Abstract: The substantial improvements in transmission voltage, which have been adopted to meet fast-growing energy demands, require more reliable power equipment and higher-quality insulating materials. The polytetrafluoroethylene (PTFE) nozzle, as the key part of a high-voltage circuit breaker, is often subjected to arc ablation and breakdown phenomena. Thus, it is very urgent to develop nozzles with better performance. In this study, PTFE/boron nitride (BN) composites were prepared. The relationships among the BN filler loading, thermal transition properties, spectral reflectance properties, arc ablation resistance, and AC dielectric breakdown performances, as well as their corresponding mechanisms, were studied. Experimental results show that the thermal conductivity and thermal diffusivity of PTFE/BN composites increased monotonously with BN loading, and that both parameters were improved by 41% and 44%, respectively, for 11 wt % composites compared with pure PTFE. Moreover, PTFE/BN composites had higher light reflectance in the wavelength range from 320 to 2500 nm. The PTFE/BN composites presented better arc ablation resistance performance with increased BN loading, which was improved by 88.5%. It is thought that the increased thermal conductivity, thermal diffusivity, the strong light reflectance, and surface sediment after arc ablation contribute to the improvement in arc ablation resistance performance. The AC breakdown strength of PTFE/BN composites was enhanced by 30.93%, attributed to the good heat dissipation properties introduced by the BN fillers. Thus, filling BN into the PTFE matrix would be helpful to solve the equipment issue that comes from the improvement in transmission voltage.

Keywords: PTFE; BN; arc ablation; breakdown; thermal conductivity

1. Introduction

Ultra-high voltage (UHV) transmission technologies are widely used in power transmission all over the world due to their high transmission voltages and large transmission capacities [1,2]. In 2019, the world’s first ±1100 kV DC transmission line from Zhundong to Wannan in China was put into operation, belonging to the highest voltage class and having the largest transmission capacity in the world [3]. However, the increased transmission voltage placed higher requirements on dielectric materials [4].

A nozzle is used to confine the electrical arc and guide the gas flow within circuit breakers, which are usually used for controlling circuit breaking in power systems [5]. Polytetrafluoroethylene (PTFE) is the raw insulating material used for processing nozzles due to its excellent insulation properties and machinability. However, the arc created during the switching-off process ablates and causes breakdown of the PTFE nozzle, seriously affecting the breaking performance of circuit breakers [6–10]. Therefore, it is essential to investigate the arc ablation and the breakdown properties of these nozzles and to develop better nozzle materials to solve or mitigate the above problems. In recent years, many studies on the
arc model and establishing the dynamic properties of gases during the breaking process of the circuit breaker have been carried out [10–15], but few works have focused on the investigation of the ablation and breakdown properties of nozzles. Our previous work superficially studied the arc ablation resistance and breakdown properties of nozzle materials by filling BN of different sizes into PTFE [16,17]. It was found that arc ablation resistance is positively related with the thermal conductivity of the composites. Thus, enhancement in the thermal transport performance of nozzle materials may improve arc ablation resistance performance. The thermal transport performance of polymers can be enhanced by the following two ways: optimizing the structures of the polymers themselves or by filling their matrices with high-thermal-conductivity fillers (the filled polymers) [18–25]. Compared with the former methods, the latter methods have attracted much attention because the polymeric composites are easily achieved. For the polymeric composites, many fillers with high thermal conductivity, such as metal powder [18], metal oxide [19], metal or non-metal nitrides [20–23], and graphene [24,25], can be used to enhance thermal transport performance. Therefore, it is essential to select appropriate fillers according to the actual demand. It was reported that the thermal conductivity of hexagonal boron nitride (h-BN) is up to 280 W/(m·K) [23] and is a good choice to improve the thermal transport performance of polymeric composites.

In this study, PTFE filled with various h-BN loadings was prepared to investigate the arc ablation and AC breakdown properties; the surface morphology before and after arc ablation, thermal transport, and spectral reflectance properties of PTFE/BN specimens were tested to investigate the corresponding mechanisms.

