INTRODUCTION

Posttranslational modifications (PTMs) of core histones play important roles in regulating gene expression, DNA replication, DNA repair, and other DNA-templated biological processes. Whereas most PTMs involve covalent attachment of small chemical moieties (e.g., acetylation and methylation), monoubiquitylation comprises conjugation of the bulky 76-amino-acid ubiquitin protein to the ε-amino group of lysine. A well-studied example is monoubiquitylation of histone H2B on lysine 120 in yeast or lysine 120 in mammals (H2BK120ub1, abbreviated here as H2Bub1), carried out primarily by the yeast E3 ubiquitin ligase BRE1 (Hwang et al., 2003) and the orthologous heteromeric hBRE1(RNF20)/RNF40 mammalian complex (Kim et al., 2005; Zhu et al., 2005). Recent studies, relying mainly on manipulation of RNF20/RNF40, have provided insights into the compound roles of H2Bub1 in mammalian cells. Partial depletion of RNF20, which markedly reduces H2Bub1 levels, exerts opposite transcriptional effects on different gene subsets: H2Bub1 suppresses the transcription of other genes, including the p53 tumor suppressor (Shema et al., 2008). Such seemingly opposing functions of H2Bub1 in transcriptional regulation are supported by yeast studies (Chandrasekharan et al., 2009; Osley et al., 2006; Wyce et al., 2007). Additional work in mammalian cells revealed crucial roles for H2Bub1 in maintaining chromatin boundaries (Ma et al., 2011), promoting DNA damage repair (Kari et al., 2011; Moyal et al., 2011; Nakamura et al., 2011), histone messenger RNA 3' end processing (Pirmgruber et al., 2009), and stem cell differentiation (Fuchs et al., 2012; Kariuki et al., 2012). How H2Bub1 exerts its effects is largely unknown. H2Bub1 can impact directly the physical properties of chromatin, in particular its arrangement into higher-order structures (Fierz et al., 2011). H2Bub1 has also been implicated in enhancing nucleosome stability and mediating transcripational repression or activation, depending on the context and localization of the modification (Batta et al., 2011; Chandrasekharan et al., 2009). Other studies suggest that H2Bub1 may also serve as a signaling platform. Thus, yCps35/hWDR82 associates with chromatin in an H2Bub1-dependent manner, enhancing histone H3 lysine 4 methylation by COMPASS-type complexes (Lee et al., 2007; Wu et al., 2008). Furthermore, H2Bub1 stimulates H3 lysine 79 methylation by the DOT1 histone methyltransferase (Lee et al., 2007; McGinty et al., 2008). H2Bub1 can also affect nonhistone...
Figure 1. Identification and Validation of H2Bub1-Interacting Proteins

(A) Experimental workflow of the chromatin affinity purification.

(B) Scatterplot representing normalized enrichment ratios of proteins from two label swap chromatin affinity purification experiments. Proteins with log2-transformed ratios above 1.0 in each experiment and above 1.5 average are in dark gray. Upper right quadrant and lower left quadrant display proteins enriched with H2Bub1 chromatin or unmodified chromatin, respectively; protein identities are listed in Table S1. Factors belonging to five indicated complexes are color-coded. Histones and ubiquitin, identified only in light form as part of the affinity matrix, are displayed in the upper left quadrant.

(C) Significantly enriched biological functions (Ingenuity Pathway Analysis, B-H corrected p value < 0.05) associated with proteins selectively bound to H2Bub1-rich chromatin. See Table S2 for a detailed list of the biological functions, canonical pathways, and individual proteins with associated p values.

(legend continued on next page)
proteins, as demonstrated by its requirement for methylation of Dam1 at the kinetochore (Latham et al., 2011). We now report the systematic identification of proteins that bind favorably to H2Bub1-rich chromatin and show that preferential binding of the SWI/SNF chromatin remodeling complex to specific genes via H2Bub1 is required for optimal transcription of those genes.

