The Effect of Metadherin on NF-κB Activation and Downstream Genes in Ovarian Cancer

Chunhong Rong1, Yanfen Shi2, Jun Huang1, Xinyue Wang3, Risa Shimizu4, Yuki Mori4, Akiko Murai5, and Jing Liang6

Abstract
Ovarian cancer (OC) is the most aggressive gynecological cancer. Even with the advances in detection and therapeutics, it still remains clinically challenging and there is a pressing need to identify novel therapeutic strategies. In searching for rational molecular targets, we identified metadherin (MTDH), a multifunctional gene associated with several tumor types but previously unrecognized in OC. In this study, we found the MTDH is overexpressed in OC tissues. Through in vitro assays with overexpression cells, we characterized the role of MTDH. We confirmed MTDH stable overexpression significantly increased the expression of TNF-α, IL-6, IL-8, IL-10, and IL-1β. Interestingly, NF-kappa-B (NF-κB) and MTDH were found in a feed-forward loop motif. Thus, our findings support the notion that the MTDH and NF-κB signaling network contributes to OC traits. MTDH represents a new OC-associated gene that can contribute to insights of OC biology and suggests other treatment strategies.

Keywords
metadherin, NF-κB, chronic inflammation, ovarian cancer

Introduction
Ovarian cancer (OC) is the leading cause of gynecological-related deaths and the fifth leading cause of cancer mortality seriously threatening females’ lives and health worldwide. Extensive efforts have been made to improve treatment; however, the number of cases is increasing worldwide. Thus, there is a pressing need to identify novel therapeutic strategies.

Metadherin (MTDH) is alternatively known as astrocyte elevated gene-2. MTDH is a membrane protein that regulates the homing of tumor cells to the lung endothelium and is a lysine-rich protein associated with tight junctions in prostate epithelial cells. It is a universally important cancer-associated gene. It has been validated in diverse malignancies, such as breast, lung, esophageal, B-cell lymphoma, brain tumors, gynecologic cancers, and malignant pleural mesothelioma (MPM). Additionally, MTDH has been identified as the direct target of miR-182-5p contributing to the inhibition of proliferation and metastasis in colorectal cancer. However, the role of MTDH is still incompletely understood in OC.

The transcription factor NF-κB plays a key role in stress response due to environmental stimuli by regulating genes involved in proliferation, apoptosis, differentiation, inflammation, and immune system regulation. In nonstress conditions, NF-κB is sequestered in the cytoplasm by its repressor IκBα. Because of its importance to many biological processes, NF-κB activation and activity are tightly regulated by a battery of endogenous mechanisms. Aberrant
NF-κB activation contributes to the development of various autoimmune, inflammatory, and malignant disorders. Thus, inhibiting NF-κB signaling has potential therapeutic applications in cancer. A previous study reported the activation of EMT in colorectal cancer by MTDH/NF-κB p65 pathway\(^1\). However, the role of MTDH/NF-κB p65 pathway is still unclear in OC.

In this study, we explored the expression of MTDH, inflammatory cytokines, and chemokines in OC. In particular, we uncovered a feed-forward regulatory mechanism of MTDH/NF-κB signaling pathway. Our results contribute to insights of OC biology and suggest other treatment strategies in OC.

**Materials and Methods**

**Tissues and Cell Culture**

The human ovarian cancer cell line, SKOV-3, was purchased from ATCC (Manassas, VA, USA). Cells were maintained in RPMI 1640 (Gibco Laboratories, Carlsbad, CA, USA) enriched with 10% fetal bovine serum (Sigma-Aldrich, St Louis, MO, USA), 100 U/ml penicillin, and 100 mg/ml streptomycin (Sigma-Aldrich). Cells were cultured at 37 °C with 5% CO\(_2\). SKOV-3 cells were subcultured at 90% confluence.

Study OC tissues were obtained from 18 patients diagnosed in the Department of Gynecology and Obstetrics of China–Japan Friendship Hospital (Beijing, China), between August 2018 and December 2018. All the specimens were reviewed and verified by pathologists and immediately frozen in liquid nitrogen. All subjects gave their informed consent for inclusion before they participated in the study. All experimental protocols were approved by the Ethics Committee of China–Japan Friendship Hospital.

**Quantitative Real-Time PCR**

We extracted total RNA from 3 × 10\(^6\) of cells following the mirVana™ miRNA isolation kit (Ambion, Austin, TX, USA) protocol. Reverse transcription was done using the high-capacity RNA-to-cDNA kit (Thermo Fisher Scientific, Waltham, MA, USA) after removal of residual genomic DNA by DNase I (Invitrogen, Carlsbad, CA, USA).

Specific gene quantitation was determined by TaqMan analysis using QuantStudio 6 Flex PCR system (Thermo Fisher Scientific). β-Actin gene was used as an endogenous housekeeping gene for normalization. Specific gene expression probes including TNF-α, IL-6, IL-8, IL-10, and IL-1β were commercially available from Applied Biosystems (Foster City, CA, USA). All independent PCR-based reactions were performed in triplicate.