2. Experimental Section
2.1. Preparation of PTFE/BN Specimens

PTFE with a size of about 25 μm, supplied by Japan Daikin Corporation, and h-BN sheets with an average size of 5 μm, supplied by Beijing Deke Daojin Science and Technology Co., Ltd., were used for the preparation of PTFE/BN composites. A certain weight ratio of PTFE and h-BN powder were placed into a high-speed mixer and then mixed at a speed of 1000 rpm for 1 h. Then, the mixture was preprocessed into a cylindrical shape with a diameter of 80 mm and a height of 100 mm through the isostatic pressing method, with a pressure of 15 MPa for 30 min. The pressure was then released, and the prefabricated cylinder was placed into a sintering furnace for sintering. Several sintering procedures as shown in Figure 1 were carried out, separately. The prefabricated product was, firstly, heated from room temperature to 320 °C with a heating rate of 5 °C/min, and then this temperature (320 °C) was maintained for 30 min. After that, the temperature was increased from 320 to 340 °C with a heating rate of 2 °C/min, and then maintained at 340 °C for 30 min. Then, the temperature was increased to 370 °C in 30 min and maintained for 3 h before being naturally cooled to room temperature. Finally, six types of specimens with BN filler loading of 0, 3, 5, 7, 9, and 11 wt % were prepared, and the corresponding specimens were named PTFE, PTFE-BN-3, PTFE-BN-5, PTFE-BN-7, PTFE-BN-9, and PTFE-BN-11, respectively.
2.2. Characterization of PTFE/BN Composites

A scanning electron microscope (SEM) of JSM-6930 was used to observe the dispersion of BN sheets in PTFE matrix, as well as the surface morphology of specimens after ablation. To observe the dispersion of BN sheets in PTFE, the fracture surface was obtained by breaking off the specimen in liquid nitrogen, which was then surface-sprayed with a layer of gold. For surface morphology observation of the arc ablation regions, the selected region was directly coated with a gold layer. After that, the SEM specimens were prepared.

LFA447 Nanoflash equipment was used to measure the thermal transport properties of specimens, including their thermal conductivity and thermal diffusivity. Firstly, the specimens were processed into a square with a thickness of 2 mm and a side length of 10 mm and dried in an oven at 60 °C for 5 h. Then, the dried specimens were surface-sprayed with graphite powder. After that, the prepared specimens could be used for testing. In this study, the testing temperature was started at 50 °C and ended at 275 °C, with a temperature interval of 25 °C. In this study, each specimen was tested 3 times, and the average value was used to characterize the thermal transport performances.

The spectral reflectance of PTFE/BN composites was tested by UV–Vis spectroscopy. The related research indicated that the wavelength of the arc ranges from 30 nm to 1.8 μm [26]. However, the equipment cannot test the spectral properties when the wavelength is below 200 nm. Thus, during testing, the wavelength ranged from 200 to 2500 nm, including the ultraviolet region, the visible light region, and the infrared region.

Arc ablation resistance performance was measured based on IEC 61621. The testing equipment and the testing program were the same as in [16]. Specimens were placed between two-finger tungsten electrodes with a gap of 6.35 mm, and the created arc ablated the specimens. The arc ablation resistance performance of the specimens was characterized by the amount of ablation, which is calculated by the weight difference before and after the arc ablation test. In this study, each specimen was tested 5 times, and the average arc ablation amount was defined as the arc ablation resistance performance.

The AC dielectric breakdown strength was measured with HJC-100 kV breakdown equipment according to ASTM D 149 standard, the same as in Ref. [17]. The tested specimens, with 0.5 mm thickness, were sandwiched between two spherical electrodes with a diameter of 25 mm and were put into the insulating oil at room temperature. During the tests, the voltage applied to the specimens was increased at a rate of 5 kV/s until breakdown occurred, and the breakdown voltage was recorded. Finally, the breakdown strength was obtained by the ratio of breakdown voltage to the specimen’s thickness. In this study, the breakdown of each sample was tested 10 times, and the average breakdown strength was used for characterizing the dielectric strength of the specimens.

3. Experimental Results

3.1. SEM Characterization

Figure 2 shows the SEM images of PTFE/BN specimens with various BN loadings. From Figure 2b–f, it can be seen that the shape of BN is a sheet, with a size of about 5 µm. In addition, the SEM images show that the BN sheets are distributed very uniformly in the PTFE matrix, and almost no agglomeration phenomenon were observed in the PTFE/BN composites. It seems that the distances between the BN sheets decrease gradually with increased BN filler loading. For instance, BN sheets are isolated within the PTFE with low BN loading, as shown in Figure 2b. Whereas in Figure 2d–f, the BN sheets are close to one other with the increase in filler loadings.

