ABSTRACT

A new test statistic is proposed to test the equality of two normal means when the data is partially paired and partially unpaired. The test statistic is based on a linear combination of the differences of both paired and unpaired sample means. Using t-distribution as the approximate null distribution, the proposed method is evaluated against some other standard methods known in the literature. For samples from normal and logistic distributions with equal variances, the proposed method appears to perform better than other methods with respect to power while keeping the type I error rates very competitive.

1. INTRODUCTION

This paper presents a new test statistic for comparing two means μ₁ and μ₂ under the following two types of data:

i. Type U Data: Data obtained from two independent random samples but, unknowingly or by accident, some units are used or found to be the same in both samples that resulted in some paired observations. The number of units common to both samples is expected to be small compared to unpaired sample sizes.

ii. Type P Data: Data obtained from paired design, but some data values are missing completely at random that resulted in some unpaired observations. Pairs with both missing observations are deleted. The numbers of first and second missing values (or equivalently the unpaired sample sizes) are expected to be small compared to unpaired sample sizes.

Type U data may be visualized as two random samples \((X_1, U_1) = (x_{11}, x_{12}, ..., x_{1n_1}, u_{11}, u_{12}, ..., u_{1n_2})\) and \((X_2, U_2) = (x_{21}, x_{22}, ..., x_{2n_1}, u_{21}, u_{22}, ..., u_{2n_2})\) of which \((U_1, U_2) = (u_{11}, u_{21}), (u_{12}, u_{22}), ..., (u_{1n_2}, u_{2n_2})\) are paired, and \(X_1 = (x_{11}, x_{12}, ..., x_{1n_1})\) and \(X_2 = (x_{21}, x_{22}, ..., x_{2n_1})\) are unpaired observations of the two independent samples.

Type P data is visualized as \(n_1 + n_2 + n\) pairs \((X_1, U_1)\), \((X_2, U_2)\) where \(n_1\) pairs \((X_1, U_1)\) have only second observations missing, \(n_2\) pairs \((X_2, U_2)\) have only first observations missing, and \(n\) complete pairs \((U_1, U_2)\) with no missing observations.

We assume that the paired data \((U_1, U_2)\) is a random sample from a bivariate normal distribution \(BN(\mu_1, \mu_2, \sigma_1^2, \sigma_2^2, \rho)\), and the unpaired data \(X_1\) and \(X_2\) are independent random samples from normal distributions \(N(\mu_1, \sigma_1^2)\) and \(N(\mu_2, \sigma_2^2)\), respectively. Notice that the means and variance parameters are same in bivariate normal and normal distributions.

Some studies that require testing \(H_0 : \mu_1 - \mu_2 = 0\) for Type U and Type P data described above are mentioned by several researchers (e.g., Uddin and Hasan [1], Samawi and Vogel [2], Rempala and Looney [3], Mehrotra [4], Looney and Jones [5], Hermann and Looney [6], Dimery et al. [7], Steere et al. [8], Nurnberger et al. [9], Bhoj [10], Ekbohm [11], Lin and Stivers [12]). A survey of various statistical methods proposed for use in this setting can be found in Guo and Yuan [13].

If the number (n) of paired data is too small compared to unpaired sample sizes \( n_1 \) and \( n_2 \), one may simply ignore the paired data and use two independent samples methods (e.g., independent samples t-test). Similarly, paired sample methods (e.g., paired t-test) can be used if the unpaired sample sizes \( n_1 \) and \( n_2 \) are too small compared to \( n \), the complete pairs. A third approach would be to ignore the pairing of data and run the two independent samples t-test. In each of the above three approaches, some information would be lost due to omitted observations or correlations between paired observations.

