Approximating Functional of Local Martingale Under the Lack of Uniqueness of Black-Scholes PDE

Qingshuo Song *

January 12, 2013

Abstract

When the underlying stock price is a strict local martingale process under an equivalent local martingale measure, Black-Scholes PDE associated with an European option may have multiple solutions. In this paper, we study an approximation for the smallest hedging price of such an European option. Our results show that a class of rebate barrier options can be used for this approximation. Among of them, a specific rebate option is also provided with a continuous rebate function, which corresponds to the unique classical solution of the associated parabolic PDE. Such a construction makes existing numerical PDE techniques applicable for its computation. An asymptotic convergence rate is also studied when the knocked-out barrier moves to infinity under suitable conditions.

Keywords. Black-Scholes PDE, Non-Uniqueness, Financial bubbles; Local martingales; Convergence rate;

1 Introduction

In a financial market equipped with the unique equivalent local martingale measure (ELMM) \( \mathbb{P} \), the smallest hedging price of an European option is the conditional expectation of the payoff with respect to the probability \( \mathbb{P} \), see [5, 7]. In contrast to the probabilistic representation, option price can be also characterized as the unique solution of its associated Black-Scholes PDE, provided that PDE has a unique classical solution.

The necessary and sufficient condition for the unique solvability of the parabolic PDE is that, the underlying stock price is Martingale process, see [1]. In other words, if the stock price is a strict local Martingale, then there exists multiple solutions for Black-Scholes PDE. Moreover, the option price may be one of the many solutions, see [4]. The difference of the multiple solutions of PDE is termed as financial bubbles, see [2, 1, 6] and the references

therein. In this work, we will consider the following problem proposed by Fernholz and Karatzas [5]:

(Q) How can one find a feasible numerical solution convergent to the option price under the lack of uniqueness of Black-Scholes PDE?

We first examine the existing numerical schemes on CEV model of Example 1, where the option price can be explicitly identified. There are typically two kinds of numerical schemes in this vein [11]. One is Monte Carlo method by discretizing the probability representation, the other is PDE numerical method by discretizing the truncated version of PDE.

Unfortunately, Example 2 and Example 3 shows that classical Euler-Maruyama approximation (for Monte Carlo method) and finite difference method (for PDE numerical method) leads to a strictly larger value than the desired option price. Motivated from these two examples, question (Q) boils down into the following two problems:

(Q1) Find a feasible approximation for a Monte Carlo method, and its convergence rate;
(Q2) Find a feasible approximation for PDE numerical method, and its convergence rate.

In short, this work intends to find a feasible approximation to the smallest superhedging price $V(x, t)$. It turns out that the value function can be obtained by a limit of a series of appropriate rebate option prices, which can be estimated by usual Monte Carlo method, see the details in Corollary 2. However, Corollary 2 may not be utilized for the approximation by PDE numerical method, since it may cause a discontinuity at the corner of the terminal-boundary datum. Therefore, a specific rebate option is proposed with its price continuous up to the boundary, so that its price corresponds to the unique classical solution of its associated parabolic PDE. Such a construction makes existing numerical PDE techniques applicable for computations, see Theorem 3.

The rest of the paper is outlined as follows. In the next section, we give precise formulation of the problem. Section 3 presents main results, and related proofs is relegated to Section 4 for the reader’s convenience. The last section summarizes the work.

2 Problem formulation

Throughout this paper, we use $K$ as a generic constant, and $\mathbb{R}^+ = (0, \infty)$, $\bar{\mathbb{R}}^+ = \mathbb{R}^+ \cup \{0\}$. If $A$ is a subset of $\mathbb{R} \times [0, T]$, then $C(A)$ denotes the set of all continuous real functions on $A$, $C^{2,1}(A)$ denotes a collection of all functions $\varphi : A \mapsto \mathbb{R}$ such that $\varphi_{xx}$ and $\varphi_t$ belong to $C(A)$. $D_\gamma(A)$ denotes the set of all measurable functions $\varphi : A \mapsto \bar{\mathbb{R}}^+$ satisfying growth condition

$$\varphi(x, t) \leq K(1 + |x|^{\gamma}), \ \forall (x, t) \in A. \quad (2.1)$$

$C_\gamma(A) = C(A) \cap D_\gamma(A)$ denotes the set of all continuous functions satisfying $\gamma$-growth. We also denote the parabolic domain $Q := \mathbb{R}^+ \times (0, T)$, truncated domain $Q_\beta := (0, \beta) \times (0, T)$, and $Q_\alpha^\beta := (\alpha, \beta) \times (0, T)$ for $0 < \alpha < \beta$.  

