Abstract

Introduction: Antiphospholipid antibodies (aPL) affect atherogenesis and may cause thromboembolism in systemic lupus erythematosus (SLE) and coronary artery disease (CAD). Intensive treatment with statins may reduce inflammation and decrease the number of thrombotic events. That may explain the beneficial effect of statin therapy in SLE and CAD. This study was established to investigate the influence of statin treatment on aPL antibody levels and selected endothelial dysfunction markers in CAD and SLE patients.

Material and methods: Fifty-eight patients – 40 after coronary revascularization (age 38.9 (27–46), 35 males) and 18 with clinically stable SLE (age 38.8 (18–62), 1 male) – were enrolled in the study. In both groups intensive atorvastatin treatment was administered. At baseline and after 1 year of follow-up serology tests were performed: anticardiolipin antibodies (aCL), anti-β2 glycoprotein I (aβ2GPI), lupus anticoagulant (LA), C-reactive protein (CRP), soluble form of intracellular adhesion molecule-1 (sICAM-1), vWF:Ag.

Results: Coronary artery disease patients in 1 year follow-up revealed a decrease of aβ2GPI IgG and CRP. There was a significant increase in aCL IgG, sICAM-1 and vWF:Ag. In SLE patients aPL levels showed no significant reduction after treatment.

Conclusions: In clinically stable patients IgM and IgG class aβ2GPI levels are higher in CAD than in SLE, whereas IgG class aCL levels are lower. Statin treatment decreases the CRP level in both SLE and CAD patients, while decreasing the aβ2GPI IgG level only in CAD patients.

Key words: rheumatic diseases, atherosclerosis, antiphospholipid syndrome, myocardial ischemia.

Introduction

Antiphospholipid antibodies (aPL) constitute a heterogenous family of immunoglobulins reacting with a variety of plasma proteins. Among them
lupus anticoagulant (LA), anticardiolipin antibodies (aCL), and anti-β2 glycoprotein I (β2GPI) are those best known. Their elevated plasma level is critical for antiphospholipid syndrome diagnosis [1] and was included in systemic lupus erythematosus (SLE) diagnostic criteria as well [2]. There is some evidence that in coronary artery disease (CAD) patients aPL remain within the normal range but are significantly higher than in healthy individuals [3, 4]. Their prothrombotic activity in venous and arterial thrombosis was well documented [5], but their action in atherosclerosis progression is still not clear [6]. Robust evidence for the impact of aPL on atherosclerosis progression comes from peripheral arterial disease (PAD) studies. On the other hand, in CAD aPL are associated with the occurrence of myocardial infarction (MI) rather than CAD progression itself [6].

Among endothelial dysfunction markers (EDM) C-reactive protein (CRP) is highly associated with intensification of inflammation, with thrombosis promotion [7] and thus with coronary plaque instability [8]. Although CRP is not recommended for routine cardiovascular (CV) risk refinement assessment [9], it is sensitive and it reflects different mechanisms of atherosclerosis [7]. Intracellular adhesion molecule-1 (ICAM-1) is a glycoprotein facilitating diapedesis across the vessel wall and, similarly to CRP, correlates with endothelial activation and damage [7]. sICAM-1 is a soluble form of ICAM-1 and is regulated by the same mechanisms as ICAM-1 [10]. Von Willebrand factor (vWF) also reflects endothelial injury and plays a relevant role in platelet activation and aggregation [11]. Because it is a nonspecific marker its role may be limited to accessory function with other biomarkers. Despite the fact that those biomarkers may be used to assess atherosclerosis activity in CAD patients, they probably might be also useful in monitoring atherosclerosis in SLE patients.

Statins’ role is substantial in CAD treatment and has been well described in numerous studies [12, 13]. The major, dose-dependent effect of treatment is low-density lipoprotein (LDL) cholesterol lowering through inhibiting hepatic cholesterol synthesis. Statins also decrease triglyceride serum level and increase high-density lipoprotein (HDL) cholesterol serum level, but this effect is achievable with higher doses. Intensive treatment may reduce the volume of coronary artery atherosclerotic plaques and change their composition [13, 14]. Statin pleiotropic action is based on isoprenoid inhibition and influences numerous signaling pathways. In vivo studies showed an effect on nitric oxide synthesis, production of proinflammatory cytokines, vasoconstrictive factors and reactivity of platelets [15–18]. These may result in a reduction of inflammation [19, 20] and a decrease in the thrombosis occurrence [21].

In SLE, statin treatment is still debated. Although it has been confirmed that statins reduce the risk of thrombosis [22], may have a similar effect on atherosclerosis as in CAD restraining atherosclerotic plaque progression [23] and reduce CV risk [24], they are not used routinely in current pharmacotherapy [25]. Even though currently CAD and atherosclerosis are the leading causes of death in SLE, statin treatment is restricted to patients with known hypercholesterolemia and/or symptomatic CAD [26].