The present paper focuses only on tests of \( H_0 : \mu_1 - \mu_2 = 0 \) that use all available data on both samples as well as the correlation from paired observations. For the purpose of a brief literature review, first we use the following notations:

\[
\bar{x}_i = \text{sample mean of } n_i \text{ observations } x_{i1}, x_{i2}, \ldots, x_{in_i}, \ i = 1, 2.
\]

\[
s^2_i = \text{sample variance of } n_i \text{ observations } x_{i1}, x_{i2}, \ldots, x_{in_i}, \ i = 1, 2.
\]

\[
M_i = \text{sample mean of } n_i + n \text{ observations } x_{i1}, x_{i2}, \ldots, x_{in_i}, u_{1j}, u_{2j}, \ldots, u_{mn}, \ i = 1, 2.
\]

\[
s^2_i = \text{sample variance of } n_i + n \text{ observations } x_{i1}, x_{i2}, \ldots, x_{in_i}, u_{1j}, u_{2j}, \ldots, u_{mn}, \ i = 1, 2.
\]

\[\bar{d} = \text{sample mean of } n \text{ paired differences } u_{1j} - u_{2j}, j = 1, 2, \ldots, n.\]

\[
s^2_d = \text{sample variance of } n \text{ paired differences } u_{1j} - u_{2j}, j = 1, 2, \ldots, n.
\]

\[
s^2_{pd} = \text{sample variance of } n \text{ weighted paired differences } nu_{1j}/(n_1 + n) - nu_{2j}/(n_2 + n), j = 1, 2, \ldots, n.
\]

For Type U data under the assumption that \( \sigma^2_i = \sigma^2_j \), Bhoj [10] suggested the following test statistic \( T_c \):

\[
T_c = \lambda t_{f_c} + (1 - \lambda) t_{f_p} \quad \text{where} \quad t_{f_c} = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{(n_1-1)s^2_1 + (n_2-1)s^2_2}} / \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}, \quad t_{f_p} = \frac{\bar{d}}{\sqrt{\frac{1}{n} \cdot \frac{s^2_d}{n_1} + \frac{1}{n} \cdot \frac{s^2_d}{n_2}}}, \quad 0 \leq \lambda \leq 1.
\]

The above test statistic \( T_c \) is linear combination of the two independent samples t-statistic \( t_{f_p} \) for unpaired data with \( f_c = n_1 + n_2 - 2 \) degrees of freedom and paired t-test statistic \( t_{f_p} \) with \( f_p = n - 1 \) degrees of freedom. To accommodate for unequal variances, \( T_c \) is modified by Uddin and Hasan [1] to \( T_{cu} \):

\[
T_{cu} = \lambda' t_{f_c} + (1 - \lambda') t_{f_p}, \quad \text{where} \quad t_{f_c} = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{\frac{s^2_1}{n_1} + \frac{s^2_2}{n_2}}}.
\]

The sampling distribution of \( t_{f_c} \) is approximated by t-distribution with Satterthwaites [14] approximate degrees of freedom \( f_{cu} \), where

\[
f_{cu} = \left( \frac{\frac{s^2_1}{n_1} + \frac{s^2_2}{n_2}}{\frac{s^2_1}{n_1(n_1-1)} + \frac{s^2_2}{n_2(n_2-1)}} \right)^2.
\]

Looney and Jones [5] proposed the following alternative to \( T_c \):

\[
Z_{corr} = \frac{M_1 - M_2}{\sqrt{\frac{s^2_1}{n_1 + n} + \frac{s^2_2}{n_2 + n} - \frac{2nu_{1j}}{(n_1+n)(n_2+n)}}}.
\]

However, it is pointed out by Uddin and Hasan [1] that the test statistic \( Z_{corr} \) has a negative estimated variance problem and offered a solution to the problem. They suggest to modify \( Z_{corr} \) to \( Z_c \) as follows:

\[
Z_c = \frac{M_1 - M_2}{\sqrt{\frac{n_1s^2_1}{(n_1+n)^2} + \frac{n_2s^2_2}{(n_2+n)^2} + \frac{s^2_{pd}}{n}}}
\]

For the Type P data that results from a paired design with missing observations, Mehrotra [4] suggested that a test (here referred to as REML) of the above hypothesis can be carried out using SAS Proc Mixed.

