HCV replication in PBMC and its influence on interferon therapy

Guo-Zhong Gong, Li-Ying Lai, Yong-Fang Jiang, Yan He, Xian-Shi Su

INTRODUCTION

Hepatitis C virus (HCV), a single positive-strand RNA, belongs to the Flaviviridae family, and is the major cause of post-transfusion hepatitis. Infection with HCV usually results in chronic hepatitis, which may progress to cirrhosis and finally to hepatocellular carcinoma. The mechanisms responsible for the chronicity are unclear, one of which is supposed to be that HCV has the ability to escape the host immunity by mutations in genome. There are numerous genotypes of HCV worldwide, and genotype 1b is found to be responsible for the most cases of HCV infection in southern China[1]. IFN has been a widely accepted drug for the treatment of patients with HCV infection for more than 10 years, and now combination of IFN with ribavirin becomes the choice of therapy[2,3]. Reinfecion of HCV after orthotopic liver transplantation has postulated that there exists extrahepatic sites suitable for HCV replication[4]. The possible extrahepatic cells for HCV replication may be PBMC, cells in pancreas, adrenal gland, bone marrow and spleen, even in the cerebrospinal fluid[5-7], among them, PBMCs have been the most controversial, in which the minus strand HCV RNA, a replicative intermediate of HCV, has been found. It still remains unclear whether HCV replication in PBMC is a factor influencing IFN therapy response. In this study, we not only detected the minus strand HCV RNA and HCVNS5 protein expression in PBMC of patients with hepatitis C, but also analyzed the relationship between minus strand HCV RNA in PBMC and IFN response.

MATERIALS AND METHODS

PBMC preparation

Blood samples were collected from 54 patients with hepatitis C virus infection from January of 1994 to January of 1998, all of them are positive for anti-HCV by ELISA (Sino-American Biotech. Company, China) and HCV RNA by RT-PCR (Sino-American Biotech. Company, China). PBMCs were separated from 10 µL of whole blood mixed with sodium citrate by density gradient centrifugation with ficoll-hypaque. The separated PBMCs were washed four times in 10 µL of RPMI-1640 and then frozen and stored at -70°C until use.

Cellular total RNA extraction and RT-PCR

Total RNA of the PBMCs was extracted with an RNA isolation kit (Shanghai Huaxun Company, China) according to the manufacturer’s instructions. Primers P1: 5’- CGGCGGCACTAGGAAAGACTTCC-3’ and P2: 5’- ATGTACCCCCATGCCAACC CGGC-3’ (as the external pair), and P3: 5’ -AGGAAGACTTTCCAGGGCGT-3’ and P4: 5’-GAGCATCCG GCCACCA-3’ (as the internal pair) for RT-PCR were designed according to Okamoto et al[10]. 5 µl of PBMC RNA and 1 µl of P1 (for producing cDNA of minus HCV RNA) or 1 µl of P2 (for producing cDNA of plus HCV RNA) were added to the reverse transcription system (Promega, USA). The reverse transcription system includes 10×buffer 2 µl, 25 mmol/L MgCl2 4 µl, RNasin 1 µl, AMVRT 15 U, 10 mmol/L dNTP 2 µl with a total volume of 20 µl by adding ddH2O. After incubation for 30 min at 42°C, the synthesized HCV RNA cDNA was exposed at 95°C for 30 min to destroy AMVRT. The first PCR was performed with the

RESULTS: HCV plus strand RNA was found in 10 of 19 (52.6 %) acute hepatitis C patients and 22 of 35 (62.9 %) chronic hepatitis C patients. HCV minus strand RNA was detected in 14 of 35 (40.0 %) chronic hepatitis C patients, but only one patient (5.3 %) with acute HCV infection was found to be minus HCV RNA positive. Though no HCV NS5 protein expression was found in the examined 10 cases of acute HCV infection, it was positive in 17 of 20 (85.0 %) chronic hepatitis C patients by indirect immunofluorescence assay. There are significant differences of positive rate of the minus-strand and HCVNS5 protein between acute and chronic hepatitis C groups (u=2.07, P<0.05 and u=4.43, P<0.01 respectively). The patients with minus-strand HCV RNA showed a significantly lower 6-month sustained response (SR-6) to IFN compared to those without minus-strand HCV RNA in PBMCs (biologically 14.3 % vs 42.8 %, χ²=4.12, P<0.05 and virologically 7.1 % vs 23.9 %, χ²=4.24, P<0.05).