Our objective was to investigate the influence of statin treatment on autoimmunity assessed by aPL levels and endothelial damage/activation measured by sICAM-1 and vWF levels in young CAD or SLE patients, as two models of autoimmune-dependent atherosclerosis.

**Material and methods**

**Patients**

Fifty-eight patients were enrolled in the study. Forty patients (mean age: 38.9 ±4.6, 35 male) with confirmed angiographically CAD underwent a myocardial revascularization procedure in the Department of Cardiac and Vascular Diseases, Jagiellonian University, John Paul II Hospital in Krakow between January 2012 and December 2014. Among 18 patients with SLE (mean age: 38.8 ±11.9, 1 male) treated in the Department of Internal Medicine, Jagiellonian University, Krakow (January 2010 – December 2014) 11 were treated with standard pharmacotherapy (9 on methylprednisolone ≤ 4 mg/day), 1 on chloroquine derivate, 1 on azathioprine). Precise study group characteristics is depicted in Table I.

After obtaining written, informed consent, conforming to the International Declaration of Helsinki, patients were enrolled in the study. Exclusion criteria in the CAD group were: age at diagnosis above 45 years old or severe organ failure (including renal disease – grade 4 and 5 KIDGO, heart failure NYHA IV, respiratory failure). Patients with known autoimmune disease were excluded as well. Subjects with SLE were enrolled only if in stable clinical condition and without known other autoimmune disease, including antiphospholipid syndrome (APS). A documented period of at least 3 months of steady doses of immunosuppressants was obligatory. Exclusion criteria concerning organ failure were the same as in the CAD group. Systemic lupus erythematosus activity index (SLEDAI) score at baseline (BL) was within the range 3–20, median 4. After a year the median SLEDAI score value remained at the same level (4) but the range of results was different (0–20). In...
IgM) was used to measure \( \beta_2 \text{GPI} \). Cut-off values for aPL were as follows: aCL IgG 10 GPL, aCL IgM 20 MPL, \( \beta_2 \text{GPI} \) IgG 20 SGU, \( \beta_2 \text{GPI} \) IgM 20 SGU, and reflected the 99th percentile of the healthy population. Detection of LA was performed according to three-step analysis recommended by the International Society on Thrombosis and Haemostasis (ISTH). Only a negative test of LA was considered normal.

Soluble form of intracellular adhesion molecule-1 levels were assessed with a quantitative immunoenzymatic assay (ELISA) kit (R&D, BIOKOM, UK) in blood serum. Normal values for sICAM-1 were in the range 98.8–320 ng/ml. Measurements of vWF:Ag were done in plasma with commercial ELISA kit (Hyphen, Austria), normal values: 50–160%. C-reactive protein was assessed in serum, with the commercial analyzer BN II System and dedicated reagents (Siemens, Germany). Normal values for CRP: 0–5 mg/l.

Samples in the CAD group at BL were taken at least 4 weeks after the coronary procedure (mean: 15.5 weeks). Time between samples collection, BL and follow-up, was at least 12 months (mean: 74 weeks). Samples in the SLE group were taken within 1 week after enrollment of a patient in the study. Time between samples collection (BL to follow-up) was at least 12 months (mean: 63 weeks). Before laboratory analysis was per-

### Table I. Study subgroup characteristics

| Parameter | CAD group (n = 40) | SLE group (n = 18) |
|-----------|--------------------|--------------------|
| Age [years] mean ± SD | 38.9 ±4.6 | 38.8 ±11.9 |
| Male sex, n (%) | 35 (88) | 1 (5.6) |
| Conventional risk factors, n (%): | | |
| Hypercholesterolemia | 37 (93) | 0 (0) |
| Nicotinism | 26 (65) | 1 (5.6) |
| Obesity | 13 (33) | 0 (0) |
| Arterial hypertension | 28 (70) | 2 (11.1) |
| Diabetes mellitus type 2 | 4 (10) | 0 (0) |
| First manifestation of CAD: | | |
| Age at first manifestation, [years] mean ± SD | 38.0 ±5.0 | N/A |
| Acute myocardial infarction, n (%) | 31 (76) | N/A |
| ST-elevation myocardial infarction, n (%) | 23 (58) | N/A |
| Stable CAD, n (%) | 8 (20) | 0 (0) |
| History of PCI, n (%) | 37 (92) | 0 (0) |
| History of CABG, n (%) | 6 (15) | 0 (0) |
| CAD optimal medical therapy only, n (%) | 1 (2) | N/A |