The above test statistics are empirically compared with respect to type I error rates and powers for some selected values of sample sizes and correlations (see Uddin and Hasan [1], Mehrotra [4]). Under the assumption of equal variances, Mehrotra [4] used simulations to compare...
type I error rates and powers of REML, $Z_{\text{corr}}$ and $T_c$, and concluded that REML results in higher power than both $T_c$ and $Z_{\text{corr}}$ for large positive correlations.

In a recent paper, Uddin and Hasan [1] modified $Z_{\text{corr}}$ to $Z_2$ to correct for negative estimated variance problem, $T_c$ to $T_{cu}$ to account for unequal variances, and carried out a simulation study to compare REML, $Z_2$ and $T_{cu}$. For normally distributed data with equal variances, their simulation results provided empirical support to conclude that REML results in higher powers than $Z_2$ and $T_{cu}$ for large positive correlations. For all negative and small to moderate positive values of correlation, $Z_2$ appears to have higher powers than both REML and $T_{cu}$. For samples from normal distributions with unequal variances, $Z_2$ is outperformed jointly by $T_{cu}$ and REML, where REML is preferred to $T_{cu}$ for large positive correlations ($\rho$) and $T_{cu}$ for all other correlations. The choice of a test statistic thus depends on $\rho$ which will often be unknown in practice. Viewing this as a limitation of the above approaches, this paper is devoted to finding a single test statistic that would outperform others for all $\rho$ with respect to statistical powers while keeping the type I error rates very competitive.

In Section 2 below, we describe such a test statistic and offer approximate null sampling distribution of the proposed test statistic. Following an example in Section 3 from Rempala and Looney [3], we use simulation to show that the proposed test statistic performs very well in comparison to the alternative methods available in the literature for samples from normal and logistic distributions with equal variances.

2. PROPOSED TEST STATISTIC AND APPROXIMATE NULL SAMPLING DISTRIBUTION

As noted above both $T_c$ and $T_{cu}$ are defined as weighted average of unpaired and paired t-statistic. An alternative test statistic considered here is based on the weighted average $L(\omega) = \omega (\bar{x}_1 - \bar{x}_2) + (1 - \omega) (\bar{t}_1 - \bar{t}_2)$ of unpaired and paired mean differences with $\omega \in (0, 1)$ chosen so that $\text{var}(L(\omega)) = \omega^2 \sigma_x^2 (\bar{x}_1 - \bar{x}_2) + (1 - \omega)^2 \sigma_d^2$ is minimized. It follows that $\omega = \frac{\sigma_x^2}{\sigma_x^2 + \sigma_d^2}$ minimizes this variance where $\sigma_x^2$ is the variance of the sampling distribution of paired mean difference $\bar{d}$ and $\sigma_d^2$ is the variance of the sampling distribution of $(\bar{x}_1 - \bar{x}_2)$. If the null hypothesis $H_0$ is true and variances are known, then

$$\frac{\omega (\bar{x}_1 - \bar{x}_2) + (1 - \omega) \bar{d}}{\sqrt{\omega^2 \sigma_x^2 (\bar{x}_1 - \bar{x}_2) + (1 - \omega)^2 \sigma_d^2}}$$

is distributed as standard normal. In practice, the variances $\sigma_x^2$ and $\sigma_d^2$ and hence $\omega$ will be unknown and must be estimated from data. Since $\sigma_x^2$ is the variance of the sampling distribution of $(\bar{x}_1 - \bar{x}_2)$, a function of only unpaired observations, it is sensible to estimate this variance from unpaired data only. Similarly, $\sigma_d^2$ can be estimated using paired observations only. Analogous to paired and independent samples test of $H_0 : \mu_1 = \mu_2$, we suggest the following estimators:

$$\hat{\sigma}_x^2 = \frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}$$

$$\hat{\sigma}_d = \frac{1}{n} s_d^2$$

Replacing the unknown variances and hence $\omega$ by their estimates as shown above, and using a correction factor for the purpose of sampling distribution, we define the following test statistic:

$$T_u = \theta \frac{\hat{\omega} (\bar{x}_1 - \bar{x}_2) + (1 - \hat{\omega}) \hat{d}}{\sqrt{\hat{\omega}^2 \hat{\sigma}_x^2 (\bar{x}_1 - \bar{x}_2) + (1 - \hat{\omega})^2 \hat{\sigma}_d^2}}$$

$$\theta = \sqrt{\frac{2D - 3C^2}{CD}} \sqrt{\frac{\hat{\sigma}_x^2 + \hat{\sigma}_d^2}{\hat{\sigma}_x^2 + \hat{\sigma}_d^2}}$$

$$\omega = \frac{\hat{\sigma}_d^2}{\hat{\sigma}_x^2 + \hat{\sigma}_d^2}, \quad C = \frac{(n - 1) \hat{\sigma}_x^2 (\bar{x}_1 - \bar{x}_2)^2 + f_u \hat{\sigma}_d^2 (\bar{x}_1 - \bar{x}_2)^2}{(n - 3) (\hat{\sigma}_x^2 (\bar{x}_1 - \bar{x}_2)^2 + \hat{\sigma}_d^2 (\bar{x}_1 - \bar{x}_2)^2)},$$

$$D = \frac{3 (n - 1)^2 \hat{\sigma}_x^4 (\bar{x}_1 - \bar{x}_2)^4}{(n - 3) (n - 5) (\hat{\sigma}_x^2 (\bar{x}_1 - \bar{x}_2)^2 + \hat{\sigma}_d^2 (\bar{x}_1 - \bar{x}_2)^2)^2} + \frac{6 (n - 1) f_u \hat{\sigma}_d^2 (\bar{x}_1 - \bar{x}_2)^2 (\bar{x}_1 - \bar{x}_2)^2}{(n - 3) (n - 5) (\hat{\sigma}_x^2 (\bar{x}_1 - \bar{x}_2)^2 + \hat{\sigma}_d^2 (\bar{x}_1 - \bar{x}_2)^2)^2} + \frac{3 f_u^2 \hat{\sigma}_d^4 (\bar{x}_1 - \bar{x}_2)^4}{(f_u - 2) (f_u - 4) (\hat{\sigma}_x^2 (\bar{x}_1 - \bar{x}_2)^2 + \hat{\sigma}_d^2 (\bar{x}_1 - \bar{x}_2)^2)^2}.$$
It is noted here that the above $T_u$ without the correction factor $\vartheta$ reduces to $T_{ncw}$ of Samawi and Vogel [2] when $\vartheta = 1/2$ and the common variance $\sigma_2^2 = \sigma_2^2 = \sigma^2$ is estimated by the pooled variance of the unpaired samples. Here, we do not know the exact sampling distribution of $T_u$ under the null hypothesis. Following the procedure described in Uddin and Hasan [1], we approximate the null sampling distribution of $T_u$ by $t$-distribution with $(4D - 6C^2)/(D - 3C^2)$ degrees of freedom. This approximate null distribution is used in our simulation in Section 4 for the calculation of empirical type I error rates and powers of $T_u$ for some selected values of sample sizes and correlation values of paired observations. We have an illustrative example in Section 3 below.

3. A NUMERICAL EXAMPLE

In this example, we use the data from a clinical study on symptom management among hospice patients in the last days of life (see Hermann and Looney [6], Rempala and Looney [3]). The data values reported in Table 3 of Rempala and Looney [3] are Karnofsky Performance Status (KPS) scale scores. These values are obtained from 37 patients on the day before they died, from 32 patients on their last day of life, but nine patients were common on both days. The reader may review Hermann and Looney [6], Rempala and Looney [3] for more details on the last day and next-to-last day of life are significantly different. This conclusion is consistent with that reported by Uddin and Hasan [1].