CONCLUSION: HCV is capable of infecting and replicating in PBMCs, and HCVNS5 protein was expressed in PBMCs. The patients with minus strand HCV RNA in PBMCs showed a significantly lower 6-month sustained response to IFN, suggesting that minus-strand HCV RNA in PBMCs may be one of the factors influencing response to IFN therapy.

Gong GZ, Lai LY, Jiang YF, He Y, Su XS. HCV replication in PBMC and its influence on interferon therapy. World J Gastroenterol 2003; 9(2): 291-294

above synthesized HCVRNA cDNA as a template. The external primers (P1 and P2) were added into the PCR reaction mix. After pre-denaturing for 5 min, the reaction mix denatured at 94 °C for 60sec, annealed at 55 °C for 60sec and extended at 72 °C for 90sec for 35 cycles. The second PCR was performed same as in the first PCR except the production of the first PCR was used as the template and with the internal primers (P3 and P4). A total volume of 7µl the second PCR product was loaded onto 2 % agarose gel containing 0.5 µg/mL EB. After electrophoresis, the gel was placed under ultraviolet ray to analyze the results (Figure 1).

**Figure 1** Analysis of HCVRNA plus-stand (A) and minus-strand (B). Lane 1, 2, 3, 4, 5: Serum Samples from the patients with hepatitis C. 144bp means plus of minus strand HCVRNA. Lane 6: DNA marker (pGEM-7 HindIII/EcoRI).

**Immunofluorescence assay**

After being separated, PBMCs were suspended (1×10^6 cell·mL^{-1}) in RPMI-1640, dropped on to slides, and air dried. The slides were then fixed in acetone for 20 min at -20 °C, washed with PBS, and air-dried. Mouse anti-human HCV NS5 McAb (1:400, Virostat, U.S.A) was added onto the slides. After 30 min incubation at 37 °C, the slides were washed three times in PBS, and then isothiocyanate-conjugated rabbit anti-mouse IgG was added and incubated for 30 min. Slides were then washed and observed under microscope (Figure 2).

**Figure 2** Indirect immunofluorescent assay for detection of HCVRNA and HCVNS5 protein in PBMCs of patients with hepatitis C, 17/20 (85%) patients with acute hepatitis C and a significant difference was found between these two groups (u=2.07, P<0.05); and virologically (SR-6: 7.1 % vs 23.9 %, $\chi^2=4.24$, P<0.05). Regarding to HCVNS5 expression in PBMCs of patients with hepatitis C, 17 out of 20 patients with chronic hepatitis C were positive, but all the 10 patients with acute hepatitis C were found negative, and there is a remarkable statistically significant difference between the two groups ($u=4.43$, P<0.01).

The influence of HCV RNA status in PBMCs on therapy response to IFN

Six-month regiment with 3MU of IFN-α 2b was completed in 35 patients with chronic hepatitis C, and the biochemical and virological ETR and SR-6 were evaluated. There is a tendency to have a lower response to IFN treatment in the patients with plus-strand HCVRNA positive in PBMCs, although no statistically significant difference was found when compared with the negative group. The patients with minus-strand HCVRNA in PBMCs showed a significantly lower SR-6 to IFN therapy than those without HCVRNA minus-strand, but virologically (SR-6: 7.1 % vs 23.9 %, $\chi^2=4.24$, P<0.05) (Table 2).

**Table 2** The influence of HCVRNA in PBMC on interferon response

| HCVRNA plus strand | HCVRNA minus strand |
|--------------------|---------------------|
| Positive           | Negative            |
| ETR (Biochemical)  | 13 (59.1%)          | 7 (53.7%)          |
| ETR (Virological)  | 11 (50.0%)          | 6 (42.9%)          |
| SR-6 (Biochemical) | 8 (36.7%)           | 6 (46.2%)          |
| SR-6 (Virological) | 6 (27.3%)           | 5 (38.5%)          |

*Comparison of biochemical SR-6 between HCVRNA positive and negative groups, $\chi^2=4.12$, P<0.05; *Comparison of virological SR-6 between HCVRNA positive and negative groups, $\chi^2=4.24$, P<0.05.
DISCUSSION