CAD – coronary artery disease, SLE – systemic lupus erythematosus, PCI – percutaneous coronary intervention, CABG – coronary artery bypass grafting.
Influence of statin therapy on antiphospholipid antibodies and endothelial dysfunction in young patients with coronary artery disease or systemic lupus erythematosus

Table II. Inter-group comparison (CAD vs. SLE): aPL, sICAM-1, vWF:Ag, CRP serum levels – baseline and follow-up

| Parameter                  | CAD      | SLE      | P-value |
|----------------------------|----------|----------|---------|
| **Baseline:**              |          |          |         |
| LA, n (%)                  | 0 (0)    | 2 (11)   | 0.032   |
| aCL IgM [MPL], median (range) | 6.8 (1.2–26.4) | 9.6 (3.9–34.9) | 0.107   |
| aCL IgG [GPL], median (range) | 3.6 (1.9–14.0) | 9.9 (1.8–90.2) | < 0.001 |
| αβ2GPI IgM [SGU], median (range) | 3.0 (1.4–11.7) | 1.0 (0.1–52.7) | < 0.001 |
| αβ2GPI IgG [SGU], median (range) | 4.0 (0.6–17.5) | 1.4 (0.2–54.0) | < 0.001 |
| sICAM-1 [ng/ml], median (range) | 275.5 (179.2–765.3) | 273.76 (184.44–335.37) | 0.358   |
| vWF:Ag (%), median (range) | 115.8 (49.4–188.5) | 132.94 (79.09–241.95) | 0.048   |
| CRP [mg/l], median (range)  | 2.96 (0.17–37.5) | 3.17 (0.27–22.4) | 0.806   |
| **12-month follow-up:**   |          |          |         |
| LA, n (%)                  | 0 (0)    | 2 (11)   | 0.032   |
| aCL IgM [MPL], median (range) | 6.1 (1.0–16.4) | 6.6 (2.4–157.7) | 0.253   |
| aCL IgG [GPL], median (range) | 6.0 (1.4–17.0) | 9.0 (2.1–107.9) | 0.097   |
| αβ2GPI IgM [SGU], median (range) | 2.9 (1.8–11.7) | 1.2 (0.6–3.1) | < 0.001 |
| αβ2GPI IgG [SGU], median (range) | 0.7 (0.5–4.6) | 0.91 (0.3–3.0) | 0.529   |
| sICAM-1 [ng/ml], median (range) | 310.8 (203.9–614.9) | 263.65 (195.12–560.09) | 0.023   |
| vWF:Ag (%), median (range) | 136.4 (50.3–183.5) | 145.68 (86.37–271.47) | 0.302   |
| CRP [mg/l], median (range)  | 1.07 (0.17–13.9) | 0.94 (0.16–8.22) | 0.992   |

Statistics analysis

Statistical analysis was performed using Statistica 10, Sigma Software. Numerical data were presented using mean value ± standard deviation (SD) or median value and range (min-max) in case of lack of normal distribution. Categorical variables were presented as a proportion. Differences in continuous variables were assessed with the Wilcoxon signed-rank test in case of repeated measurements or if no normal distribution (Student’s t-test in case of normal distribution). Categorical variables were compared using the χ² test. The p-value for statistical significance was established at < 0.05.

Results

In the whole study population none of the patients fulfilled revised criteria for APS [1] within the observational period. At BL, αβ2GPI IgG and IgM were higher in CAD patients, whereas aCL IgG and vWF:Ag were high-

Table III. Inter-group comparison (CAD vs. SLE): aPL positivity – baseline and follow-up

| Parameter                  | CAD      | SLE      | P-value |
|----------------------------|----------|----------|---------|
| **Baseline, n (%):**       |          |          |         |
| LA                         | 0 (0)    | 2 (11)   | 0.032   |
| aCL IgM                    | 2 (5)    | 4 (22)   | 0.046   |
| aCL IgG                    | 4 (10)   | 9 (50)   | 0.001   |
| αβ2GPI IgM                 | 0 (0)    | 1 (6)    | 0.133   |
| αβ2GPI IgG                 | 0 (0)    | 1 (6)    | 0.133   |
| **12-month follow-up, n (%):** |          |          |         |
| LA                         | 0 (0)    | 2 (11)   | 0.032   |
| aCL IgM                    | 0 (0)    | 2 (11)   | 0.032   |

| αβ2GPI IgM                 | 0 (0)    | 1 (6)    | 0.133   |
| αβ2GPI IgG                 | 0 (0)    | 1 (6)    | 0.133   |
SLE patients at BL, as well as at 1-year follow-up (Table III). Only 2 patients exceeded the level of 40 GPL and/or SGU (aCL, αβ2GPI) during the whole study period, both in the SLE group.

