Abstract

In this brief paper, we study the value function in maximum hands-off control. Maximum hands-off control, also known as sparse control, is the $L^0$-optimal control among the admissible controls. Although the $L^0$ measure is discontinuous and non-convex, we prove that the value function, or the minimum $L^0$ norm of the control, is a continuous and strictly convex function of the initial state in the reachable set, under an assumption on the controlled plant model. This property is important, in particular, for discussing the sensitivity of the optimality against uncertainties in the initial state, and also for investigating the stability by using the value function as a Lyapunov function in model predictive control.

Key words: Optimal control, continuity, bang-bang control, discontinuous control, linear systems, minimum-time control.

1 Introduction

Optimal control is widely used in recent industrial products not just for achieving the best performance but for reducing the control effort. For example, the classical LQR (Linear Quadratic Regulator) control gives a way to consider the tradeoff between performance and control-effort reduction by using weighting functions on the states and the control inputs with the $L^2$ norm (i.e. the energy) \cite{1}.

Recently, a novel control method, called maximum hands-off control, that maximizes the time duration in which the control is exactly zero among the admissible controls \cite{10,12}. An example of hands-off control is a stop-start system in automobiles, in which an automobile automatically shuts down the engine (i.e. zero control) to avoid it idling for long periods of time, and also to reduce CO or CO2 emissions as well as fuel consumption. Therefore, the hands-off control is also called as green control \cite{11}. Also, the hands-off control is effective in hybrid/electric vehicles, railway vehicles, networked/embedded systems, to name a few \cite{12}.

Maximum hands-off control is related to sparsity, which is widely studied in compressed sensing \cite{3}. Sparsity is also applied to control problems such as networked control \cite{13,8}, security of control systems \cite{4}, state estimation \cite{15}, to name a few.

A mathematical difficulty in the maximum hands-off control is that the cost function, which is defined by the $L^0$ measure (the support length of a function), is highly nonlinear; it is discontinuous and non-convex. To solve this problem, a recent work \cite{10,12} has proposed to reduce the problem to an $L^1$ optimal control problem, and shown the equivalence between the maximum hands-off (or $L^0$ optimal) control and the $L^1$ optimal control under the assumption of normality.

Motivated by this work, we investigate the value function in the maximum hands-off control. The value function is defined as the optimal value of the cost function of the optimal control problem. It is important to show the continuity of the value function with respect to the initial state; if the value function is continuous, then the optimality property is less sensitive against uncertainties in the initial state. Also, the value function may be used as a Lyapunov function when the optimal control is adapted to model predictive control, and the continuity is necessary for the function to be a Lyapunov function \cite{9}. Although the $L^0$ measure in the maximum hands-off control is discontinuous and non-convex, we prove that the value function is a continuous and strictly convex function of the initial state in the reachable set, under an assumption on the controlled plant model.

The present paper expands on our recent conference contribution \cite{7} by rearranging the contents and incorporating analysis of convexity of the value function.

The remainder of this paper is organized as follows: In Section 2, we give mathematical preliminaries for our subsequent discussion. In Section 3, we review the problem of maximum hands-off control. Section 4 investigates the continuity of the value function in maximum hands-off control, and Section 5 discusses its convexity. Section 6 presents an example of maximum hands-off control to illustrate the properties of continuity and convexity. In Section 7, we offer concluding remarks.

## 2 Mathematical Preliminaries

This section reviews basic definitions, facts, and notation that will be used throughout the paper.