RESULTS

Systematic Identification of H2Bub1-Binding Proteins

To obtain insights into the diverse functions of H2Bub1, we utilized an approach we (Nikolov et al., 2011) and others (Bartke et al., 2010) previously applied for identification of specific histone PTM-binding proteins in the context of chromatin. Semisynthetic H2Bub1 (Haj-Yahya et al., 2012) (see also Figure S1A) was used in reconstitution of recombinant chromatin on a biotinylated DNA template (“H2Bub1-rich chromatin”). The resulting nucleosomal array, as well as one with nonmodified H2B, served as affinity matrices for enrichment of factors from SILAC-labeled (Ong and Mann, 2007) nuclear extracts (Figure 1A). We compared the proteins recruited to unmodified chromatin versus H2Bub1-rich chromatin using quantitative mass spectrometry. To minimize false-positive hits, two independent SILAC label-swap experiments were performed (Figures 1B and S1B). The list of factors preferentially associated with H2Bub1-rich chromatin (average log2 enrichment ratio > 1.5) contains more than 90 proteins, greatly expanding the known H2Bub1 interactome (Table S1). Of these, WDR82 is known to associate with chromatin in a H2Bub1-dependent manner (Wu et al., 2008), whereas chromodomains of H2Bub1-rich DNA binding protein 1 (CHD1) is crucial for maintaining high H2Bub1 levels (Lee et al., 2012).

Remarkably, the enriched set includes multiple components of several protein complexes (examples are color coded in Figure 1B), deduced from interaction relationships based on experimental or curated database evidence (Figure S1C). Ingenuity Pathway Analysis (Ingenuity Systems, http://ingenuity.com) revealed a number of highly enriched (B-H corrected p value < 0.05) biological functions, including RNA posttranscriptional modification, gene expression, and DNA replication, recombination, and repair (Figure 1C; Table S2). Notably, control affinity purification using biotinylated recombinant ubiquitin as bait failed to yield similar binding partners (Figure S1D).

We repeated the affinity purification and analyzed the enriched material by western blotting (Figure 1D), verifying specific enrichment on H2Bub1-rich chromatin of NELFA, a subunit of the NELF negative elongation complex; SUPT5H, a subunit of the DSIF complex; BAF155, a subunit of the SWI/SNF complex; and INT3S3, a subunit of the Integrator (INT) complex (Baillat et al., 2005). Remarkably, all other known subunits of the NELF and DSIF complexes and several other subunits of the INT and SWI/SNF complexes were also identified as preferential binders to H2Bub1-rich chromatin (Figure 1B; Table S1). Likewise, we validated modification-dependent enrichment of the DNA helicase RECQL5, a putative tumor suppressor implicated in maintaining genome stability (Islam et al., 2010); the DYRK1A kinase, implicated in neuronal development and neurodegenerative diseases (Wegiel et al., 2011); and the MORC2 CW zinc finger protein, involved in histone deacetylation (Shao et al., 2010) (Figure 1D). Conversely, a small group of proteins, including Regulator of Chromosome Condensation 1 (RCC1), bound preferentially the nonmodified template (Figure 1B, lower left quadrant; Figure 1D). In contrast, HDAC1 was not found enriched on either template by mass spectrometry (MS) or western blot. Importantly, analysis of histones H2A, H3, and H4 confirmed equal amounts of chromatin template in all experiments.

H2Bub1-Dependent Differential Interactions within Cells

The two subunits of the DSIF complex, SUPT4H and SUPT5H, were among the most highly enriched binders of H2Bub1-rich chromatin (Figure 1B). Notably, a functional link between H2Bub1 and Spt5, the ortholog of SUPT5H, has recently been described in fission yeast (Sansó et al., 2012).

