Abstract
In the framework of the theory of open systems based on completely positive quantum dynamical semigroups, we present a description of continuous-variable entanglement for a system consisting of two non-interacting modes embedded in a thermal environment. By using the Peres–Simon necessary and sufficient criterion for the separability of two-mode Gaussian states, we describe the evolution of entanglement in terms of the covariance matrix for Gaussian input states. For all values of the temperature of the thermal reservoir, an initial separable Gaussian state remains separable for all times. In the case of an entangled initial Gaussian state, entanglement suppression (entanglement sudden death) takes place for non-zero temperatures of the environment. Only for zero temperature of the thermal bath, the initial entangled state remains entangled for finite times. We also show that, independent of its type, namely separable or entangled, the initial state evolves asymptotically to an equilibrium state that is always separable.

1. Introduction
In recent years there has been increasing interest in the use of continuous variable (CV) systems in applications of quantum information processing, communication and computation [1]. The realization of quantum information processing tasks depends on the generation and manipulation of non-classical entangled states of CV systems. A full characterization of the non-classical properties of entangled states of CV systems is available, at present, only for the class of Gaussian states. In this special case, there exist necessary and sufficient criteria of entanglement [2, 3] and quantitative entanglement measures [4, 5]. In the quantum information theory of CV systems, Gaussian states, in particular two-mode Gaussian states, play a key role, since they can be easily created and controlled experimentally.

In the implementation of quantum communication and computation, one encounters the difficulty that a realistic quantum system cannot be isolated and it always has to interact with its environment. Quantum coherence and entanglement of quantum systems are inevitably influenced during their interaction with the external environment. As a result of the irreversible and uncontrollable phenomenon of quantum decoherence, the purity and entanglement of quantum states are in most cases degraded. Practically, compared with the discrete variable entangled states, the CV entangled states may be more efficient because they are less affected by decoherence.

Due to the unavoidable interaction with the environment, any pure quantum state evolves into a mixed state, and to describe realistically CV quantum information processes, it is necessary to take decoherence and dissipation into consideration. The decoherence and dynamics of quantum entanglement in CV open systems have been intensively studied in recent years [6–21]. If two systems are immersed in an environment, then, in addition to and at the same time as the quantum decoherence phenomenon, the environment can also generate a quantum entanglement of the two systems and therefore an additional mechanism to correlate them [14, 22–25].

In this paper, we study, in the framework of the theory of open systems based on completely positive quantum dynamical semigroups, the dynamics of the CV entanglement of two uncoupled modes (two uncoupled...
harmonic oscillators) interacting with a common thermal environment. The initial state of the subsystem is assumed to be of Gaussian form and the evolution under the quantum dynamical semigroup ensures the preservation in time of the Gaussian form of the state. We have studied previously \cite{26, 27} the evolution of the entanglement of two identical harmonic oscillators interacting with a general environment, characterized by general diffusion and dissipation coefficients. We found that, depending on the values of these coefficients, the state keeps for all times its initial type: separable or entangled. In other cases, entanglement generation, entanglement sudden death or a periodic collapse and revival of entanglement take place.

The paper is organized as follows. In section 2 we write the Markovian master equation in the Heisenberg representation for two uncoupled harmonic oscillators interacting with a general environment and the evolution equation for the covariance matrix. For this equation we give its general solution, i.e. we derive the variances and equation for the covariance matrix. For this equation we introduce such quantum dynamical semigroups that preserve this set during time evolution of the system and the evolution under the quantum dynamical semigroup ensures the preservation in infinite time it evolves asymptotically to an equilibrium state that is always separable. We also analyze the time evolution of the logarithmic negativity, which characterizes the degree of entanglement of the quantum state. A summary is given in section 4.