Let $n$ be a positive integer. For a vector $x \in \mathbb{R}^n$ and a scalar $\varepsilon > 0$, the $\varepsilon$-neighborhood of $x$ is defined by $B(x, \varepsilon) \triangleq \{ y \in \mathbb{R}^n : \| y - x \| < \varepsilon \}$, where $\| \cdot \|$ denotes the Euclidean norm in $\mathbb{R}^n$. Let $\mathcal{X}$ be a subset of $\mathbb{R}^n$. A point $x \in \mathcal{X}$ is called an interior point of $\mathcal{X}$ if there exists $\varepsilon > 0$ such that $B(x, \varepsilon) \subset \mathcal{X}$. The boundary of $\mathcal{X}$ is the set of all interior points of $\mathcal{X}$, and we denote the interior of $\mathcal{X}$ by $\text{int}\mathcal{X}$. A set $\mathcal{X}$ is said to be open if $\mathcal{X} = \text{int}\mathcal{X}$. For example, $\text{int}\mathcal{X}$ is open for every subset $\mathcal{X} \subset \mathbb{R}^n$. A point $x \in \mathbb{R}^n$ is called an adherent point of $\mathcal{X}$ if $B(x, \varepsilon) \cap \mathcal{X} \neq \emptyset$ for every $\varepsilon > 0$, and the closure of $\mathcal{X}$ is the set of all adherent points of $\mathcal{X}$. A set $\mathcal{X} \subset \mathbb{R}^n$ is said to be closed if $\mathcal{X} = \overline{\mathcal{X}}$, where $\overline{\mathcal{X}}$ is the closure of $\mathcal{X}$. The boundary of $\mathcal{X}$ is the set of all points in the closure of $\mathcal{X}$, not belonging to the interior of $\mathcal{X}$, and we denote the boundary of $\mathcal{X}$ by $\partial\mathcal{X}$, i.e., $\partial\mathcal{X} = \overline{\mathcal{X}} - \text{int}\mathcal{X}$, where $\mathcal{X}_1 - \mathcal{X}_2$ is the set of all points which belong to the set $\mathcal{X}_1$ but not to the set $\mathcal{X}_2$. In particular, if $\mathcal{X}$ is closed, then $\partial\mathcal{X} = \mathcal{X} - \text{int}\mathcal{X}$, since $\mathcal{X} = \overline{\mathcal{X}}$. A set $\mathcal{X} \subset \mathbb{R}^n$ is said to be convex if, for any $x, y \in \mathcal{X}$ and any $\lambda \in [0, 1]$, $(1 - \lambda)x + \lambda y$ belongs to $\mathcal{X}$.

A real-valued function $f$ defined on $\mathbb{R}^n$ is said to be upper semi-continuous on $\mathbb{R}^n$ if for every $\alpha \in \mathbb{R}$ the set $\{ x \in \mathbb{R}^n : f(x) < \alpha \}$ is open, and $f$ is said to be lower semi-continuous on $\mathbb{R}^n$ if for every $\alpha \in \mathbb{R}$ the set $\{ x \in \mathbb{R}^n : f(x) > \alpha \}$ is open. It is known that a function $f$ is continuous on $\mathbb{R}^n$ if and only if it is upper and lower semi-continuous on $\mathbb{R}^n$; see e.g., [14, pp. 37].

A real-valued function $f$ defined on a convex set $\mathcal{C} \subset \mathbb{R}^n$ is said to be convex if

$$f((1 - \lambda)x + \lambda y) \leq (1 - \lambda)f(x) + \lambda f(y),$$

for all $x, y \in \mathcal{C}$ and all $\lambda \in (0, 1)$, and $f$ is said to be strictly convex if the inequality (1) holds strictly whenever $x$ and $y$ are distinct points and $\lambda \in (0, 1)$.

Let $T > 0$. For a continuous-time signal $u(t)$ over a time interval $[0, T]$, we define its $L^1$ and $L^\infty$ norms respectively by

$$\| u \|_1 \triangleq \int_0^T |u(t)| dt, \quad \| u \|_\infty \triangleq \sup_{t \in [0, T]} |u(t)|.$$

We define the support set of $u$, denoted by $\text{supp}(u)$, by the closure of the set $\{ t \in [0, T] : u(t) \neq 0 \}$. The $L^0$ norm of a measurable function $u$ as the length of its support, that is, $\| u \|_0 \triangleq m(\text{supp}(u))$, where $m$ is the Lebesgue measure on $\mathbb{R}$.