The relative expression ratio of each gene was calculated with the comparative CT method (ΔΔCt method)\(^12\).

**MTDH Overexpression**

In order to elucidate the role of MTDH in vitro, we used the lentiviral system (Applied Biological Materials, Montreal, Canada) to stably overexpress MTDH (MTDH-OE) and its negative control vector (Ctrl-OE) in SKOV-3 cells. The overexpression was according to the manufacturer’s instructions.

**Western Blotting**

For each sample, total protein lysis was separated on 4%–15% precast gels (Bio-Rad, Richmond, CA, USA) and then blotted onto nitrocellulose paper (Bio-Rad). Membranes were blocked with 5% dried nonfat milk powder in TBST for 1 h and incubated with primary antibodies overnight at 4 °C. After being washed with TBST three times, the membranes were incubated with the goat anti-rabbit horseradish peroxidase (HRP)-conjugated secondary antibody (1:2,000; cat. no. STAR124P; Bio-Rad) or goat anti-mouse HRP-conjugated secondary antibody (1:5,000; cat. no. STAR207P; Bio-Rad) for 2 h at room temperature. The band signals of target proteins were visualized using an enhanced chemiluminescence kit (Pierce, Minneapolis, MN, USA). All the experiments were repeated three times. In order to avoid possible problems related to incomplete stripping, all the results are from separate blots.

The primary antibodies are anti-MTDH (1:500, Millipore, Bedford, MA, USA), p-p65 (1:1,000, Cell Signaling Technologies, Beverly, MA, USA), p65 (1:1,000, Cell Signaling Technologies), and β-actin (Sigma-Aldrich).

**Chromatin Immunoprecipitation**

Chromatin immunoprecipitation (ChIP) was used to verify NF-κB (RELA) interaction with the promoter region of MTDH. SKOV-3 and TOV-112D cell lines were prepared using the Magna ChIP A-Chromatin Immunoprecipitation Kit (Millipore, Billerica, MA, USA). DNA was eluted and purified from complexes, followed by SYBR PCR amplification of three putative binding sites of RELA within the MTDH promoter\(^8\). Immune complexes formed with nonspecific IgG were a negative control, while 1kBz promoter primers (manufacturer’s kit) were a positive control. Primer pairs flanking these binding sites were used following the method previously described\(^8\).

**Enzyme-Linked Immunosorbent Assay**

Culture medium was centrifuged at 1,000 rpm for 5 min at 4 °C to remove residual cells, immediately after collection. The supernatant was harvested and stored at −20 °C for subsequent analysis. Concentrations of TNF-α, IL-6, IL-8, IL-10, and IL-1β in culture media were assayed using relative enzyme-linked immunosorbent assay (ELISA) kits (Abcam, Cambridge, MA, USA), according to the manufacturers’ instructions. All samples were assayed in duplicate. Cytokine concentrations are expressed as pg/ml based on relevant standard curves.
Statistics

Means and standard errors (SEs) were calculated from numerical data. Fold change(s) indicate the difference between experimental and control samples. Bar graphs depict the mean ± SE for a specific experimental run. SPSS Statistics 17 (SPSS Software, Chicago, IL, USA) was used for calculations. Two-tailed, unpaired Student’s t test assessed significance between two conditions. One-way analysis of variance test followed by Tukey’s comparison for multiple groups compared the significance of differences between the means of groups. Two-tailed P-value < 0.05 was considered significant.

Results

MTDH Is Upregulated in Ovarian Cancer Tissues

MTDH was reported to be overexpressed in OC13. To decipher the underlying molecular biology and function of MTDH in OC, we first examined the mRNA expression levels of MTDH in the 16 ovarian cancer tissues and the paired nontumorous tissues with Taqman quantitative real-time PCR. Consistently, MTDH showed much higher mRNA level in the OC tissues compared to the paired nontumorous tissues (Fig. 1). These results suggest that MTDH overexpression in OC may be attributed to OC traits.

MTDH Overexpression Enhances Expression of TNF-α, IL-6, IL-8, IL-10, and IL-1β

Chronic inflammatory conditions contribute to maintaining several signaling pathways that could represent plausible mechanism(s) for MTDH overexpression8. We subsequently investigated the inflammatory cytokine and chemokine expressions in OC. As seen in Figure 2A, TNF-α, IL-6, IL-8, IL-10, and IL-1β mRNA expressions were greatly augmented in OC tissues than the paired nontumorous tissues. In order to explore whether MTDH regulates inflammatory cytokine and chemokine expressions in OC, we stably overexpressed MTDH in SKOV-3 cells (Fig. 2B, C). Subsequently, the MTDH overexpression was investigated to significantly augment TNF-α, IL-6, IL-8, IL-10, and IL-1β mRNA expression after 24 h of TNF-α challenge (Fig. 2D).