Figure 2. SEM images of (a) PTFE, (b) PTFE-BN-3, (c) PTFE-BN-5, (d) PTFE-BN-7, (e) PTFE-BN-9, and (f) PTFE-BN-11.
3.2. Thermal Transport Properties

The thermal transport performances of the PTFE/BN composites were characterized by thermal conductivity, and the results can be seen in Figure 3. It is obvious that the thermal conductivity increases with increased BN loading at every temperature point, and that all of the PTFE/BN composites present higher thermal transport performance than pure PTFE. The PTFE-BN-11 specimen shows the best thermal conductivity of 0.481 W/(m·K), which improved by 41% compared with that of unfilled PTFE (0.341 W/(m·K)) at 50 °C. Thermal conductivity is defined as the amount of heat transferred per unit of time by a unit of heat transfer surface. Thus, the improvement in thermal conductivity means more heat energy can be transferred in the same condition.

Figure 3. Thermal conductivity of specimens from 50 to 275 °C.

Figure 4 shows the thermal diffusivity of PTFE and PTFE/BN composites. It indicates that the thermal diffusivity of specimens increased with increased BN loading. For PTFE alone, the value of thermal diffusivity is 0.128 mm²/s, while it reaches up to 0.185 mm²/s when the BN concentration is 11 wt%; it improved by 44%. Thermal diffusivity reflects the ability of an object to reach a uniform temperature. This means the higher thermal diffusivity, the more quickly heat transfers.

Figure 4. Thermal diffusivity of PTFE and PTFE/BN specimens.
In recent years, h-BN was found to be structurally similar to graphite and shows equally excellent thermal transport performance [22]. In this study, h-BN with high thermal conductivity, as the inorganic filler, was added into PTFE to enhance the thermal transport performance. According to heat conduction theory, the thermal transport performance of polymer composites is mainly determined or influenced by the interaction role of the polymer matrix and the fillers [27]. In this study, the filled BN sheets were seen as the isolated heat conduction centers. These centers uniformly distributed in the PTFE matrix and formed different thermal paths. These paths were reticulated, chain-like, and interconnected with each other, forming a strong heat conduction network inside the material, and improving thermal conductivity [28, 29]. Thus, the more the heat conduction centers, the more easily interconnected the heat conduction network constructed, and the higher the thermal conductivity. In this paper, the experimental results agree with the above analysis. That is, the thermal conductivity of PTFE/BN composites increased gradually with increased BN loading.

3.3. Spectral Reflectance Properties

The results of the spectral reflectance properties of PTFE and PTFE/BN specimens are shown in Figure 5. Firstly, it was found that the intensity differences in light reflection between the PTFE and the PTFE/BN composites are obviously different. For neat PTFE, the light reflectance is obviously lower than that of PTFE/BN composites when the wavelength is longer than 320 nm (including ultraviolet light, visible light, and infrared light), and it decreases quickly with increased wavelength. However, the light reflectance of PTFE/BN composites is quickly enhanced with increased wavelength when it is longer than 320 nm, which is totally inversed compared with PTFE alone. Secondly, it was still observed that the light reflectance becomes gradually stronger with the increased BN loading in the area from 320 to 2500 nm, although the differences are not very clear. When the wavelength is less than 320 nm, it seems that the PTFE has the highest light reflectance, and that this decreases with BN loading. It is obvious that the high light reflectance of PTFE/BN composites was caused by the filled BN sheets. This may be due to the uniform dispersion of BN sheets in the PTFE matrix, and thus a small amount of BN filler loading could have greatly improved the light reflectance. However, the deeper causes require further study.

![Figure 5. Spectral reflectance of PTFE and PTFE/BN specimens.](image-url)
3.4. Surface Sediment Properties

Figure 6 shows the surface morphologies of specimens before and after arc ablation. It was found that two different regions exist on the specimen surface (green line is the actual boundary between the arc ablation region and the non-ablation region). The left of the green line is the non-ablation region, while the right of the green line is the arc ablation region. In the arc ablation region, it was observed that some sediment deposited on the surface of the specimens (Figure 6b–d). In addition, the amount of the sediment increased with increased BN loading. In the arc ablation process, the PTFE molecules decompose, firstly under the high temperature and the strong ultraviolet light of the arc; subsequently, the filled BN particles are left on the composites’ surfaces. Therefore, it is understandable that the sediment was only observed on PTFE/BN composites, as well as the increased amount of the sediment with increased BN loading.

3.5. Arc Ablation Properties

The arc ablation resistance performance results are shown in Figure 7. These indicate that the amount of arc ablation decreases with increased BN loading, which means the arc ablation resistance performance improves considerably. For example, the arc ablation amounts were 22.7, 21.1, 16.2, 14.9, 2.77, and 2.65 mg, respectively, for neat PTFE and all of the PTFE/BN specimens, from low BN loading to high BN loading. The weight loss decreased by 88.5% for PTFE-BN-11 sample compared with that of unfilled PTFE. This obvious decline in ablation mass would be very helpful for nozzles to prolong their service life and improve the operation reliability of circuit breakers.