2
We consider a single stock in the presence of the unique equivalent local martingale measure (ELMM) \( P \), under which the deflated price process follows

\[
dX(s) = \sigma(X(s))dW(s), \quad X(t) = x \geq 0,
\]

(2.2)

where \( W \) is a standard Brownian motion with respect to a given probability space \( (\Omega, \mathcal{F}, P, \mathcal{F} = \{\mathcal{F}_s : s \geq t\}) \) satisfying usual conditions. We impose the following two conditions on \( f \) and \( \sigma \):

(A1) \( \sigma \) is locally H"older continuous with exponent \( \frac{1}{2} \) satisfying \( \sigma(x) > 0 \) for all \( x \in \mathbb{R}^+ \), \( \sigma(0) = 0 \).

(A2) \( f : \mathbb{R}^+ \rightarrow \mathbb{R}^+ \) is a \( C^\gamma(\mathbb{R}^+) \) payoff function for some \( \gamma \in [0, 1] \).

By [8, 5.5.11], the assumption (A1) on \( \sigma \) ensures there exists a unique strong solution of (2.2) with absorbing state at zero.

For a contingent claim \( f(X(T)) \) with a fixed maturity \( T > 0 \), the smallest hedging price has the form of

\[
V(x, t) = \mathbb{E}_{x, t}[f(X(T))]:= \mathbb{E}[f(X^{x, t}(T))|\mathcal{F}_t].
\]

(2.3)

In the above, we suppress the superscripts \((x, t)\) in \( X^{x, t} \), and write \( \mathbb{E}_{x, t}[\cdot] \) to indicate the expectation with respect to \( P \) computed under these initial conditions.

Recently, [4] shows that the value function \( V \) of (2.3) is the \( C^2(\mathbb{Q}) \cap C(\overline{\mathbb{Q}}) \) solution of \( BS(Q, f) \), where \( BS(Q, f) \) refers to Black-Scholes equation

\[
BS(Q, f) \begin{cases}
(E) & u_t + \frac{1}{2} \sigma^2(x)u_{xx} = 0 \text{ on } Q = \mathbb{R}^+ \times (0, T) \\
(TD) & u(x, T) = f(x) \text{ on } \forall x \in (0, \infty) \\
(BD) & u(0, t) = f(0) \text{ on } \forall t \in (0, T).
\end{cases}
\]

(2.4)

However, the next example taken from [2] shows that the value function \( V \) may not be the unique solution of \( BS(Q, f) \) when the deflated price process \( X \) is a strict local martingale.

**Example 1** (CEV model). Suppose the stock price follows a strict local martingale process \( dX(s) = X^2dW(s) \), with the initial \( X(t) = x > 0 \). Consider \( V(x, t) = \mathbb{E}_{x, t}[X(T)] \). Then, \( V \) can be computed explicitly as

\[
V(x, t) = x \left(1 - 2\Phi \left(- \frac{1}{x \sqrt{T - t}} \right) \right).
\]

(2.5)

One can verify \( V \) satisfies \( BS(Q, f) \). Another trivial solution is \( u(x, t) = x \).

Now, \( V \) is one of the possibly multiple solutions of \( BS(Q, f) \). With the existence of multiple solutions to PDE \( BS(Q, f) \), our question is

- If we use any of existing PDE numerical methods on \( BS(Q, f) \), or any of existing Monte-carlo methods on (2.3), does it converge to the desired value function among multiple solutions of PDE?
Unfortunately, the answer is NO in general. In fact, the next trivial example shows that the classical Monte Carlo method by Euler-Maruyama approximation does not lead to the desired value \( V(x, t) \) of (2.5) of Example 1.