## 3 Maximum Hands-off Control Problem

In this paper, we consider a linear time-invariant system represented by

$$\dot{x}(t) = Ax(t) + Bu(t), \quad t \geq 0, \quad (2)$$

where $x(t) \in \mathbb{R}^n$, $u(t) \in \mathbb{R}$, $A \in \mathbb{R}^{n \times n}$, and $B \in \mathbb{R}^{n \times 1}$. Throughout this paper, we assume the following:

**Assumption 1** The pair $(A, B)$ is controllable and the matrix $A$ is nonsingular.

Let $T > 0$ be the final time of control. For the system (2), we call a control $u = \{ u(t) : t \in [0, T] \} \in L^1$ admissible if it steers $x(t)$ from a given initial state $x(0) = \xi \in \mathbb{R}^n$ to the origin at time $T$ (i.e., $x(T) = 0$), and satisfies the magnitude constraint $\| u \|_\infty \leq 1$. We denote by $\mathcal{U}(\xi)$ the set of all admissible controls for an initial state $\xi \in \mathbb{R}^n$, that is,

$$\mathcal{U}(\xi) \triangleq \left\{ u \in L^1 : \int_0^T e^{-As} Bu(s) ds = -\xi, \| u \|_\infty \leq 1 \right\}. \quad (3)$$

The maximum hands-off control is the minimum $L^0$ norm (or the sparsest) control among the admissible control inputs. This control problem is formulated as follows.

**Problem 2 (Maximum hands-off control)** For a given initial state $\xi \in \mathbb{R}^n$, find an admissible control $u \in \mathcal{U}(\xi)$ that minimizes $J(u) = \| u \|_0$.

The value function for this optimal control problem is defined as

$$V(\xi) \triangleq \min_{u \in \mathcal{U}(\xi)} J(u) = \min_{u \in \mathcal{U}(\xi)} \| u \|_0. \quad (4)$$

Note that the cost function $J(u)$ can be rewritten as

$$J(u) = \int_0^T \phi_0(u) dt,$$

where $\phi_0(u)$ is a given non-negative cost function.
Fig. 1. The $L^0$ kernel $\phi_0(u)$ and its convex approximation $|u|$ for the $L^1$ norm.

where $\phi_0$ is the $L^0$ kernel function defined by

$$\phi_0(u) = \begin{cases} 1, & \text{if } u \neq 0, \\ 0, & \text{if } u = 0. \end{cases}$$

Fig. 1 shows the graph of $\phi_0(u)$. As shown in this figure, the kernel function $\phi_0(u)$ is discontinuous at $u = 0$ and non-convex. However, in the following sections, we will show that the value function $V(\xi)$ in (4) is continuous and strictly convex.

4 Continuity of Value Function

In this section, we investigate the continuity of the value function $V(\xi)$ in (4).

First, we define the reachable set for the control problem (Problem 2) by

$$\mathcal{R} \triangleq \left\{ \int_0^T e^{-As}Bu(s)ds : \|u\|_{\infty} \leq 1 \right\} \subset \mathbb{R}^n.$$  

The following is a fundamental lemma of the paper:

**Lemma 3** Suppose Assumption 1 is satisfied. Let us consider $L^1$ optimal control with

$$J_1(u) := \|u\|_1 = \int_0^T |u(t)|dt,$$

$$V_1(\xi) := \min_{u \in \mathcal{U}(\xi)} \|u\|_1.$$  

Then, for every $\xi \in \mathcal{R}$, we have $V(\xi) = V_1(\xi)$.

**PROOF.** By Assumption 1, the $L^1$-optimal control problem associate with (5) is normal [2, Theorem 6-13]. Then by [10, Theorem 5], $u^*$ is also the optimal control of Problem 2, and we have

$$V(\xi) = \min_{u \in \mathcal{U}(\xi)} \|u\|_0 = \|u^*\|_0 = \|u^*\|_1 = V_1(\xi),$$

where we used the “bang-off-bang” property of $u^*$ for the third equality. □

Note that the absolute value $|u|$ in (5) is a convex approximation of $\phi_0(u)$ as shown in Fig. 1. Associated with $V_1(\xi)$, we define the following subset of $\mathcal{R}$ with $\alpha \geq 0$:

$$\mathcal{R}_\alpha \triangleq \left\{ \int_0^T e^{-As}Bu(s)ds : \|u\|_{\infty} \leq 1, \|u\|_1 \leq \alpha \right\}.$$  

For the set $\mathcal{R}_\alpha$, we have another fundamental lemma.