After 12 months of treatment with atorvastatin in the CAD study subgroup there was a significant decrease of αβ2GPI IgG and of CRP serum levels. There was also a statistically significant increase in aCL IgG, sICAM-1 and vWF:Ag (Table IV). Contrary to these changes, in the SLE subgroup there was a decrease in CRP level only, whereas sICAM-1, vWF:Ag and aPL remained at similar levels.

### Discussion

Although CAD in young patients in the majority of cases is connected with conventional risk factors [27], in approximately 20% it may be a result of coronary abnormalities and non-traditional risk factors such as connective tissue disorders, drugs and autoimmunity [28]. Some studies show that aPL serum levels are higher in young CAD patients than in healthy controls [3, 4]. In SLE patients autoimmunity is confirmed to contribute to atherosclerosis progression not only due to increased risk of thrombosis, but also by plaque progression [5, 23].

This paper shows that BL aPL, although within the normal range, are higher in the CAD than in the SLE group. This seems unusual, as aPL are a part of SLE diagnostic criteria [2]. Moreover, it seems that atorvastatin has a weaker effect on aPL in SLE compared to CAD, as there was no decrease of αβ2GPI in the SLE group. Initial measurements were done in treated, immunologically stable SLE patients (median SLEDAI score 4), which may be relevant in the context of aPL level. Recently Serrano et al. [29] reported that immunosuppression may reduce αβ2GPI: in post-renal transplant patients elevated αβ2GPI IgA level before surgery was significantly decreased after immunosuppressant introduction.

The main finding is that statin decreases αβ2GPI IgG in CAD. Among aPL, αβ2GPI are more often, as compared to aCL/ LA, associated with CAD and may reflect disease severity and future outcomes [30]. Moreover, αβ2GPI serum level elevation was proven to influence atherosclerosis plaque progression and subclinical atherosclerosis via T cell response [31] and promote oxLDL accumulation in macrophages [6] apart from its thrombotic activity. Clinical manifestation of elevated αβ2GPI is associated with future revascularization

### Table IV. Comparison within CAD and SLE groups: aPL, sICAM-1, vWF:Ag, CRP serum levels – baseline and follow-up

| Parameter | Baseline | 1 year follow-up | P-value |
|-----------|----------|------------------|---------|
| **CAD group:** | | | |
| LA, n (%) | 0 (0) | 0 (0) | NA |
| aCL IgM [MPL], median (range) | 6.8 (1.2–26.4) | 6.1 (1.0–16.4) | 0.051 |
| aCL IgG [GPL], median (range) | 3.6 (1.9–14.0) | 6.0 (1.4–17.0) | 0.001 |
| aβ2GPI IgM [SGU], median (range) | 3.0 (1.4–11.7) | 2.9 (1.8–11.7) | 0.665 |
| aβ2GPI IgG [SGU], median (range) | 4.0 (0.6–17.5) | 0.7 (0.5–4.6) | < 0.001 |
| sICAM-1 [ng/ml], median (range) | 275.5 (179.2–765.3) | 310.8 (203.9–614.9) | 0.007 |
| vWF:Ag (%), median (range) | 115.8 (49.4–188.5) | 136.4 (50.3–183.5) | < 0.001 |
| CRP [mg/l], median (range) | 2.96 (0.17–37.5) | 1.07 (0.17–13.9) | < 0.001 |
| **SLE group:** | | | |
| LA, n (%) | 2 (11) | 2 (11) | 1 |
| aCL IgM [MPL], median (range) | 9.6 (3.9–34.9) | 6.6 (2.4–157.7) | 0.691 |
| aCL IgG [GPL], median (range) | 9.9 (1.8–90.2) | 9.0 (2.1–107.9) | 0.496 |
| aβ2GPI IgM [SGU], median (range) | 1.0 (0.1–52.7) | 1.2 (0.6–3.1) | 0.091 |
| aβ2GPI IgG [SGU], median (range) | 1.4 (0.2–54.0) | 0.91 (0.3–3.0) | 0.534 |
| sICAM-1 [ng/ml], median (range) | 273.76 (184.44–335.37) | 263.65 (195.12–560.09) | 0.155 |
| vWF:Ag (%), median (range) | 132.94 (79.09–241.95) | 145.68 (86.37–271.47) | 0.754 |
| CRP [mg/l], median (range) | 3.17 (0.27–22.4) | 0.94 (0.16–8.22) | 0.016 |

CAD – coronary artery disease, SLE – systemic lupus erythematosus, aPL – antiphospholipid antibodies, sICAM-1 – soluble form of intracellular adhesion molecule-1, CRP – C-reactive protein.