2. Equations of motion for two harmonic oscillators

We study the dynamics of the subsystem composed of two non-interacting oscillators in weak interaction with a thermal environment. In the axiomatic formalism based on completely positive quantum dynamical semigroups, the irreversible time evolution of an open system is described by the following general quantum Markovian master equation for an operator $A$ in the Heisenberg representation († denotes Hermitian conjugation) \cite{29, 30}:

$$\frac{dA}{dt} = i\hbar[H, A] + \frac{1}{2\hbar} \sum_j (V_j A, V_j) + [V_j, A][V_j].$$

Here, $H$ denotes the Hamiltonian of the open system and the operators $V_j, V_j^\dagger$ defined on the Hilbert space of $H$, represent the interaction of the open system with the environment.

We are interested in the set of Gaussian states; therefore we introduce such quantum dynamical semigroups that preserve this set during time evolution of the system and in this case our model represents a Gaussian noise channel. Consequently, $H$ is taken to be a polynomial of second degree in the coordinates $x$, $y$ and momenta $p_x$, $p_y$ of the two quantum oscillators and $V_j, V_j^\dagger$ are taken as polynomials of first degree in these canonical observables. Then in the linear space spanned by the coordinates and momenta, there exist only four linearly independent operators $V_j=1,2,3,4$ \cite{31},

$$V_j = a_{ij} p_x + a_{jy} p_y + b_{ij} x + b_{jy} y,$$

where $a_{ij}, a_{jy}, b_{ij}$ and $b_{jy}$ are complex coefficients. The Hamiltonian of the two uncoupled non-resonant harmonic oscillators of identical mass $m$ and frequencies $\omega_1$ and $\omega_2$ is

$$H = \frac{1}{2m}(p_x^2 + p_y^2) + \frac{m}{2}(\omega_1^2 x^2 + \omega_2^2 y^2).$$

The fact that the evolution is given by a dynamical semigroup implies the positivity of the matrix formed by the scalar products of the four vectors $a_1, b_1, a_2, b_2$, whose entries are the components $a_{ij}, b_{ij}$, respectively. We assume this matrix to be of the following form, where all coefficients $D_{xx}, D_{xp}, \ldots$ and $\lambda$ are real quantities (we put, for now on, $\hbar = 1$):

$$\left( \begin{array}{cccc}
D_{xx} & -D_{xp} - i\frac{\lambda}{2} & D_{xy} & -D_{yp} \\
-D_{xp} + i\frac{\lambda}{2} & D_{xx} & -D_{yp} & D_{yp} \\
D_{xy} & -D_{yp} & D_{xx} & -D_{yp} - i\frac{\lambda}{2} \\
-D_{yp} & D_{yp} & -D_{yp} & D_{xx} \end{array} \right).$$

It follows that the principal minors of this matrix are positive or zero. From the Cauchy–Schwarz inequality, the following relations hold for the coefficients defined in equation (4):

$$D_{xx} D_{pp} - D_{xp}^2 \geq \frac{\lambda^2}{4}, \quad D_{xx} D_{pp} - D_{xp}^2 \geq \frac{\lambda^2}{4},$$

$$D_{xx} D_{yy} - D_{xy}^2 \geq 0, \quad D_{xx} D_{pp} - D_{xp}^2 \geq 0,$$

$$D_{xx} D_{pp} - D_{xp}^2 \geq 0, \quad D_{yy} D_{pp} - D_{yp}^2 \geq 0.$$

We introduce the following $4 \times 4$ bimodal covariance matrix:

$$\sigma(t) = \left( \begin{array}{cccc}
\sigma_{xx}(t) & \sigma_{xp}(t) & \sigma_{xy}(t) & \sigma_{yp}(t) \\
\sigma_{xp}(t) & \sigma_{xx}(t) & \sigma_{yp}(t) & \sigma_{yp}(t) \\
\sigma_{xy}(t) & \sigma_{yp}(t) & \sigma_{yy}(t) & \sigma_{yp}(t) \\
\sigma_{yp}(t) & \sigma_{yp}(t) & \sigma_{yp}(t) & \sigma_{pp}(t) \end{array} \right).$$