**Lemma 4** Suppose Assumption 1 is satisfied. Then, for every $\alpha \in [0, T],$

$$\mathcal{R}_\alpha = \{ \xi \in \mathcal{R} : V(\xi) < \alpha \}.$$  

**PROOF.** See Appendix A. □

From these lemmas, we show the continuity of the value function $V(\xi)$.

**Theorem 5** If Assumption 1 is satisfied, then $V(\xi)$ is continuous on $\mathcal{R}$.

**PROOF.** Define

$$\nabla(\xi) \triangleq \begin{cases} V(\xi), & \text{if } \xi \in \mathcal{R}, \\ T, & \text{if } \xi \in \mathbb{R}^n - \mathcal{R}. \end{cases}$$

It is enough to show that $\nabla(\xi)$ is continuous on $\mathbb{R}^n$.

First, we show that the set

$$\left\{ \xi \in \mathbb{R}^n : \nabla(\xi) < \alpha \right\}$$  

is open for every $\alpha \in \mathbb{R}$. If $\alpha \leq 0$, then the set (10) is empty since for any $\xi \in \mathbb{R}^n$, $V(\xi) \geq 0$. If $\alpha > T$, then the set (10) is $\mathbb{R}^n$, since for any $\xi \in \mathbb{R}$, $V(\xi) \leq T$. If $0 < \alpha \leq T$, then the set (10) is a subset of $\mathcal{R}$, and coincides with $\text{int}\mathcal{R}_\alpha$ by Lemma 4. Therefore, the set (10) is open for every $\alpha \in \mathbb{R}$. It follows that $V(\xi)$ is upper semi-continuous on $\mathbb{R}^n$. 

Next, we show that the set
\[ \{ \xi \in \mathbb{R}^n : \nabla \xi > \alpha \} \]  
(11)
is open for every \( \alpha \in \mathbb{R} \). If \( \alpha < 0 \) or \( \alpha \geq T \), then the set (11) is \( \mathbb{R}^n \) or empty, respectively. If \( 0 \leq \alpha < T \), from Lemma 4, we have
\[ \{ \xi \in \mathbb{R}^n : \nabla \xi > \alpha \} = \mathbb{R}^n - \{ \xi \in \mathbb{R} : V(\xi) \leq \alpha \} = \mathbb{R}^n - \mathcal{R}_\alpha. \]
Since \( \mathcal{R}_\alpha \) is closed (see Lemma 8 in Appendix A), the set (11) is open for every \( \alpha \in \mathbb{R} \). It follows that \( \nabla \xi \) is lower semi-continuous on \( \mathbb{R}^n \).

Since \( \nabla \xi \) is upper and lower semi-continuous on \( \mathbb{R}^n \), it is continuous on \( \mathbb{R}^n \), and the conclusion follows. \( \square \)

Theorem 5 leads to an important result of \( L^1 \) optimal control as follows.

**Corollary 6.** If Assumption 1 is satisfied, then \( V_1(\xi) \) is continuous on \( \mathcal{R} \).

**PROOF.** This is a direct consequence of Lemma 3 and Theorem 5. \( \square \)

## 5 Convexity of Value Function

Here we show the convexity of the value function \( V(\xi) \). Although the kernel function \( \phi_0(u) \) in the cost function is not convex as shown in Fig. 1, the value function \( V(\xi) \) is a convex function on \( \mathcal{R} \).

**Theorem 7.** If Assumption 1 is satisfied, then \( V(\xi) \) is strictly convex on \( \mathcal{R} \).

**PROOF.** From Lemma 3, it is enough to prove that the \( L^1 \) value function \( V_1(\xi) \) is strictly convex on \( \mathcal{R} \).