To make it comparable to other simulation studies reported in the literature (e.g., Uddin and Hasan [1], Mehrotra [4]), we set our null and hypothesis. SAS IML (version 9.22) functions "randnormal(n, mean, cov)" are used for generating these samples. For each set of simulation parameters, type I error rates when $H_0 : \mu_1 - \mu_2 = 0$ and powers when $H_0 : \mu_1 - \mu_2 = 0.35$ were calculated for each of $Z_c$, REML and $T_u$ based on 10,000 samples mentioned above. Note that $T_{ncw}$ is not included here in our simulation with sampling from normal distributions with equal variances since $Z_c$ and REML are found by Uddin and Hasan [1] to jointly outperform $T_{ncw}$ for all correlation values. Our goal here is to compare the proposed test statistic $T_u$ to $Z_c$ and REML with respect to type I error rate and power. In the calculation of type I error rates and powers, we have used the null sampling distribution of $T_u$ from Section 2 above, but for $Z_c$, the null

4. SIMULATION: DISTRIBUTIONS AND PARAMETERS

To make it comparable to other simulation studies reported in the literature (e.g., Uddin and Hasan [1], Mehrotra [4]), we set our null and research hypothesis as $H_0 : \mu_1 - \mu_2 = 0$ and $H_1 : \mu_1 - \mu_2 = 0.35$ respectively. For some sample sizes and correlations, 10,000 random samples are generated from the corresponding normal and bivariate normal distributions with $\sigma_1^2 = \sigma_2^2 = 1$ under both null and research hypothesis. SAS IML (vector 9.22) functions "rand(normal, $\mu$, $\sigma$)" and "randnormal(n, mean, cov)" are used for generating these samples. For each set of simulation parameters, type I error rates when $H_0 : \mu_1 - \mu_2 = 0$ and powers when $H_0 : \mu_1 - \mu_2 = 0.35$ were calculated for each of $Z_c$, REML and $T_u$ based on 10,000 samples mentioned above. Note that $T_{ncw}$ is not included here in our simulation with sampling from normal distributions with equal variances since $Z_c$ and REML are found by Uddin and Hasan [1] to jointly outperform $T_{ncw}$ for all correlation values. Our goal here is to compare the proposed test statistic $T_u$ to $Z_c$ and REML with respect to type I error rate and power. In the calculation of type I error rates and powers, we have used the null sampling distribution of $T_u$ from Section 2 above, but for $Z_c$, the null

Uddin and M. S. Hasan. / Journal of Statistical Theory and Applications 19(2) 238–247
distribution described in Uddin and Hasan [1] is used. However, for REML, both type I error rate and power are determined by comparing significance probabilities obtained from the analysis carried out by SAS Proc Mixed with nominal \( \alpha = 0.05 \). The empirical type I error rates and powers obtained from our simulations are presented graphically in Figures 1 and 2 for some combinations of sample sizes and parameter values.

To study the robustness of the proposed test statistic, the above simulation is repeated for samples from logistic distribution, a non-normal symmetric distribution similar to normal but with heavier tails than the normal. The i-th logistic probability density function is given by

\[ f_i(x) = \frac{e^{-(x-\mu_i)/\sigma_i}}{\sigma_i(1 + e^{-(x-\mu_i)/\sigma_i})^2} \]