**Example 2.** Consider the strong Euler-Maruyama (EM) approximation to Example 1 with step size \( \Delta \),

\[
X_{n+1}^\Delta = X_n^\Delta + \sigma(X_n^\Delta)(W(n\Delta + \Delta) - W(n\Delta)), \quad X_t^\Delta = x.
\]

Let \( X^\Delta(\cdot) \) be the piecewise constant interpolation of \( \{X_n^\Delta : n \geq 0\} \), i.e.

\[
X^\Delta(s) = X_{\lfloor s/\Delta \rfloor}^\Delta, \quad \forall s > 0.
\]

Since \( \{X_n^\Delta : n \geq 0\} \) is a martingale, the approximated value function simply leads to a wrong value

\[
V_\Delta(x, t) := \mathbb{E}_{x,t}[X_{\Delta}(T)] = \mathbb{E}_{x,t}[X_{(T-t)/\Delta}] = x > V(x, t). \quad \square
\]

Similar to Monte-carlo method, One can also prove that the finite difference method on PDE \( BS(Q, f) \) also leads to a wrong value.

**Example 3.** Black-Scholes PDE associated to the CEV model Example 1 is \( BS(Q, f) \) of (2.4) with \( \sigma(x) = x^2 \) and \( f(x) = x \). To use the finite difference method (FDM) in the above PDE, we shall truncate the domain and put artificial boundary conditions on the upper barrier \( \{(x, t) : 0 \leq t \leq T\} \) for large enough \( \beta > 0 \). As suggested by [11], we impose boundary conditions, which asymptotes the option price, i.e.

\[
u(\beta, t) = \beta, \quad \forall 0 \leq t \leq T.
\]

With step size \( \Delta^2 \) in space variable \( x \) and \( \Delta \) in time variable \( t \), one can easily check upward finite difference scheme backward in time yields trivial numerical solution \( u^\Delta(x, t) = x \) for any small \( \Delta > 0 \). \( \square \)

To the end, our work is to resolve the following question: How can one find a feasible approximation of this value function \( V \) of (2.3) in both Monte Carlo method and FDM? What is the convergence rate?

### 3 Main result

In this subsection, we present the main results, and the proofs will be relegated to the next section.
3.1 Approximation by Monte Carlo method

We consider the following up-rebate option prices: Suppose the up barrier is given by a positive constant $\beta > x > 0$ and stopping time $\tau^\beta$ (suppressing the initial condition $(x,t)$) is the first hitting time of the stock price $X(s)$ to the barrier $\beta$, i.e.

$$\tau^{x,t,\beta} = \inf\{s > t : X^{x,t}(s) \geq \beta\} \wedge T. \quad (3.1)$$

For some function $g$, let its payoff at $\tau^{x,t,\beta}$ consist of

1. rebate payoff $g(\beta)$, if $\tau^\beta < T$;
2. otherwise, terminal payoff $f(X(T))$.

Then, the rebate option price $V^\beta$ is of the form

$$V^\beta(x,t) = \mathbb{E}_{x,t}[g(\beta)1_{\{\tau^\beta < T\}} + f(X(T))1_{\{\tau^\beta = T\}}], \quad (3.2)$$

$V^\beta$ is a functional of $f$ and $g$, and we may write $V^{\beta,g,f}$ instead of $V^\beta$ whenever it needs an explicit emphasis on its dependence of $f$ and $g$. It turns out that the option price value of (2.3) can be obtained by a limit of a series of appropriate rebate option prices.

**Theorem 1.** Assume (A1-A2). Suppose the rebate payoff $g$ satisfies one of the following two conditions:

1. $g(x)$ is of sub-linear growth, i.e. $\lim_{x \to \infty} \frac{g(x)}{x} = 0$;
2. $g(x)$ is of linear growth, i.e. $\limsup_{x \to \infty} \frac{g(x)}{x} < \infty$, and $X^{x,t}$ is a martingale.

Then, we have the convergence for $V^\beta$ of (3.2),

$$\lim_{\beta \to \infty} V^\beta(x,t) = V(x,t).$$

In addition, if $g \in D_\eta(\mathbb{R}^+)$ with $\gamma \wedge \eta < 1$, then the convergence rate is the order of $1 - (\gamma \wedge \eta)$ as $\beta \to \infty$, i.e.

$$|(V - V^\beta)(x,t)| \leq K\beta^{-(1-(\gamma \wedge \eta))}, \forall x < \beta. \quad (3.3)$$

**Theorem 1** shows that Monte Carlo method on the expression $V^\beta$ of (3.2) actually leads to correct estimation of the option price $V$, provided that the rebate function $g$ is appropriately chosen. Among the many choices of $g$, the simplest one shall be taking $g \equiv 0$. Next result summarizes the above comments.