We can transform the problem of solving the master equation for the operators in Heisenberg representation into the problem of solving first order in time, coupled linear differential equations for the covariance matrix elements. Namely, from equation (1), we obtain the following system of equations for the quantum correlations of the canonical observables ($T$ denotes the transposed matrix) \cite{31}:

$$\frac{d\sigma(t)}{dt} = Y \sigma(t) + \sigma(t) Y^T + 2D,$$

where

$$Y = \left( \begin{array}{cccc}
-\lambda & 1/m & 0 & 0 \\
-m\omega_1^2 & -\lambda & 0 & 0 \\
0 & 0 & -\lambda & 1/m \\
0 & 0 & -m\omega_2^2 & -\lambda \end{array} \right).$$
The time-dependent solution of equation (7) is given as [31]

$$\sigma(t) = M(t)[\sigma(0) - \sigma(\infty)]M^T(t) + \sigma(\infty),$$

where the matrix $M(t) = \exp(Yt)$ has to fulfil the condition $\lim_{t \to \infty} M(t) = 0$. In order that this limit exists, $Y$ must only have eigenvalues with negative real parts. The values at infinity are obtained from the equation

$$Y\sigma(\infty) + \sigma(\infty)Y^T = -2D.$$  

(11)

3. Dynamics of two-mode CV entanglement

A well-known sufficient condition for in separability is the so-called Peres–Horodecki criterion [28, 32], which is based on the observation that the non-completely positive nature of the partial transposition operation of the density matrix for a bipartite system (transposition with respect to degrees of freedom of one subsystem only) may turn an inseparable state into a non-physical state. A signature of this non-physicality, and thus of quantum entanglement, is the appearance of a negative eigenvalue in the eigenspectrum of the partially transposed density matrix of a bipartite system.

A characterization of the separability of CV states using second-order moments of quadrature operators was presented for Gaussian states, whose statistical properties are fully characterized by just second-order moments, this

$$S$$

in $S$-separable Gaussian CV states: the necessary and sufficient criterion for invariants, Simon [4].

$A$ do not affect the entanglement) contains four local symplectic transformations that have been set to zero by means of local unitary operations that

$\det C$ non-zero values, the states with $\det C \neq 0$ may be possible that the states are entangled.

The two-mode Gaussian state is entirely specified by its covariance matrix (6), which is a real, symmetric and positive matrix with the following block structure:

$$\sigma(t) = \begin{pmatrix} A & C \\ C^T & B \end{pmatrix},$$

(12)

where $A$, $B$ and $C$ are $2 \times 2$ Hermitian matrices. $A$ and $B$ denote the symmetric covariance matrices for the individual reduced one-mode states, while the matrix $C$ contains the cross-correlations between modes. When these correlations have non-zero values, the states with $\det C \geq 0$ are separable but for $\det C < 0$ it may be possible that the states are entangled.

The $4 \times 4$ covariance matrix (12) (where all first moments have been set to zero by means of local unitary operations that do not affect the entanglement) contains four local symplectic invariants in the form of the determinants of the block matrices $A$, $B$, $C$ and covariance matrix $\sigma$. Based on the above invariants, Simon [2] derived a PPT criterion for bipartite Gaussian CV states: the necessary and sufficient criterion for separability is $S(t) \geq 0$, where

$$S(t) = \det A \det B + \left(1 - \det C\right)^2 - \text{Tr}[ACJCBJC^TJ] - \frac{1}{4}(\det A + \det B) \quad \text{(13)}$$

and $J$ is the $2 \times 2$ symplectic matrix

$$J = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}. \quad \text{(14)}$$

3.1. Time evolution of entanglement and logarithmic negativity

We suppose that the asymptotic state of the considered open system is a Gibbs state corresponding to two independent quantum harmonic oscillators in thermal equilibrium at temperature $T$. Then the quantum diffusion coefficients have the following form [30]:

$$m_{\omega_1}D_{xx} = \frac{D_{p,p_x}}{m_{\omega_1}} = \frac{\lambda}{2}\coth\frac{\omega_1}{2kT},$$

$$m_{\omega_2}D_{yy} = \frac{D_{p,p_y}}{m_{\omega_2}} = \frac{\lambda}{2}\coth\frac{\omega_2}{2kT},$$

$$D_{xp} = D_{yp} = D_{xy} = D_{p_xp_y} = 0.$$  

(15)

The elements of the covariance matrix depend on $Y$ and $D$ and can be calculated from equations (10) and (11). Solving for the time evolution of the covariance matrix elements, we can obtain the entanglement dynamics through the computation of the Simon criterion.