First, we prove that \( V_1(\xi) \) is convex on \( \mathcal{R} \). Take any \( \xi, \eta \in \mathcal{R} \), and \( \lambda \in (0, 1) \). Then there exist \( L^1 \)-optimal controls \( u_\xi \) and \( u_\eta \) for initial states \( \xi \) and \( \eta \), respectively (see Lemma 10 in Appendix A). Obviously, the following control
\[ u \triangleq (1 - \lambda)u_\xi + \lambda u_\eta \]  
(12)
steers the state from the initial state \( (1 - \lambda)\xi + \lambda \eta \) to the origin at time \( T \), and it satisfies \( \|u\|_\infty \leq 1 \). That is, we have \( u \in \mathcal{U}(1 - \lambda)\xi + \lambda \eta \). Therefore
\[ V_1((1 - \lambda)\xi + \lambda \eta) \leq \|u\|_1 \leq (1 - \lambda)\|u_\xi\|_1 + \lambda\|u_\eta\|_1 \]  
(13)
\[ = (1 - \lambda)V_1(\xi) + \lambda V_1(\eta), \]
and hence \( V_1(\xi) \) is convex on \( \mathcal{R} \).

Next, we will show the strict convexity of \( V(\xi) \). To prove this, we will show that a contradiction is implied by assuming that there exist \( \xi, \eta \in \mathcal{R} \) with \( \xi \neq \eta \) and \( \lambda \in (0, 1) \) such that
\[ V_1((1 - \lambda)\xi + \lambda \eta) = (1 - \lambda)V_1(\xi) + \lambda V_1(\eta). \]  
(14)

Let \( u_\xi \) and \( u_\eta \) be \( L^1 \)-optimal controls for initial states \( \xi \) and \( \eta \), respectively. Let \( u \triangleq (1 - \lambda)u_\xi + \lambda u_\eta \) as in (12). From (13) and (14), it follows that
\[ V_1((1 - \lambda)\xi + \lambda \eta) = \|u\|_1 = (1 - \lambda)\|u_\xi\|_1 + \lambda\|u_\eta\|_1, \]
so the control \( u = (1 - \lambda)u_\xi + \lambda u_\eta \) is an \( L^1 \)-optimal control for the initial state \( (1 - \lambda)\xi + \lambda \eta \).

Now, by Assumption 1, \( u_\xi(t) \) and \( u_\eta(t) \) take the values 1, 0, and \(-1\) at almost all \( t \in [0, T] \). So, the pair \((u_\xi(t), u_\eta(t))\) takes the following values on \([0, T] \) except for sets of measure zero:
\[ (1, 1), (1, 0), (1, -1), (0, 1), (0, 0), \]
\[ (0, -1), (-1, 1), (-1, 0), (-1, -1). \]  
(15)

For the pairs in (15) of \((u_\xi(t), u_\eta(t))\), the control \( u = (1 - \lambda)u_\xi + \lambda u_\eta \) respectively takes the following values:
\[ 1, 1 - \lambda, 1 - 2\lambda, \lambda, 0, -\lambda, -1 + 2\lambda, -1 - \lambda, -1. \]

On the other hand, the control \( u \) is also \( L^1 \) optimal and takes the values 1, 0, and \(-1\) at almost all \( t \in [0, T] \).

Since \( \lambda \in (0, 1) \), we have
\[ m(\mathcal{I}_{1,0} \cup \mathcal{I}_{0,1} \cup \mathcal{I}_{-1,0} \cup \mathcal{I}_{-1,1}) = 0, \]  
(16)

where \( \mathcal{I}_{i,j} \triangleq \{ t \in [0, T] : (u_\xi(t), u_\eta(t)) = (i, j) \} \), for \( i, j \in \{-1, 0, 1, \} \). If \( \lambda \neq 1/2 \), then we also have
\[ m(\mathcal{I}_{1,-1} \cup \mathcal{I}_{-1,1}) = 0, \]
and it follows that
\[ m(\mathcal{I}_{1,1} \cup \mathcal{I}_{0,0} \cup \mathcal{I}_{-1,-1}) = T, \]
that is, \( u_\xi(t) = u_\eta(t) \) for almost all \( t \in [0, T] \). This implies \( \xi = \eta \), but this contradicts the assumption, so we have \( \lambda = 1/2 \). Then the pair \((u_\xi(t), u_\eta(t))\) on \([0, T] \) except for sets of measure zero takes values \((1, 1), (1, -1), (0, 0), (-1, 1), (-1, -1) \). Since \( \xi \neq \eta \), we have
\[ T_1 \triangleq m(\mathcal{I}_{1,-1} \cup \mathcal{I}_{-1,1}) > 0. \]  
(17)
Let $T_2 \triangleq m(I_{1,1})$ and $T_3 \triangleq m(I_{-1,-1})$. From (16) and the fact that $u_\xi + u_\eta = 0$ on $I_{1,-1} \cup I_{-1,1} \cup I_{0,0}$, we have