**Corollary 2.** Let

$$V^{\beta,0} = \mathbb{E}_{x,t}[f(X(T))1_{\{\tau^\beta = T\}}].$$

Then, $\lim_{\beta \to \infty} V^{\beta,0}(x,t) = V(x,t)$ point wisely in $x$ and $t$. Furthermore, if $f(x) = O(x^\gamma)$ with some constant $\gamma < 1$, then its convergence rate is

$$|(V - V^\beta)(x,t)| = O(\beta^{-1+\gamma}), \text{ as } \beta \to \infty.$$
In this below, we fix Monte Carlo method in Example 2 based on convergence result in Theorem 1.

Example 4. Let’s extend \( f : \mathbb{R}^+ \mapsto \mathbb{R} \) to \( f : \mathbb{R} \mapsto \mathbb{R} \) by \( f(x) = f(0) \) for \( x < 0 \). With \( X^\Delta(\cdot) \) of (2.6), let \( \tau^\beta_\Delta \) be the first hitting time of \( X^\Delta \) to the barrier \( \beta \). The modified Monte Carlo scheme to approximate \( V(x,t) \) of Example 2 is given by,

\[
V^\beta_{\Delta}(x,t) := \mathbb{E}_{x,t}\left[f(X^\Delta(T))1_{\{\tau^\beta_\Delta \geq T\}}\right].
\]

Corollary 2 implies that the rebate option price is convergent to the smallest hedging price, i.e.

\[ V^\beta(x,t) := \mathbb{E}_{x,t}[f(X(T))1_{\{\tau^\beta \geq T\}}] \rightarrow V(x,t) \quad \text{as } \beta \rightarrow \infty. \]

Note that \( X^\Delta(T) \rightarrow X(T) \) a.s. and \( |f(X^\Delta(T))1_{\{\tau^\beta \geq T\}}| \leq \max_{0 \leq x \leq \beta} f(x) \).

Hence, Bounded Convergence Theorem also implies that

\[ V_{\Delta}^\beta(x,t) \rightarrow V^\beta(x,t), \quad \text{as } \Delta \rightarrow 0. \]

As a result, the option price \( V(x,t) \) of (2.3) can be approximated by using Monte Carlo method on the above rebate options, i.e.

\[ \lim_{\beta \rightarrow \infty} \lim_{\Delta \rightarrow 0} V_{\Delta}^\beta(x,t) = V(x,t). \]

Regarding the estimation by Monte Carlo method, one may take the simplest choice \( g(\beta) \equiv 0 \) for the rebate payoff as of Corollary 2; see also [3]. However, Corollary 2 cannot be utilized the approximation by PDE numerical method, since it may cause a discontinuity at the corner \((\beta, T)\) of the terminal-boundary datum when \( f(\beta) \neq 0 \).

3.2 Approximation by PDE numerical method

For the above Monte Carlo method on (3.2), yet another to be mentioned is a drawback in the computation by PDE numerical methods due to the possible discontinuity of the boundary-terminal data.

To illustrate this issue, we write Black-Scholes PDE associated to the rebate option price \( V^\beta(x,t) \) of (3.2),

\[
\begin{cases}
  u_t + \frac{1}{2} \sigma^2(x) u_{xx} = 0 \quad \text{on } Q_\beta := (0, \beta) \times (0, T); \\
  u(x, T) = f(x), \quad \forall x \in [0, \beta]; \\
  u(0, t) = f(0), \quad u(\beta, t) = g(\beta), \quad \forall t \in (0, T).
\end{cases}
\]

Note that, PDE (3.5) has a discontinuous corner at the point \((\beta, T)\) if \( g(\beta) \neq f(\beta) \). Also recall that, the choice of \( g(\beta) = f(\beta) \) may not be possible, like in CEV model of Example 1.
It is well known that, if \( g(\beta) \neq f(\beta) \) and the boundary-terminal data is discontinuous, then one can not expect the unique solution of \((3.5)\) continuous up to the boundary. Furthermore, the discontinuity and the singularity at the corner propagate the numerical errors quickly throughout its entire domain for the numerical PDE methods, such as finite element method (FEM) or finite difference method (FDM), see more discussions in \([10]\) and the references therein. Therefore, the unique solvability and the regularity of the solution are crucial to make use of the existing PDE numerical methods.