To examine this interaction in vivo, we transiently expressed in HeLa cells either FLAG-tagged wild-type (WT) H2B or H2B mutated at lysines 120 and 125 (H2B2KR), rendering it ubiquitylation resistant (Minsky and Oren, 2004). Cell extracts were subjected to coimmunoprecipitation (coIP) with antibodies against FLAG followed by western blot analysis with antibodies against SUPT5H. As seen in Figure 2A, more SUPT5H associated with WT than with mutant H2B, confirming that this interaction is favored by H2Bub1.

We then asked whether transient reduction of H2Bub1 levels, via small interfering RNA (siRNA)-mediated RNF20 depletion, decreases the association of SUPT5H with chromatin. However, despite reduced H2Bub1 levels, significant changes in the association of SUPT5H could not be detected (Figure S2). Conceivably, the affinity of SUPT5H to H2Bub1 might be so strong that a 2- to 3-fold decrease in H2Bub1 may not suffice to reduce substantially its recruitment to chromatin. In such cases, lower-affinity interactions are expected to be more sensitive to a modest decrease in H2Bub1. Indeed WDR82, a moderate preferential binder in our MS screen, was shown to associate with chromatin in an H2Bub1-dependent manner (Wu et al., 2008).

SWI/SNF Associates Preferentially with H2Bub1-Rich Chromatin

The group of moderate preferential binders to H2Bub1-rich chromatin comprised several subunits of the SWI/SNF chromatin remodeling complex (BRG1, BRM, BAF155, and BAF170; Figures 1B and S1C), suggesting that H2B ubiquitylation may help recruit this complex to chromatin. Mammalian SWI/SNF complexes contain multiple subunits: one of the two mutually exclusive catalytic ATPase subunits BRM and BRG1; several highly

(D) Affinity purification of HeLa extracts on chromatin templates, reconstituted with either unmodified H2B or H2Bub1, was performed as in (A), except that extracts were not stable-isotope labeled and bound proteins were analyzed by western blot with the indicated antibodies. Left: proteins binding preferentially to the H2Bub1-rich chromatin template according to MS. Right: HDAC1 (identified in background by MS), RCC1 (found preferentially on the unmodified template by MS), and histone proteins from chromatin templates. See also Figure S1.
conserved core subunits including INI1 (SNF5/SMARCB1), BAF155 (SMARCC1), and BAF170; and various associated polypeptides. SWI/SNF complexes mobilize nucleosomes, as well as evict H2A/H2B dimers and entire histone octamers, and thereby can either enhance or suppress transcription (Wilson and Roberts, 2011; Wu et al., 2009).

SWI/SNF complex components were specifically recruited to chromatin containing H2BK120ub1 but not H2BK34ub1, another histone ubiquitylation recently identified (Siman et al., 2013; Wu et al., 2011) (Figure 2B). To validate the preferential interaction of SWI/SNF with H2Bub1-rich chromatin in vivo, we performed colp experiments with FLAG-tagged WT H2B or H2B2KR after transient overexpression in HeLa cells. As seen in Figure 2C, endogenous BAF155 was preferentially recruited by WT H2B as compared to the H2B2KR mutant (IP-FLAG; compare lanes 2 and 3). Furthermore, RNF20 depletion reduced markedly the association of H2B with BAF155 (Figures 2D and S2C, siRNF20).

**SWI/SNF Is Required for Optimal Transcription of RNF20-Dependent Genes**

Preferential recruitment of SWI/SNF to H2Bub1-rich chromatin might facilitate the transcription of RNF20-dependent genes, thereby explaining their dependence. We therefore monitored the expression of representative genes upon knockdown of several SWI/SNF subunits (Figure 3A). Depletion of RNF20, but not BRG1, BAF155, or BRM, downregulated global H2Bub1 levels (Figure 3B). As reported (Shema et al., 2008), expression of the RNF20-dependent genes p53, H2BD, HOX1A, GDF15, AP1TD1, TSN, and CD46 decreased significantly (Figure 3C, siRNF20). Importantly, a comparable decrease was observed also upon knockdown of BRG1 and, to a lesser extent, BAF155. In contrast, BRM depletion had little effect. Depletion of BRG1, BRM, or BAF155 did not affect the RNF20-independent genes GAPDH and NDUFA6 or the RNF20-suppressed genes MYC and FOS (Figure 3D). Thus, SWI/SNF is selectively involved in the positive regulation of genes whose transcription is dependent on RNF20 and H2Bub1.