Figure 7. Arc ablation resistance of PTFE/BN composites with various BN loadings.

3.6. AC Breakdown Performances

Figure 8 shows the AC breakdown characteristics of PTFE/BN composites. The error bar and the solid column are standard deviation and the average breakdown strength of 10 samples, respectively. It shows that the AC breakdown strength ($E_{AC}$) of specimens increased monotonously with increasing BN filler loading when the filler loading was below 9 wt % ($E_{AC}$ is 40.3 kV/mm for PTFE-BN-9 specimen). With further increases in BN filler loading, the $E_{AC}$ remained a stable value ($E_{AC}$ is 40.8 kV/mm for PTFE-BN-11 specimen). Compared with pure PTFE ($E_{AC}$ is 31.16 kV/mm), the highest $E_{AC}$ of PTFE-BN-11 was enhanced by 30.93%.

Figure 8. Influence of BN filler-content on $E_{AC}$ of PTFE/BN composites.

4. Discussion

To investigate, in detail, the factors enhancing arc ablation resistance and AC dielectric breakdown performance, the influences of thermal conductivity on the arc ablation amount and $E_{AC}$ of specimens are shown in Figure 9. It seems that the amount of arc ablation decreases and breakdown strength increases with increases in thermal conductivity, which means that the higher the thermal conductivities, the more excellent the arc ablation resistances and breakdown performances. The above results indicate that the thermal transport property has obvious influences on the arc ablation and dielectric characteristics of nozzle materials. The detailed explanations are given as follows.
in Section 3.4 that the surface sediments are the residual BN sheets after arc ablation. These BN sheets cover the surface of the ablation region and form a protective layer, which could prevent the subsequent ablation of inner PTFE material.

When a high temperature of tens of thousands of degrees is continuously subjected to polymers, the materials decompose. Therefore, avoiding heat accumulation and making the heat transfer away as much as possible are very important. In this study, the improved thermal conductivity and thermal diffusivity of the PTFE/BN composites were critical to reduce the arc heat accumulation. The increased thermal conductivity means more heat energy could be transferred, while the increased thermal diffusivity means heat could be more quickly diffused into the surrounding medium. Thus, both the thermal conductivity and thermal diffusivity of the PTFE/BN composites increased, which resulted in a faster and greater amount of heat transport to the surrounding material, which then decreased excessive accumulation of heat in a local area during arc ablation. Finally, the performance of arc ablation resistance was improved.

In addition to the above causes, the surface sediment may have been another factor that improved the arc ablation performance of the PTFE/BN composites. It is mentioned in Section 3.4 that the surface sediments are the residual BN sheets after arc ablation. These BN sheets cover the surface of the ablation region and form a protective layer, which could prevent the subsequent ablation of inner PTFE material.

Thermal dielectric breakdown theory [31,32] can be used to explain the improvement in $E_{AC}$. According to the thermal breakdown model, when the heat accumulation exceeds the heat dissipation by a certain value during voltage application, breakdown occurs. Thus, the reduction in heat accumulation is conducive to dielectric strength. Especially for the AC condition, this heat is created through dielectric loss during the voltage polarity,
periodically. Our experiment results are consistent with the above analysis. It is obvious that AC breakdown strength increases with increasing thermal conductivity of specimens. Refs. [20,33,34] reported a similar result to our study, which is that the addition of BN (10 wt %) results in the enhancement in both thermal conductivity and breakdown strength.

5. Conclusions

In this study, PTFE/BN composites were prepared to investigate the effect of BN loading on arc ablation and breakdown performances, as well as the corresponding mechanisms. Finally, some conclusions were formed as follows:

The thermal conductivity and thermal diffusivity of PTFE/BN composites increased by 41% and 44%, respectively, with increased BN loading compared with those of pure PTFE. The improvement in thermal conductivity was mainly attributed to the enhancement of thermal diffusivity. The light reflectance also obviously increased for PTFE/BN composites when the wavelength was longer than 320 nm.

The arc ablation resistance performance of PTFE/BN composites was greatly improved with increased BN loading. It was improved by 88.5% for PTFE-BN-11 specimens when compared with pure PTFE. These excellent performances can be attributed to the increases in thermal conductivity, thermal diffusivity, and light reflectance, and the resistance role of surface sediment created during the arc ablation process.