To avoid this error propagation due to the discontinuity of the boundary-terminal data, we provide an alternative choice to \((3.2)\) by revising the terminal payoff: Consider a rebate option of barrier \( \beta \) with

1. zero rebate payoff, i.e. \( g(\beta) \equiv 0; \)
2. and a revised terminal payoff

\[
f(\beta)(x) = f(x) \{ x \leq \beta/2 \} + 2f(x)(\beta - x) \{ \beta/2 < x \leq \beta \}.
\]

(3.6)

In this case, the rebate option price \( \tilde{V}(x,t) = \mathbb{E}_{x,t}[f(\beta)(X(T))\mathbf{1}_{\{\tau = T\}}] \)

(3.7)

is associated to PDE

\[
\begin{align*}
(E)_{\beta} & \quad u_t + \frac{1}{2}\sigma^2(x)u_{xx} = 0 \quad \text{on} \quad Q_{\beta} := (0, \beta) \times (0, T); \\
(BD) & \quad u(0,t) = f(0), \quad u(\beta,t) = 0, \quad \forall t \in (0,T); \\
(TD)_{\beta} & \quad u(x,T) = f(\beta)(x), \quad \forall x \in [0,\beta].
\end{align*}
\]

(3.8)

Observe that, the revised terminal data \( f(\beta) \) not only makes the terminal-boundary data continuous at the corner \((\beta,T)\), but also preserves Hölder regularity of the original terminal data \( f \) regardless how large the value \( \beta \) is.

Although PDE \((3.3)\) is degenerate at \( x = 0 \), one can still has unique classical solution by utilizing Shauder’s interior estimate. Also, its solution is indeed equal to the revised rebate option price \( \tilde{V}(\beta) \) of \((3.7)\), see Lemma \([9]\). Moreover, by using comparison principle twice on two different truncated domains, one can show its unique solution \( \tilde{V}(\beta) \) must be convergent to the desired value \( V \) of \((2.3)\).

**Theorem 3.** Assume \((A1-A2)\). Then, \( \tilde{V}(\beta) \) of \((3.7)\) is the unique \( C^{2,1}(Q_{\beta}) \cap C(\overline{Q}_{\beta}) \) solution of PDE \((3.3)\), and

\[
\lim_{\beta \to \infty} \tilde{V}(\beta)(x,t) = V(x,t), \quad \forall (x,t) \in Q.
\]

In addition, if \( \gamma < 1 \) in \((A2)\), then the convergence rate is

\[
|\tilde{V}(\beta) - V|(x,t) \leq K\beta^{-1+\gamma}.
\]

Thanks to the Theorem \([8]\), one can use either well established FDM or FEM on PDE \((3.8)\) for a large \( \beta \) to estimate the smallest superhedging price.
4 Proof of main results

In this section, we will first characterize the value function $V$. Based on the properties of $V$, we can estimate $|V - V^\beta|$ to prove Theorem 1, and $|V - \bar{V}^\beta|$ to prove Theorem 3, respectively.

4.1 Characterization of the option price $V$

We have seen that the option price $V$ of (2.3) is one of the solutions of $BS(Q,f)$. To proceed, we need identify which solution corresponds to the option price $V$ among many. This enables us to establish the connection between parabolic partial differential equation $BS(Q,f)$ and probability representation (2.3).

Proposition 4. Assume (A1-A2). Then, value function $V$ of (2.3) is

1. the smallest lower-bounded $C^{2,1}(Q) \cap C_\gamma(Q)$ solution of $BS(Q,f)$.

2. the unique $C^{2,1}(Q) \cap C(Q)$ solution of $BS(Q,f)$ if and only if $\sigma$ satisfies

$$\int_1^\infty \frac{x}{\sigma^2(x)} dx = \infty. \tag{4.1}$$

Proof. Theorem 3.2 of [4] shows that $V$ is a $C^{2,1}(Q) \cap C(Q)$ solution of $BS(Q,f)$. Applying super-martingale property of $X(T)$ and Jensen’s inequality, the next derivation shows that $V \in C_\gamma(Q)$,

$$V(x,t) = \mathbb{E}_x,t[f(X(T))] \leq K(1 + \mathbb{E}_x,t[X^\gamma(T)]) \leq K(1 + x^\gamma).$$