**H2Bub1 Modulates Gene Expression by Affecting SWI/SNF Recruitment**

To test whether H2Bub1 is involved in recruiting SWI/SNF to specific loci, we performed chromatin immunoprecipitation (ChiP) analysis to examine the association of BRG1 with the transcription start site (TSS) or the 5' regions of representative genes. As seen in Figure 4A, RNF20 knockdown reduced the association of BRG1 with genes positively regulated by RNF20 and H2Bub1, but not with the RNF20-suppressed FOS and the RNF20-independent GAPDH, p21, and NDUFA6 genes, although H2Bub1 levels were reduced at all tested sites (Figure 4B). Notably, RNA polymerase II (Pol II) occupancy on the TSS and 5' regions of p53 and H2BD did not decrease (Figure S3A), indicating that the reduction in BRG1 is specific and not merely correlated to Pol II levels in these regions. This suggests that BRG1, and presumably the SWI/SNF complex as a whole, is recruited in an H2Bub1-dependent manner to a specific subset of genes, selectively facilitating their transcription.

We next asked whether BRG1 overexpression (Figures S3B and S3C) could rescue the transcription of RNF20-dependent genes in RNF20-depleted cells. RNF20 knockdown reduced the expression of all RNF20-dependent genes tested (Figure 4C, first and third bars). Notably, BRG1 overexpression partially rescued this defect (fourth and third bars), while not affecting siLacZ control cells (second and first bars). This suggests that H2Bub1 is selectively required to recruit to those...
We show that H2Bub1-reconstituted chromatin selectively associates with particular proteins, indicating that this PTM serves as recruiting signal within chromatin. Like antibodies against H2Bub1 (Minsky et al., 2008), some factors may recognize directly a unique structure at the H2B-ubiquitin junction. Alternatively, recognition may encompass cooperativity where ubiquitin together with other chromatin components (histones and DNA) need to be bound simultaneously. Since H2Bub1 alters higher-order chromatin folding (Fierz et al., 2011), some of the preferentially interacting complexes may recognize different chromatin conformational states in an indirect binding mode rather than interact directly with H2Bub1. So far, we have been unable to demonstrate a direct interaction between H2Bub1-rich chromatin and recombinant SWI/SNF subunits. We attempted to purify SWI/SNF complex via INI1-FLAG immunoprecipitation; however, only weak preferential binding to H2Bub1-rich chromatin was observed (data not shown). Hence, the selective interaction observed in nuclear extracts may rely on a composite signal (i.e., containing multiple direct and indirect components). This notion is supported by the differential interaction of SWI/SNF with chromatin containing H2BK120ub1 or H2BK34ub1. The exact nature and mechanism of SWI/SNF binding to H2BK120ub1-rich chromatin requires further investigation.

Besides locally opening chromatin structure to increase accessibility to repair proteins (Moyal et al., 2011; Nakamura et al., 2011), H2Bub1 may play a more direct role in double-strand break (DSB) repair. We found that several proteins recruited to DSBs to mediate DNA repair are enriched on H2Bub1, including subunits of the BRCA1-A complex (NBA1, RAP80, BRE, CCDC98, and BRCC3), the E3 ubiquitin ligase RNF168, and the DNA helicase RECQL5 (Doil et al., 2009; Popuri et al., 2012). Likewise, enrichment for ERCC1 and ERCC4 (XPF) suggests a role for H2Bub1 in nucleotide excision repair (Fagbemi et al., 2011).