Cytokine protein production in culture media of SKOV-3 cells was quantified by ELISA. After 24 h of TNF-α treatment, we observed a significant increase in TNF-α, IL-6, IL-8, IL-10, and IL-1β proteins in the culture media compared with the levels of these cytokines in the Ctrl-OE group (Fig. 2E).

Regulation of MTDH and NF-κB in Ovarian Cancer

TNF-α, IL-6, IL-8, IL-10, and IL-1β are transcriptionally controlled by NF-κB14. It has also been reported that MTDH overexpression contributes to the induction of NF-κB via secondary positive feedback signaling8,15. In this study, to elucidate the underlying molecular network of MTDH and inflammatory condition, we subsequently investigated whether MTDH contributes to the induction of NF-κB. As shown in Figure 3A, MTDH overexpression greatly increased the mRNA level and protein expression of phosphor-p65 compared with the Ctrl-OE group.

Discussion

The normal physiologic role of MTDH still remains elusive16. MTDH acts as a transcriptional cofactor via a nuclear homing domain17. Currently, MTDH has been shown as a critical regulator in a variety of cancers, such as lung cancer, hepatocellular carcinoma, and gastric cancer18–20. The reason is because MTDH can regulate multiple signaling pathways and expression levels of related genes to affect the behavior of tumors, such as NF-κB, PI3K/AKT/MAPK, and Wnt/β-catenin15. Through these signaling pathways, MTDH can also affect the cellular activities including proliferation, angiogenesis, invasion, metastasis, and drug resistance. Despite an extensive literature regarding the multiple
Figure 2. MTDH enhances mRNA and protein expression of TNF-α, IL-6, IL-8, IL-10, and IL-1β. (A) TNF-α, IL-6, IL-8, IL-10, and IL-1β mRNA level is upregulated in OC tissues. mRNA levels were detected by qRT-PCR in 16 paired OC tissues and paired non-tumorous tissues. *P < 0.05 vs non-tumorous tissues; (B) MTDH mRNA level is significantly higher after MTDH overexpression. *P < 0.05 vs Ctrl-OE. Results are mean ± SE (n = 3). (C) MTDH protein expression is significantly higher after MTDH overexpression. (D) After cells stably overexpressed MTDH, cells were stimulated or not with TNF-α (10 ng/ml) for 24 h. The mRNA expression of TNF-α, IL-6, IL-8, IL-10, and IL-1β was analyzed by qRT-PCR. The expression of each gene was normalized to the average of nonstimulated cells. *P < 0.05 vs nonstimulated cells; ^P < 0.05 vs Ctrl-OE. Results are mean ± SE (n = 3). (E) The protein levels of TNF-α, IL-6, IL-8, IL-10, and IL-1β in the culture media were assayed with a specific ELISA. *P < 0.05 vs nonstimulated cells; ^P < 0.05 vs Ctrl-OE. Results are mean ± SE (n = 3). Ctrl: control; ELISA: enzyme-linked immunosorbent assay; MTDH: metadherin; OC: ovarian cancer; OE: overexpression; qRT-PCR: quantitative real-time polymerase chain reaction.
functions of MTDH, the precise function of MTDH in OC has not been investigated in detail.

NF-κB is a transcription factor that controls various important genes in many critical physiological responses such as inflammatory responses, proliferation, differentiation, cell adhesion, and apoptosis. Because of its importance to many biological processes, NF-κB activation and activity are tightly regulated by a battery of endogenous mechanisms. The aberrant NF-κB activation contributes to the development of various autoimmune, inflammatory, and malignant disorders including malignant tumors such as MPM and squamous cell carcinoma. The activation of NF-κB signaling by MTDH has also been reported in hepatocellular carcinoma. What is more, MTDH was reported as a prognostic apoptosis modulator in mesothelioma induced via NF-κB-mediated signaling. However, the underlying mechanism and precise function of MTDH/NF-κB signaling still remains unclear.

In this study, we verified that MTDH is upregulated in the OC tissues compared to the paired non-tumorous tissues. Subsequently, we also found TNF-α, IL-6, IL-8, IL-10, and IL-1β mRNA expressions were greatly augmented in OC tissues than the paired non-tumorous tissues. Next, MTDH overexpression greatly increased the mRNA level and protein expression of phosphor-p65 compared with the Ctrl-OE group. Using ChIP analysis, we also validated that NF-κB directly induces MTDH by binding specific promoter regions in OC. We identified a feed-forward loop motif of MTDH and NF-κB in OC. However, it is worthy to verify this model in vivo, add histochemical demonstrations, consider to control the original level of the inflammation factors, and ensure the increased expression of these factors caused by MTDH overexpression.

Taken together, our results suggest MTDH as a rational target to explore for better understanding of OC biology and possibly provide an alternative OC treatment approach.
