Submitted 2 December 2012

During previous numerical experiments on isotropic turbulence of surface gravity waves we observed formation of the long wave background (condensate). It was shown (Korotkevich, Phys. Rev. Lett. 101(7), 074504 (2008)), that presence of the condensate changes a spectrum of direct cascade, corresponding to the flux of energy to the small scales from pumping region (large scales). Recent experiments show that the inverse cascade spectrum is also affected by the condensate. In this case mechanism proposed as a cause for the change of direct cascade spectrum cannot work. But inverse cascade is directly influenced by the linear dispersion relation for waves, as a result direct measurement of the dispersion relation in the presence of condensate is necessary. We performed the measurement of this dispersion relation from the direct numerical experiment. The results demonstrate that in the region of inverse cascade influence of the condensate cannot be neglected.

Theory of wave or weak turbulence [1] applied to gravity waves on the surface of the fluid is the base for all current wave forecasting models, which are crucial for ocean cargo communications and oil and gas sea platforms operations. This is why it’s verification is important and urgent problem. Numerous attempts to get a spectrum of the direct cascade of energy from ocean and sea observations give results which confirm the wave turbulence theory [2, 3]. At the same time all these experiments were working with wind generated waves, which means broad spectrum pumping. As a result it is hard to understand where we have so called “inertial interval” (region of scale where we have only nonlinear interaction of waves, while pumping and damping influences are negligible). Narrow frequency pumping can be realized in experimental wave tanks and flumes. But this state of the art experiments were producing very strange and contradictory results [4, 5], like dependence of the spectral slope on the amplitude of pumping. The direct numerical simulation of the primordial dynamical equations looks like a natural remedy for this problem. It provides us with all possible information about the system, but for the cost of enormous computational complexity.

One of the first attempts was pioneering work [6], which soon was followed by [7–9]. During the last decade, the author together with colleagues were able to find answers at least to some of the open questions using direct numerical simulation of gravity waves. It was shown, that on a discrete grid of wavenumbers (common situation for both pseudo spectral numerical codes in a periodic domain and experimental wave tanks which are usually rectangular basins of finite size) the mesoscopic turbulence can take place [10, 11]. In the recent works [12, 13] the author demonstrated that formation of the inverse cascade, corresponding to the flux of wave action (analog of number of waves), inevitably leads to the formation of the strong long wave background, which we call condensate (due to similarity with Bose-Einstein condensation in condensed matter physics). It was shown that presence of the condensate changes the slope of the direct cascade spectrum. In these recent experiments, in spite of the short inertial interval for the inverse cascade, the slope significantly different from the predicted by the wave turbulence theory was observed. Recent reports [14] with long enough inertial interval show that the slope is indeed differs from the theoretically predicted one.

In the present Letter we report results of direct measurement of the dispersion relation of the surface gravity waves in the presence of condensate. As it will be demonstrated later, the slope of the spectrum of the inverse cascade directly depends on the power of the dispersion relation. Although we were not able to determine the change of this power, we demonstrate that in the region of the inverse cascade the dispersion relation is strongly affected by the nonlinear interaction with the condensate. This distortion cannot be neglected and might be considered as a possible cause of the change of the slope of the inverse cascade spectrum.
In reality we should use pair correlator for variables after canonical transformation which eliminates nonresonant terms in the Hamiltonian \[11\], but in the case of gravity waves of average steepness \(\sqrt{\langle \nabla \eta^2 \rangle} \simeq 0.1\) their relative difference is of the order of few percents. Thus we neglect this difference and will be working with correlation function given above.

\[\gamma_k = \begin{cases} \frac{\sin k_0 d}{k_0 d}, & 0, k \leq k_d, \\ -\frac{\sin (k - k_d) d}{k - k_d}, & k > k_d, \end{cases} \]  

(3)

where \(k_d = 256\) and \(\gamma_{0,256} = 2.7 \times 10^4\) for the grid \(1024 \times 1024\) and \(k_d = 64\) and \(\gamma_{0,256} = 2.4 \times 10^2\) for the smaller grid \(256 \times 256\). Pumping was an isotropic driving force narrow in wavenumbers space with random phase:

\[P_k = f_k e^{i R_k(t)}, f_k = \begin{cases} 4 F_0 (\frac{k-k_{p1}}{k_{p2}-k_{p1}})^2, & 0 < k < k_{p1}, or k > k_{p2}; \end{cases} \]  