H2Bub1 exerts opposing transcriptional effects on different classes of genes (Chandrasekharan et al., 2009; Osley et al., 2006; Wyce et al., 2007). In mammalian cells, loci suppressed by the differential interaction of SWI/SNF with chromatin containing H2BK120ub1 or H2BK34ub1. The exact nature and mechanism of SWI/SNF binding to H2BK120ub1-rich chromatin requires further investigation.

**DISCUSSION**

We show that H2Bub1-reconstituted chromatin selectively associates with particular proteins, indicating that this PTM serves as recruiting signal within chromatin. Like antibodies against H2Bub1 (Minsky et al., 2008), some factors may recognize directly a unique structure at the H2B-ubiquitin junction. Alternatively, recognition may encompass cooperativity where ubiquitin together with other chromatin components (histones and DNA) need to be bound simultaneously. Since H2Bub1 alters higher-order chromatin folding (Fierz et al., 2011), some of the preferentially interacting complexes may recognize different chromatin conformational states in an indirect binding mode rather than interact directly with H2Bub1. So far, we have been unable to demonstrate a direct interaction between H2Bub1-rich chromatin and recombinant SWI/SNF subunits. We attempted to purify SWI/SNF complex via INI1-FLAG immunoprecipitation; however, only weak preferential binding to H2Bub1-rich chromatin was observed (data not shown). Hence, the selective interaction observed in nuclear extracts may rely on a composite signal (i.e., containing multiple direct and indirect components). This notion is supported by the differential interaction of SWI/SNF with chromatin containing H2BK120ub1 or H2BK34ub1. The exact nature and mechanism of SWI/SNF binding to H2BK120ub1-rich chromatin requires further investigation.

Besides locally opening chromatin structure to increase accessibility to repair proteins (Moyal et al., 2011; Nakamura et al., 2011), H2Bub1 may play a more direct role in double-strand break (DSB) repair. We found that several proteins recruited to DSBs to mediate DNA repair are enriched on H2Bub1, including subunits of the BRCA1-A complex (NBA1, RAP80, BRE, CCDC98, and BRCC3), the E3 ubiquitin ligase RNF168, and the DNA helicase RECQL5 (Doil et al., 2009; Popuri et al., 2012). Likewise, enrichment for ERCC1 and ERCC4 (XPF) suggests a role for H2Bub1 in nucleotide excision repair (Fagbemi et al., 2011).

H2Bub1 exerts opposing transcriptional effects on different classes of genes (Chandrasekharan et al., 2009; Osley et al., 2006; Wyce et al., 2007). In mammalian cells, loci suppressed by the differential interaction of SWI/SNF with chromatin containing H2BK120ub1 or H2BK34ub1. The exact nature and mechanism of SWI/SNF binding to H2BK120ub1-rich chromatin requires further investigation.

**Figure 3. SWI/SNF Is Selectively Required for Optimal Transcription of RNF20-Dependent Genes**

(A) HeLa cells were transiently transfected with siRNA oligonucleotides targeting LacZ (control), RNF20, or each of the following subunits of the SWI/SNF complex: BRG1, BAF155, and BRM. Cells were harvested 48 hr later and RNA was extracted and analyzed by quantitative RT-PCR, employing primers specific for the indicated genes. For each gene, messenger RNA (mRNA) levels were first normalized to GAPDH mRNA in the same sample and then divided by the normalized levels of the same transcript in the control siLacZ sample, set as 1. Error bars represent the SD of duplicate qPCR reactions. Similar data were obtained in three independent experiments.

(B) HeLa cells were transfected as in (A), and cells were harvested 48 hr later and subjected to western blot analysis. GAPDH served as loading control.

(C) HeLa cells were transfected and analyzed as in (A), employing primers specific for RNF20-dependent genes.