For the necessary and sufficient condition on uniqueness, we refer the proof to [1]. It remains to show $V$ is the smallest lower bounded solution. Sometimes, we use $X$ to denote $X^{x,0}$ without ambiguity in this proof. Note that, by path-wise uniqueness of the solution to (2.2)

$$Y(t) \triangleq V(X^{x,0}(t),t) = \mathbb{E}[f(X^{x,0}(t),t)|\mathcal{F}_t] = \mathbb{E}[f(X^{x,0}(T))|\mathcal{F}_t]$$

is a martingale process. Suppose $\hat{V} \in C^{2,1}(Q) \cap C(Q)$ is an arbitrary lower bounded solution of $BS(Q,f)$, then Ito’s formula applying to $\hat{Y}(t) \triangleq \hat{V}(X(t),t)$ leads to

$$\hat{Y}(t) = V(X(0),0) + \int_0^t \hat{V}_x(X(s),s)\sigma(X(s))dW(s),$$

and $\hat{Y}(t)$ is a lower bounded local martingale, hence is a super-martingale. Therefore, we have

$$\hat{Y}(0) \geq \mathbb{E}[\hat{Y}(T)] = \mathbb{E}[f(X(T))] = Y(0)$$

and this implies

$$\hat{V}(x,0) \geq V(x,0).$$

We can similarly prove for $\hat{V}(x,t) \geq V(x,t)$ for all $t$. \qed
Proposition 5. Assuming (A1-A2), BS(Q, f) only admits non-negative solution in the space of lower bounded $C^{2,1}(Q) \cap C(\overline{Q})$ functions.

Proof. Proposition 4 shows that $V$ is the smallest lower-bounded solution of PDE. Since $V \geq 0$ by definition of (2.3), it implies any lower-bounded solution $u$ satisfies $u \geq V \geq 0$.

In Example 1 we have seen that $BS(Q, f)$ of CEV model has multiple solutions. We continue this model to demonstrate Proposition 5, a solution smaller than $V$ must be unbounded from below.

Example 5. By Proposition 4 the explicit solution $V \geq 0$ of (2.5) in CEV model smallest lower-bounded solution of $BS(Q, f)$. In fact one can find,

$$v(x, t) = x \left( 1 - \lambda \Phi \left( -\frac{1}{x \sqrt{T - t}} \right) \right), \lambda > 2$$

is a smaller solution, i.e. $v \leq V$ in $Q$. However, $v$ is not lower-bounded, i.e. $v(x, t) \to -\infty$ as $x \to \infty$.

4.2 Proof of Theorem 1

Recall that the domain of the value function $V$ is given on the domain $Q$ of (2.4), and its related truncated domain $Q^\beta$ is given by (3.5). Let $\varphi : \overline{Q} \to \mathbb{R}^+$ be a measurable function. We introduce the truncated value function $V^\beta, \varphi$ for convenience,

$$V^\beta, \varphi(x, t) = \begin{cases} 
\mathbb{E}_{x,t}[\varphi(X(\tau^\beta), \tau^\beta)], & \forall (x, t) \in \overline{Q}_\beta, \\
\varphi(x, t), & \text{Otherwise.}
\end{cases} \tag{4.2}$$

where the stopping time $\tau^\beta$ of (3.1) is the first hitting time to the barrier $\beta$. By the above definition,

$$V^\beta, \varphi_1(x, t) = V^\beta(x, t)$$

for the $V^\beta$ of (3.2), if we set

$$\varphi_1(x, t) = g(x) 1_{\{t < T\}} + f(x) 1_{\{t = T\}}. \tag{4.3}$$

With the above setup, to prove Theorem 1 our goal is to estimate $|V^\beta, \varphi_1 - V|$ as $\beta \to \infty$ with $\varphi_1$ of (4.3) and the constraint on $g$ given in Theorem 1. We emphasize here, $\varphi_1$ may not be continuous up to the boundary, i.e. $\varphi_1 \notin C(\overline{Q})$ when $g(x) < f(x)$ for some $x > 0$.

Lemma 6. Assume (A1-A2). Then,

1. $V(x, t) = V^\beta, V(x, t)$ for all $0 < x < \beta$.