$$V_1\left(\frac{1}{2}\xi + \frac{1}{2}\eta\right) = \left\|\frac{1}{2}u_\xi + \frac{1}{2}u_\eta\right\|_1 = \frac{1}{2}\int_{I_{1,1} \cup I_{-1,-1}}|u_\xi(t) + u_\eta(t)|dt = T_2 + T_3,$$

(18)

On the other hand,

$$\frac{1}{2}V_1(\xi) + \frac{1}{2}V_1(\eta) = \frac{1}{2}\|u_\xi\|_1 + \frac{1}{2}\|u_\eta\|_1 = T_1 + T_2 + T_3,$$

(19)

Equations (14), (18) and (19) imply that $T_1 = 0$, which contradicts (17). \(\square\)

6 Example

In this section, we consider a simple example with a 1-dimensional linear control system

$$\dot{x}(t) = ax(t) + bu(t),$$

where $a < 0$ and $b \neq 0$. This system obviously satisfies Assumption 1, and let us verify the continuity and convexity of the value function $V(\xi)$ on the reachable set $\mathcal{R}$.

The reachable set $\mathcal{R}$ and the maximum hands-off control $u_\xi$ for an initial state $\xi \in \mathcal{R}$ are computed via the bang-bang principle [6, Theorem 12.1] and the minimum principle for $L^1$-optimal control [2, Section 6.14] as

$$\mathcal{R} = [-x_1, x_1], \quad x_1 = -b|a|^{-1}(e^{-aT} - 1),$$

and

$$u_\xi(t) = \begin{cases} 0, & t \in [0, \tau_\xi), \\ -\text{sgn}(b)\text{sgn}(\xi), & t \in [\tau_\xi, T], \end{cases}$$

where $\text{sgn}(x) = x/|x|$ for $x \neq 0$ and $\text{sgn}(0) = 0$, and

$$\tau_\xi \triangleq -a^{-1}\log(e^{-aT} + a|b^{-1}\xi|).$$

Note that if $\xi = 0$, then $u_0(t) = 0$ for all $t \in [0, T]$. Then we have

$$V(\xi) = T - \tau_\xi = T + a^{-1}\log(e^{-aT} + a|b^{-1}\xi|).$$

For example, let $a = -1$, $b = 1$, and $T = 5$. Fig. 2 shows the value function $V(\xi)$ on $\mathcal{R}$, where $\mathcal{R} = [-e^5 + 1, e^5 - 1]$. Certainly, we can see that $V(\xi)$ is continuous and strictly convex on $\mathcal{R}$.

Fig. 2. Value function $V(\xi)$ for $\xi \in \mathcal{R} = [-e^5 + 1, e^5 - 1]$

7 Conclusion

In this brief paper, we have proved the continuity and the strict convexity of the value function of the maximum hands-off control problem under an assumption of the controlled system. Also, as a corollary we have shown that those properties are also satisfied for $L^1$ optimal control under the same assumption. These properties of the value function plays an important role to investigate the stability when we extend the control to the model predictive control.

A Proof of Lemma 4

A.1 Lemmas

To prove Lemma 4, we need some lemmas.

Lemma 8 The set $R_\alpha$ in (6) satisfies the following:

1. For every $\alpha \in R$, $R_\alpha$ is compact.
2. For every $\alpha \in R$, $R_\alpha \subset R$, with equality for $\alpha \geq T$.
3. $R_0 = \{0\}$.
4. $R_\alpha \subset R_\beta$ for $0 \leq \alpha \leq \beta$.

PROOF. See [5, Lemma 2.1]. □

Lemma 9 For every $\alpha \in [0, T]$, we have

$R_\alpha = \{\xi \in R : \exists u \in U(\xi) \text{ s.t. } \|u\|_1 \leq \alpha\}$.