(D) HeLa cells were transfected and analyzed as in (A), employing primers specific for the RNF20-independent GAPDH and NDUFA6 and the RNF20-suppressed MYC and FOS genes. GAPDH mRNA levels in each sample, relative to the siLacZ culture, are also shown.
by high RNF20/H2Bub1 reside within relatively closed chromatin and are excessively loaded with stalled or paused Pol II (Shema et al., 2008). Their expression depends on the transcription elongation factor TFIIIS, which is required for overcoming Pol II pausing and whose recruitment to chromatin is inhibited by H2Bub1 (Shema et al., 2011). We found that H2Bub1-rich chromatin favors the binding of two negative elongation complexes, DSIF and NELF, as well as several subunits of Pol II (Figure 1B). The ability of NELF to inhibit binding of TFIIIS to Pol II (Palangat et al., 2005) might explain the inhibitory effect of H2Bub1 on RNF20/H2Bub1-suppressed genes.

While mammalian H2Bub1 is mostly implicated in transcriptional elongation (Minsky et al., 2008), SWI/SNF regulates both initiation and elongation (Batsché et al., 2006; Corey et al., 2003; Euskirchen et al., 2011; Schwabish and Struhl, 2007). SWI/SNF is mostly associated with the promoter, TSS, and 5' region (Euskirchen et al., 2011), but is also present throughout the coding regions of some genes (Corey et al., 2003; Schwabish and Struhl, 2007). Different histone PTMs have been implicated in locally recruiting/retaining and modulating the activity of chromatin remodeling complexes. Thus, acetylated histones promote retention of SWI/SNF on gene promoters (Hassan et al., 2001). Likewise, histone H3 methylation on lysine 4, favored by H2Bub1 (Lee et al., 2007), mediates the association of SNF2H (subunit of the Isw1 remodeling complex) with chromatin in vivo (Nakamura et al., 2011; Santos-Rosa et al., 2003). Recently, H3K56ac was shown to regulate the histone exchange activity of SWR-C (Watanabe et al., 2013). We found that genes sensitive to RNF20 depletion are generally more dependent on BRG1 and presumably SWI/SNF for efficient transcription. Why this particular set of genes is so dependent on SWI/SNF remains an open question. Perhaps optimal expression of such genes is negatively regulated by particularly stable nucleosome(s), which need to be remodeled in an ATP-dependent manner in order to allow efficient transcription. Alternatively, other transcription-related functions distinct from nucleosome remodeling may be involved.

H2Bub1 deregulation has been extensively linked to cancer (reviewed in Johnsen, 2012). We expand this link, as many preferential H2Bub1 interactors harbor tumor-suppressive properties. Notably, mutations in genes encoding SWI/SNF subunits were found in tumors (Hargreaves and Crabtree, 2011; Wilson and Roberts, 2011). By recruiting protein complexes involved in DNA repair and transcriptional control, H2Bub1 may help to maintain cellular homeostasis and genome stability. Deregression of H2Bub1 may compromise these processes, eventually promoting cancer.
EXPERIMENTAL PROCEDURES

Chromatin Affinity Purification
Chromatin affinity purification, MS, and data analysis were carried out as described using an immobilized H2Bub1 containing 12-mer oligonucleosomal array (Nikolov et al., 2011). Synthesis and characterization of H2BK34ub1 is described in Siman et al. (2013).

RNA Purification and Quantitative Real-Time PCR
Total RNA was extracted with the NucleoSpin kit (Macherey Nagel). A total of 2–5 μg of each RNA sample was reverse transcribed with Moloney murine leukemia virus reverse transcriptase (Promega) and random hexamer primers (Applied Biosystems). Real-time PCR was performed in a StepOne real-time PCR instrument (Applied Biosystems) with SYBR Green PCR Supermix (Invitrogen). The primers used are listed in Table S3.

Chromatin Immunoprecipitation
ChIP analysis was performed as described elsewhere (Nelson et al., 2006). The primers used are listed in Table S3.

For further details, please refer to Extended Experimental Procedures.

SUPPLEMENTAL INFORMATION

Supplemental Information includes Extended Experimental Procedures, three figures, and three tables and can be found with this article online at http://dx.doi.org/10.1016/j.celrep.2013.07.014.