Extrahepatic HCV replication has long been a controversial topic since the finding of the high rate of re-infection of grafts after orthotopic liver transplantation in the patients with the end-stage HCV induced liver diseases. Weather PBMCs is suitable for HCV replication is still uncertain. The detection of the minus strand HCV RNA is thought to be reasonable for the discovery of HCV replication because the minus strand RNA is the replicative intermediate of HCV. In recent years, several reports on the detection of HCVRNA in PBMCs have been published[12-14]. Cribier et al incubated PBMCs healthy donors with HCV positive sera, and detected HCV RNA plus-strand and minus-strand using RT-PCR and in situ hybridization[15]. Our results showed that HCV RNA plus-strand were common in the PBMCs of patients, in both acute and chronic infection patients. This high rate of plus-strand HCV RNA is usually thought to be resulted from the contamination of plasma, therefore, minus-strand HCV RNA was explored in the PBMCs from hepatitis C patients, which indicates the replication of HCV in PBMCs. In acute HCV infection, HCV RNA minus-strand is rare in PBMCs, but in the chronic group, the minus-strand HCV RNA is not uncommon in the PBMCs (14 of 35, 40.0 %), which is similar to what Chang et al reported[16]. The ratio of HCV RNA minus-strand detected in chronic hepatitis C is much higher than that in acute hepatitis C, suggesting that the replication of HCV in PBMCs may play an important role in the processes of chronicity, and the mechanism could be that HCV in PBMCs can escape from clearance resulting from host immunity, and make the infection of HCV persistent. On the other hand, the dysfunction of the HCV infected PBMCs leads to immune function decline or in disorder, and this becomes more difficult for the host to clear intrahepatic HCV, so that the injure of hepatocytes persists[17]. Although minus-strand HCV RNA is the replicative form and found not in patient’s serum or plasma, indicating that is a more convincing parameter for HCV replication, some authors are still arguing that the minus-strand HCV RNA in the blood cells including PBMC may be artifacts from self-priming or mispriming during PCR reaction[18,19], or contamination or passive absorption by circulating virus[20,21]. To overcome that point, the expression of HCV related proteins in extrahepatic cells has become the key point for the identification of HCV replication. Sansonno et al, found HCV exists and replicates mainly in plasma of PBMCs, and the viral proteins, such as core protein, NS3 were found to be expressed in PBMCs[22]. Chen et al, analyzed the relationship between HCV core expression in PBMCs and the diseased state of hepatitis C patients and found that the core protein was more intensely expressed in the nucleus of PBMCs from advanced chronic hepatitis C patients than that from the moderate patients[23]. We further performed an indirect inmunofluorescent assay for HCVN5S protein and its expression was found mainly in cytoplasm of PBMCs from patients with chronic hepatitis C. Our results indicate that HCV not only replicates but also produces its related protein in PBMCs.

IFN is known to possess both immunomodulatory and antiviral activities. It is tempting to postulate that IFN therapy may enhance the host immune response to promote the clearance of HCV infection. IFN is currently the only approved effective drug for hepatitis C infection, and combined with ribavirin, its antiviral activity will be increased[24-26]. Serum HCV load and the HCV subtypes have been considered as the major factors to influence the response to IFN therapy[27,28]. Others influencing factors include the increased amount of MxA mRNA, the higher complexity of HCV quasispecies and the frequency of mutations in NS5A region[29,30]. The extrahepatic HCV replication, especially in the PBMCs, acts as a predictor for the response to IFN therapy needs to be explored. Omata et al, reported a prospective IFN study, in which most of patients treated with IFN obtained normalization of serum aminotransferase, whereas only 3 cases from the control showed such change (P<0.02); serum hepatitis C virus RNA became undetectable in 10 of 11 treated cases, but in only 1 of 12 patients of control group. IFN prevents the progression of acute hepatitis C to chronicity by eradicating HCV. The response of patients with chronic hepatitis C to IFN treatment was significantly lower than that of patients with acute hepatitis C. That the detection ratio of HCVRNA minus-strand in PBMC of chronic hepatitis C is significantly higher than that of acute hepatitis C suggests that the replication of HCV in PBMCs is an important factor influencing the response to IFN treatment[29]. Löhrl et al, reported that there was no relationship between HCVRNA minus-strand in PBMC and the response to IFN treatment[30]. Others reported that the replication of HCVRNA in PBMC may be the source of relapse after IFN treatment in chronic hepatitis C[31,32]. Our results show that the replication of HCVRNA in PBMC may be the source of relapse after IFN treatment with IFN.