For Gaussian states, the measures of entanglement of bipartite systems are based on some invariants constructed from the elements of the covariance matrix [7, 11, 33]. To quantify the degrees of entanglement of the infinite-dimensional bipartite system states of the two oscillators, it is suitable to use the logarithmic negativity. For a Gaussian density operator, the logarithmic negativity is completely defined by the symplectic spectrum of the partial transpose of the covariance matrix. It is given by $E_N = -\log_2 \tilde{\nu}_-\nu_-,\quad \text{where} \quad \tilde{\nu}_- = \min\{\nu_-,\nu_+\}$.

The two-mode Gaussian state is separable if and only if the partial transpose of its density matrix is non-negative (positive partial transpose (PPT) criterion).

In our model, the logarithmic negativity is calculated as

$$E_N(t) = -\frac{1}{2} \log_2[4 f(\sigma(t))],$$

(17)

where

$$f(\sigma(t)) = \frac{1}{2}(\det A + \det B) - \det C - \left(\frac{1}{2}(\det A + \det B) - \det C\right)^2 - (\det \sigma(t))^{1/2}. \quad \text{(18)}$$

It determines the strength of entanglement for $E_N(t) > 0$, and if $E_N(t) \leq 0$, then the state is separable.

In the following, we analyze the dependence of the Simon function $S(t)$ and the logarithmic negativity $E_N(t)$ on time $t$ and temperature $T$ in the case of a thermal bath when the diffusion coefficients are given by equations (15). We consider two types of the initial Gaussian state: (i) separable and (ii) entangled.
(i) In Figure 1, we present the dependence of the function $S(t)$ on time $t$ and temperature $T$ for a separable initial Gaussian state, with the two modes initially prepared in their single-mode squeezed states (unimodal squeezed state). Therefore the initial covariance matrix is assumed to be of the form

$$
\sigma (0) = \frac{1}{2} \begin{pmatrix} 
\cosh r & \sinh r & 0 & 0 \\
\sinh r & \cosh r & 0 & 0 \\
0 & 0 & \cosh r & \sinh r \\
0 & 0 & \sinh r & \cosh r 
\end{pmatrix}, \quad (19)
$$

where $r$ denotes the squeezing parameter. We note that $S(t)$ becomes strictly positive after the initial moment of time ($S(0) = 0$), so that the initial separable state remains separable for all values of the temperature $T$ and for all times.

(ii) The evolution of an entangled initial state is illustrated in Figures 2 and 3, where we represent the dependence of the function $S(t)$ and the logarithmic negativity $E_N(t)$ on time $t$ and temperature $T$ for an entangled initial Gaussian state, assumed to be of the form of a two-mode vacuum squeezed state, with the initial covariance matrix given by

$$
\sigma (0) = \frac{1}{2} \begin{pmatrix} 
\cosh r & 0 & \sinh r & 0 \\
0 & \cosh r & 0 & -\sinh r \\
\sinh r & 0 & \cosh r & 0 \\
0 & -\sinh r & 0 & \cosh r 
\end{pmatrix}. \quad (20)
$$

We observe that for a non-zero temperature $T$, at a certain finite moment of time, which depends on $T$, $S(t)$ becomes zero and therefore the state becomes separable. This is the so-called phenomenon of entanglement sudden death. It corresponds to finite moment of time when the logarithmic negativity becomes zero. This phenomenon is in contrast to the quantum decoherence, during which the loss of quantum coherence is usually gradual [19, 34]. For $T = 0$, $S(t)$ remains strictly negative for finite times and tends asymptotically to 0 for $t \to \infty$. Therefore, only for zero temperature of the thermal bath the initial entangled state remains entangled for finite times and this state tends asymptotically to a separable one for infinitely large times. We note also that the dissipation favors the phenomenon of entanglement sudden death—with increasing dissipation parameter $\lambda$, entanglement sudden death happens earlier.
3.2. Asymptotic entanglement and quantum discord