for which the mean and variance are \( \mu_i \) and \( \sigma_i^2 \pi^2 / 3 \). For notational convenience, we shall use \( \mu_i \) and \( \sigma_i^2 \) to refer to the mean and variance of the i-th logistic distribution, \( i = 1, 2 \). The null and research hypotheses are set as \( H_0 : \mu_1 = \mu_2 = 0, H_1 : \mu_1 - \mu_2 = 0.35 \), and standard deviations of the two distributions are set at \( (\sigma_1, \sigma_2) = (1, 1) \). Since the bivariate logistic distribution with the above marginal logistic distributions yield only \( \rho = 1/2 \), we randomly generated correlated pairs of cumulative probabilities, and then utilize the cumulative distribution function of the above logistic distribution to generate the paired sample data. This technique was previously used by Uddin and Hasan [1] in their simulation. Using samples from logistic distributions, Uddin and Hasan [1] provided empirical support in favor of using REML or \( Z_c \) depending on sample sizes and correlation values. Here the empirical type I error rates and powers of the proposed test statistic \( T_u \), displayed in Figures 3 and 4, are compared to that of REML and \( Z_c \) using samples from logistic distributions described above.

5. DISCUSSION AND CONCLUSION

For sampling from normal distributions with equal variances, the test statistic \( T_u \) shows higher power than REML for all \( \rho \), and higher powers than \( Z_c \) for moderate to large \( \rho \) considered here. However, due to the higher type I error rates of \( T_u \), particularly for negative \( \rho \) and type U data (see Figure 1) compared to that of \( Z_c \) and REML, one may argue that such power gains by \( T_u \) over \( Z_c \) and REML is the result of its inflated type I error rates. However, for type P data with positive \( \rho \) (see Figure 2), the competitive empirical type I error rates and power curves provide empirical support in favor of recommending \( T_u \) over \( Z_c \) and REML. Note that for type P data, we expect small unpaired sample sizes \( n_1, n_2 \) compared to paired sample size \( n \) whereas for type U data only a small number of complete pairs is expected compared to unpaired sample sizes. Note further that the correlation parameter \( \rho \) is expected to be positive in practice for paired data.

To investigate the robustness of \( T_u \) to non-normal distributions, we repeated our simulation using samples from logistic distributions described above. The test statistic \( Z_c \) was found by Uddin and Hasan [1] to be more liberal with respect to type I error rates in the sense that \( Z_c \) results in higher empirical type I error rates than the nominal \( \alpha \) value. They argued in favor of choosing \( T_u \) or REML depending on sample sizes and correlations for comparing means of logistic distributions. We thus excluded \( Z_c \) and compared the proposed \( T_u \) with \( T_{cu} \) and REML. The empirical type I error rates and powers of \( T_u, \) REML, and \( T_{cu} \) are displayed in Figures 3 and 4. A closer look at the plots in these two figures reveal that \( T_u \) results in higher type I error rate than the nominal \( \alpha \) whereas REML is more conservative with smaller type I error rate than the assumed nominal \( \alpha \) value for type U data. However, for type P data with positive correlations, the three test statistics appear to be very competitive with respect to type I error rates and \( T_u \) performs better with respect to power.

The present simulation study thus provided empirical support for choosing \( T_u \) for testing the equality of two means for type P data from normal distributions as well as from logistic distributions with equal variances when correlations of paired observations are positive. This is in contrast to findings in other simulations where, in the absence of \( T_u \), the choice of a test statistic depends on paired/unpaired sample sizes and correlations of paired data.

We have expanded our simulation to investigate the robustness of \( T_u \) for unequal variances for all sample sizes and correlations shown in Figures 1–4 for both normal and logistic distribution. We followed the same procedure described in Uddin and Hasan [1] for these expanded simulations. The proposed statistic \( T_u \) does not appear to perform well when compared to others when variances are unequal. We like to note that the empirical comparisons of these methods are limited in that the simulations are carried out only for some selected combinations of \( n_1, n_2, n, \sigma_1, \sigma_2 \), and \( \rho \) with \( H_1 : \mu_1 - \mu_2 = 0.35 \) using samples from normal and logistic distributions.

CONFLICT OF INTEREST

There is no conflict of interest.
