The 1 L, three-neck jacketed flask is loaded with 1, 2-dimethoxyethane (5.64 mL, 54.3 mmol) and cooled to −78 °C. The cold light
brownish mixture is filtered onto the Celite® packed filter frit, resulting in a bright yellow filtrate. Upon contact with DME in the 1 L receiving flask, a color change from yellow to dark red is observed. The mixture is stirred for 10 min before a solution of Br₂ (0.56 mL, 11.0 mmol) in CH₂Cl₂ (5 mL) is added dropwise over a period of 15 min via the dropping funnel. Once the addition is complete, the mixture is stirred for 15 min. The resulting brown-orange mixture is allowed to reach ambient temperature over the course of 1 h, during which time the color intensifies. Stirring is continued for 1 h at ambient temperature before the dropping funnel and the filter are replaced by glass stoppers. The reaction mixture is filtered through a pad of Celite® and the filtrate is concentrated at ambient temperature under reduced pressure to give complex S6 as a green microcrystalline solid (6.28 g, 92%). ¹H NMR (600 MHz, CD₆₂O): δ = 7.12 (dp, J = 7.7, 0.7 Hz, 2H), 6.15 (t, J = 7.6 Hz, 1H), 3.62 (d, J = 0.8 Hz, 6H), 3.47 (s, 3H), 3.38 (s, 3H), 2.96 – 2.92 (m, 2H), 2.89 – 2.85 (m, 2H). ¹³C NMR (151 MHz, CD₆₂O): δ = 337.4, 150.4, 136.9, 132.1, 125.2, 78.2, 75.5, 69.4, 60.2, 20.6. Equilibration Kinetic Experiments

A flame dried J. Young NMR tube was filled with argon, charged with a stock solution of the complex (3.0 μmol, 0.5 mL, 5.0 μM in [D₈]-toluene, 5 mol%) and a ¹H-NMR spectrum was recorded at 27°C. Then a solution of 1-methoxy-4-(prop-1-yn-1-yl)benzene (100 μL, 60 μmol, 0.6 M in [D₈]-toluene, 1.0 equiv.) was added and the conversion of this substrate to 1,3-bis(4-methoxyphenyl)-2-propa-1,2-diyn and 2-butyne was monitored by ¹H-NMR spectroscopy at 27°C. The data was corrected for relaxation effects as the relaxation time of 2-butyne is significantly longer due to its high symmetry and small size. Therefore two measurements were compared after the reaction: One with the standard data set and one with a longer delay (30s). Correction factor: 1-methoxy-4-(prop-1yn-1-yl)benzene = 1.023; 2-butyne = 1.127; 1,3-bis(4-methoxyphenyl)-2-propa-1,2-diyn = 1.028. Mass balance represents the sum of 2-butyne, 1-methoxy-4-(prop-1yn-1-yl)benzene and 1,3-bis(4-methoxyphenyl)-2-propa-1,2-diyn.

Activation Parameters

Figure S-26. Analysis of the 2D ROESY NMR experiment revealed a chemical exchange of two Cα/Cα' ethyl groups in complex 18.

1H NMR signals of the four protons that are exchanging were simulated and fitted in the DNMR module of Bruker Topspin 4.09 at 5 different temperatures (243K, 253K, 263K, 273K, 283K) to obtain the exchange rate \( k \) between the groups at different temperatures. For the line-shape fitting a four site exchange model was used (H8→H2, H2→H8, H9→H3 and H3→H9). The results are shown in Table S-5.

COMPUTATIONAL DETAILS

All geometry optimizations were performed with the Gaussian09 package\textsuperscript{13} using the PBE0 functional.\textsuperscript{14} W was represented by the quasi-relativistic effective core potential (RECP) from the Stuttgart group and the associated basis sets.\textsuperscript{15-17} The remaining atoms (H, C, O, Si) were represented by a double-\(\zeta\) Def2-SVP basis set.\textsuperscript{18} Geometry optimizations were performed using the GD3 dispersion correction\textsuperscript{19} and the SMD model\textsuperscript{20} to account for the solvent (toluene).

NMR calculations were performed within the GIAO framework using ADF 2014\textsuperscript{21} with the PBE0 functional and Slater-type basis sets of double-\(\zeta\) quality (DZ). Relativistic effects were treated by the 2 component zeroth order regular approximation (ZORA).\textsuperscript{22} Analysis of scalar-relativistic natural localized molecular orbitals were done with the NBO 6.0 program.\textsuperscript{23} Calculated NMR shielding tensors were analyzed using these scalar-relativistic NLMO.\textsuperscript{24,25} The 3D representation of the calculated shielding tensors were obtained as polar plots\textsuperscript{26} of functions \(\sum_i r_i \sigma_i \).