On general grounds, one expects that the effects of decoherence are dominant in the long-time regime, so that no quantum correlations (entanglement) are expected to be left at infinity. Indeed, using the diffusion coefficients given by equations (15), we obtain from equation (11) the following elements of the asymptotic matrices $A(\infty)$ and $B(\infty)$:

\[
\begin{align*}
    m_{\omega_1} \sigma_{x,x}(\infty) &= \frac{\sigma_{p_x,p_x}(\infty)}{m_{\omega_1}} = \frac{1}{2} \coth \frac{\omega_1}{2kT}, \quad \sigma_{x,p_x}(\infty) = 0, \\
    m_{\omega_2} \sigma_{y,y}(\infty) &= \frac{\sigma_{p_y,p_y}(\infty)}{m_{\omega_2}} = \frac{1}{2} \coth \frac{\omega_2}{2kT}, \quad \sigma_{y,p_y}(\infty) = 0;
\end{align*}
\]

and of the entanglement matrix $C(\infty)$:

\[
\begin{align*}
    \sigma_{x,y}(\infty) = \sigma_{x,p_y}(\infty) = \sigma_{y,p_x}(\infty) = \sigma_{p_x,p_y}(\infty) = 0.
\end{align*}
\]

Then the Simon expression (13) takes the following form in the limit of large times (for $\omega_1 = \omega_2$):

\[
S(\infty) = \frac{1}{16} \left( \coth^2 \frac{\omega}{2kT} - 1 \right)^2,
\]

and, correspondingly, the equilibrium asymptotic state is always separable in the case of two non-interacting harmonic oscillators immersed in a common thermal reservoir.

In [26, 27, 34–36], we described the dependence of the logarithmic negativity $E_N(t)$ on the time and mixed diffusion coefficient for two harmonic oscillators interacting with a general environment. In the present case of a thermal bath, the asymptotic logarithmic negativity is given by (for $\omega_1 = \omega_2$)

\[
E_N(\infty) = -\log_2 \coth \frac{\omega}{2kT}.
\]

It depends only on the temperature, and does not depend on the initial Gaussian state. $E_N(\infty) < 0$ for $T \neq 0$ and $E_N(\infty) = 0$ for $T = 0$, and this confirms the previous statement that the asymptotic state is always separable.

4. Summary

In the framework of the theory of open quantum systems based on completely positive quantum dynamical
semigroups, we investigated the Markovian dynamics of the quantum entanglement for a subsystem composed of two non-interacting modes embedded in a thermal bath. We have presented and discussed the influence of the environment on the entanglement dynamics for different initial states. By using the Peres–Simon necessary and sufficient condition for separability of two-mode Gaussian states, we have described the evolution of entanglement in terms of the covariance matrix for Gaussian input states, for the case when the asymptotic state of the considered open system is a Gibbs state corresponding to two independent quantum harmonic oscillators in thermal equilibrium. The dynamics of the quantum entanglement strongly depends on the initial states and the parameters characterizing the environment (dissipation coefficient and temperature). For all values of the temperature of the thermal reservoir, an initial separable Gaussian state remains separable for all times. In the case of an entangled initial Gaussian state, entanglement suppression (entanglement sudden death) takes place for non-zero temperatures of the environment. Only for zero temperature of the thermal bath the initial entangled state remains entangled for finite times, but in the limit of infinite time it evolves asymptotically to an equilibrium state that is always separable. The time when entanglement is suppressed decreases with increasing the temperature and dissipation. We also described the time evolution of the logarithmic negativity, which characterizes the degree of entanglement of the quantum state, and it confirms that the asymptotic equilibrium state is always separable.