PROOF. First, fix $\alpha \in [0, T]$ and take any $\xi \in R_\alpha$. Then, by the definition of $R_\alpha$, there exists $u \in U(\xi)$ such that $\|u\|_1 \leq \alpha$ and

$\xi = \int_0^T e^{-As}Bu(s)ds$.

From (3), it follows that the control $v := -u$ is an admissible control, that is, $v \in U(\xi)$, and also satisfies $\|v\|_1 = \|u\|_1 \leq \alpha$. By definition, $R_\alpha \subset R$ and hence $\xi \in R$. Therefore, we have $\xi \in \{\xi \in R : \exists u \in U(\xi) \text{ s.t. } \|u\|_1 \leq \alpha\}$.

Conversely, fix $\alpha \in [0, T]$ and take any $\xi \in \{\xi \in R : \exists u \in U(\xi) \text{ s.t. } \|u\|_1 \leq \alpha\}$. That is, $\xi \in R$ is an initial state for the system (2), and there exists an admissible control $u \in U(\xi)$ such that $\|u\|_1 \leq \alpha$. Then from (3), we have

$\xi = \int_0^T e^{-As}B(-u(s))ds$.

The control $v = -u$ satisfies $\|v\|_1 = \|u\|_1 \leq \alpha$, $\|v\|_\infty = \|u\|_\infty \leq 1$, and hence we have $\xi \in R_\alpha$. □

Lemma 10 For each initial value $\xi \in R$, there exists an admissible control $u \in U(\xi)$ with minimal L1-cost $\|u\|_1$.

Furthermore, then, $\xi \in \partial R_\alpha$ with $\alpha = \|u\|_1$.

PROOF. See [5, Lemma 3.1]. □

A.2 Proof of (7)

First, fix $\alpha \in [0, T]$ and take any $\xi \in R_\alpha$. Then, from Lemma 8, we have $\xi \in R$, and from Lemma 10, there exists an $L^1$-optimal control $u^* \in U(\xi)$. Also, we have $V_1(\xi) = \|u^*\|_1 \leq \alpha$ by Lemma 9. Then, from Lemma 3, we have $V(\xi) \leq \alpha$. That is, we have $\xi \in \{\xi \in R : V(\xi) \leq \alpha\}$.

Conversely, fix $\alpha \in [0, T]$ and take any $\xi \in \{\xi \in R : V(\xi) \leq \alpha\}$. From Lemma 3, we have $V_1(\xi) \leq \alpha$. Let $\beta \triangleq V_1(\xi)$. From Lemma 10, we have $\xi \in \partial R_\beta$, and it follows from Lemma 8 that $\xi \in \partial R_\beta \subset R_\beta \subset R_\alpha$.

A.3 Proof of (8) and (9)

We prove the equation (8); then the equation (9) follows immediately from (7) and (8), since $R_\alpha$ is closed for every $\alpha \geq 0$ from Lemma 8. If $\alpha = 0$, then $\partial R_0 = \{0\}$, since $R_0 = \{0\}$. It follows from (7) that

$\{\xi \in R : V(\xi) = 0\} = R_0 = \{0\} = \partial R_0$.

Fix $\alpha \in (0, T)$. We can take $\xi \in \partial R_\alpha$, since $\partial R_\alpha$ is not empty. Since $\xi \in R_\alpha$, we have $V(\xi) \leq \alpha$. If $V(\xi) < \alpha$, then $\xi \in \partial R_{V(\xi)} \subset R_{V(\xi)} \subset \text{int } R_\alpha$ (see [5, Lemma 4.2]), and hence a contradiction occurs. Therefore we have $V(\xi) = \alpha$, and hence $\partial R_\alpha \subset \{\xi \in R : V(\xi) = \alpha\}$ and $\{\xi \in R : V(\xi) = \alpha\}$ is not empty for every $\alpha \in (0, T]$. Then it follows from Lemma 10 that

$\{\xi \in R : V(\xi) = \alpha\} \subset \partial R_\alpha$

for every $\alpha \in (0, T]$, and the conclusion follows.

\footnote{\textit{Rn} and the empty set are the only subsets whose boundaries are empty, since \textit{Rn} is connected [16, Chapter 3].}