(4)

here \(k_{p1} = 28\), \(k_{p2} = 32\) and \(F_0 = 1.5 \times 10^{-5}\). \(R_k(t)\) was uniformly distributed random number in the interval \((0, 2\pi)\) for each \(k\) and \(t\). Initial condition was low amplitude noise in all harmonics. Time steps were \(\Delta t_{1024} = 6.7 \times 10^{-4}\) and \(\Delta t_{256} = 5.0 \times 10^{-3}\). We used Fourier series in the following form:

\[\eta_{k} = F_\eta F_k, \eta_{\eta} = F_\eta^2 = \frac{1}{(2\pi)^2} \int_0^{2\pi} \int_0^{2\pi} \eta_k e^{i k r} d^2r, \]

\[\eta_r = F_r F_k, \eta_{\eta} = F_r^2 = \sum_{N_x/2}^{N_x/2} \sum_{-N_y/2}^{N_y/2} \eta_k e^{-i k r}, \]

here \(N_x, N_y\) — are number of Fourier modes in \(x\) and \(y\) directions.

As a result of simulation we observed \[12\] \[13\] formation of both direct and inverse cascades (Fig. 1 solid line). Average steepness was equal to \(\sqrt{\langle \nabla \eta^2 \rangle} = 0.14\.

\[\text{What is important, development of inverse cascade spectrum was arrested by discreteness of wavenumbers.}\]
grid in agreement with [10,18,24,25]. Then large scale condensate started to form. The mechanism of condensate formation is the following. We have a flux of wave action (number of waves) from the pumping to the large scale region. This flux is due to nonlinear resonant interaction of waves. In [10] it was shown, that on a discrete grid of wavenumbers, which is typical for both finite experimental wave tanks and computer simulations, resonance conditions are never fulfilled exactly. What makes it possible for them to exist is the finite width of the resonant curve due to nonlinear frequency shift. As a result, this thick resonant curve covers some knots of the wavenumbers grid [18]. The nonlinear frequency shift is proportional to the matrix element (coupling coefficient) of interaction of waves, which is homogeneous function of the order 3 (with change of \(k\) it behaves as \(k^3\)). Which means that we have good coverage of the grid knots in high wavenumbers, characteristic for the direct cascade, and worse and worse situation as we move toward the origin of the \(k\)-plane. So at some stage the resonant interactions turn off due to discreteness of the wavenumbers grid and flux cannot propagate further. At the same time, new wave are still brought to the wavenumbers grid and flux cannot propagate further. The direct cascade is too short to exclude possible influence of pumping and condensate, we can roughly estimate its slope as \(k^{-3.5}\) [12], which is slightly less than the prediction of the theory of weak turbulence \(k^{-23/6} \sim k^{-3.83}\). Resent findings [14] with significantly longer inertial interval for the inverse cascade, support this result and propose the slope \(k^{-3.15}\).

Let us discuss possible reason for this deviation from the theory of weak turbulence. The direct cascade of energy and inverse cascade of wave action correspond two Kolmogorov-type solutions of the Hasselmann kinetic equation for waves [20]. These solutions were derived by Zakharov in the middle of sixties under a few reasonable assumptions: media is isotropic with respect to rotations, dispersion relation is a power-like function \(\omega_k k^d\), matrix element of nonlinear interaction (nonlinear coupling coefficient) for waves is a homogeneous function \(T(\varepsilon k_1, \varepsilon k_2, \varepsilon k_3, \varepsilon k_4) = \varepsilon^3 T(k_1, k_2, k_3, k_4)\). Under these assumptions Zakharov [12,26,28] obtained Kolmogorov-like solutions corresponding to fluxes of two integrals of motion (energy and wave action or number of waves):

\[
\begin{align*}
    n_k^{(1)} &= C_1 P^{1/3} k^{-\frac{23}{24} - d}, \quad n_k^{(2)} = C_2 Q^{1/3} k^{-\frac{23}{24} - d}. \quad (5)
\end{align*}
\]

Here \(d\) is a spatial dimension (\(d = 2\) in our case). In the case of gravity waves on a deep water \(\omega = \sqrt{gk}\) (\(\alpha = 1/2\)) and, apparently, \(\beta = 3\). As a result one can get:

\[
\begin{align*}
    n_k^{(1)} &= C_1 P^{1/3} k^{-4}, \quad n_k^{(2)} = C_2 Q^{1/3} k^{-23/6}. \quad (6)
\end{align*}
\]

The first spectrum \(n_k^{(1)}\) corresponds to the direct cascade. In this work we are more interested in the second spectrum \(n_k^{(2)}\) describes to inverse cascade, corresponding to flux of number of waves (or wave action) from small scales (pumping) to larger scales. As one can see, inverse cascade spectrum formula directly depends on \(\alpha\), the power of the dispersion relation. So it would be helpful for understanding of the situation to measure directly the dispersion relation of waves. How one can do this measurement?

In the case of linear plane wave, for harmonic \(a_k\) will have just rotation of phase with constant amplitude \(a_k(t) = A_k \exp(-i\omega_k t)\), with circular frequency corresponding the linear dispersion relation \(\omega(\vec{k}) = \sqrt{gk}\). So if one would write down the \(a_k(t)\) as a function on time and then calculate Fourier transform from time domain to the frequency domain, the result of such transformation will be \(\delta\)-function in \(\omega\)-space.

In the case of weak nonlinearity this rotation is the fastest process, but amplitude \(A_k(t)\) will be already slow
function on time due to weakly nonlinear interaction of waves. Let us investigate how the dispersion relation is influenced by the nonlinear interactions in the system. For this we record $a_2(t)$ for different values of $k$ and then calculate a Fourier transform on time, which leads to the function $a_2(\omega)$. Because we have isotropic with respect to angle situation, we can limit ourselves with harmonics on any ray starting at the origin of the $k$-plane. In our numerical experiment we recorded every other harmonics on the $k_x$-axis, from $k = (2; 0)$ till $k = (30; 0)$ till $k = (180; 0)$ (for further wavenumbers the plot becomes extremely noisy, also it is already range of artificial dissipation) and calculated a Fourier transform. The resulting surface $|a_2(k)|$ is represented in Fig. 2. The observed sidebands are due to nonlinear interaction with condensate. Although the nonlinear process supposed to be weak, the fact that condensate scale, influence on the dispersion is almost negligible, although the central line is slightly shifted by the nonlinear frequency shift.

![Fig. 2](Color online) Surface $|a_2(\omega)|$. Normed to the maximum for every given value of $k$. Bright vertical line – pumping region. Sidebands, corresponding to the interaction with condensate, are clearly visible. Sidebands estimations: solid line (black) – $\omega_{k,-k_0} = \omega_{k,k_0}$; solid line (red) – $\omega_{k,-k_0} = \omega_{k-k_0} + \omega_{k_0}$; dashed-dotted line (olive) – $\omega_{k,-k_0} = \omega_{k+k_0} + \omega_{k_0}$; dotted line (brown) – $\omega_{k,-k_0} = \omega_{k-k_0} - \omega_{k_0}$; line with short dashes (blue) – linear dispersion relation $\omega_k = \sqrt{gk}$. The observed sidebands are due to nonlinear interaction with condensate. Although the nonlinear process supposed to be weak, the fact that condensate scale, influence on the dispersion is almost negligible, although the central line is slightly shifted by the nonlinear frequency shift.

![Fig. 3](Color online) Sections of the surface $|a_2(\omega)|$. Solid line (red): spectral line for $k = (10; 0)$; dotted vertical lines of both colors correspond to linear dispersion relation $\omega_k = \sqrt{gk}$.

To summarize, we performed a direct numerical sim-
ulation of the isotropic turbulence of the surface gravity waves. Currently, the inverse cascade slope, observed in numerical simulations, is different from theoretical predictions of the wave turbulence theory. In order to investigate possible reasons we measured the dispersion relation for waves in the presence of condensate. It was shown that in the region of inverse cascade sidebands are of the same order of magnitude as the central line corresponding to the linear dispersion relation. It means that in the vicinity of condensate we have to take the influence of the condensate into account. One of the possible ways is to use the Bogolyubov transformation in order to calculate the augmented dispersion relation, in the same style as it was done for phonons in liquid Helium. This is problem for future work, because in our case situation is much more difficult, since condensate is located on the finite $k_c$ and coupling coefficient for gravity waves is immensely more complex. We hope that our current result can be one of the building blocks for the theory of inverse cascade in the presence of condensate.

The author would like to thank Yu. V. Lvov and G. E. Falkovich for enlightening discussions. The idea about the Bogolyubov transformation was proposed by V. V. Lebedev and I. V. Kolokolov during presentation of this work on the Scientific Council of the Landau Institute. The author was partially supported by the NSF grant 1131791 and grant NSh-6885.2010.2.

Also the author would like to thank developers of FFTW [29] and the whole GNU project [30] for developing, and supporting this useful and free software.