2. If $\varphi, \psi : \overline{Q} \to \mathbb{R}^+$ are two measurable functions satisfying $\varphi \geq \psi$ on $\partial^*Q_\beta$, then

$$V^\beta, \varphi \geq V^\beta, \psi, \forall \beta > 0.$$
Proof. $X^{x,t}$ is the unique strong solution of (2.2) due to (A1). Therefore, the conclusion follows from the following simple derivation using tower property and strong Markov property:

\begin{align*}
V(x,t) &= \mathbb{E}[f(X^{x,t}(T)) | \mathcal{F}_t] \\
&= \mathbb{E}[\mathbb{E}[f(X^{x,t}(T)) | \mathcal{F}_{\tau^\beta}] | \mathcal{F}_t] \\
&= \mathbb{E}[\mathbb{E}[f(X^{x,t}(\tau^\beta), \tau^\beta(T)) | \mathcal{F}_{\tau^\beta}] | \mathcal{F}_t] \\
&= \mathbb{E}[V(X(\tau^\beta), \tau^\beta) | \mathcal{F}_t] \\
&= V^{\beta,V}(x,t).
\end{align*}

Monotonicity of $V^{\beta,\varphi}$ in $\varphi$ follows directly from the definition of $V^{\beta,\varphi}$ of (4.2). \(\square\)

It is noted that, two results of Lemma 6 correspond to uniqueness and comparison principle of its associated PDE. However, we provide the probabilistic proof Lemma 6, since we want to cover potentially discontinuous function $\varphi_1$ of (4.3), in which uniqueness may not remain true.

Lemma 7. Assume (A1-A2) and $g \geq 0$. Then, $V^{\beta,\varphi_1}$ defined by (4.2) and (4.3) satisfies

\[ \lim_{\beta \to \infty} V^{\beta,\varphi_1}(x,t) \geq V(x,t). \]

In addition, equality holds in the above if and only if

\[ \lim_{\beta \to \infty} \mathbb{E}_{x,t}[g(\beta)1_{\{\tau^\beta < T\}}] = 0 \quad (4.4) \]

Proof. We start with the following observation: The solution $X := X^{t,x}$ of (2.2) does not explode almost surely by [8, 5.5.3], i.e.

\[ \lim_{\beta \to \infty} \tau^\beta = T, \quad \text{a.s.-}\mathbb{P} \quad (4.5) \]

Due to this fact together with Monotone Convergence Theorem, we obtain following identities:

\[ \lim_{\beta \to \infty} \mathbb{E}_{x,t}[f(X(T))1_{\{\tau^\beta = T\}}] = \mathbb{E}_{x,t} \left[ \lim_{\beta \to \infty} f(X(T))1_{\{\tau^\beta = T\}} \right] = \mathbb{E}_{x,t}[f(X(T))] = V(x,t). \quad (4.6) \]

By the definition of $\varphi_1$ of (4.3), this results in

\[ \lim_{\beta \to \infty} V^{\beta,\varphi_1}(x,t) \]

\[ = \lim_{\beta \to \infty} \mathbb{E}_{x,t}[\varphi_1(X(\tau^\beta), \tau^\beta)1_{\{\tau^\beta < T\}}] + \lim_{\beta \to \infty} \mathbb{E}_{x,t}[\varphi_1(X(\tau^\beta), \tau^\beta)1_{\{\tau^\beta = T\}}] \]

\[ = \lim_{\beta \to \infty} \mathbb{E}_{x,t}[\varphi_1(\beta, \tau^\beta)1_{\{\tau^\beta < T\}}] + \lim_{\beta \to \infty} \mathbb{E}_{x,t}[f(X(T))1_{\{\tau^\beta = T\}}] \]

\[ = \lim_{\beta \to \infty} \mathbb{E}_{x,t}[g(\beta)1_{\{\tau^\beta < T\}}] + V(x,t). \]

Rearranging the above identity, we have

\[ V(x,t) = \lim_{\beta \to \infty} V^{\beta,\varphi_1}(x,t) - \lim_{\beta \to \infty} \mathbb{E}_{x,t}[g(\beta)1_{\{\tau^\beta < T\}}]. \quad (4.7) \]

Note that three terms in (4.7) are all non-negative. Hence, $\lim_{\beta \to \infty} V^{\beta,\varphi_1}(x,t) \geq V(x,t)$ and equality holds if and only if (4.4) holds. \(\square\)
As mentioned in (4.5), the solution \( X^{x,t} \) of (2.2) does not explode almost surely, and this can be rewritten as
\[
P(\tau^{x,t,\beta} < T) \to 0 \text{ as } \beta \to \infty.
\]
An interesting question about this is that, how fast does the above probability converge to zero? The answer to this question is indeed useful to obtain the convergence rate of the truncated approximation.

**Proposition 8.** Fix \((x,t) \in Q\) and assume (A1-A2). As \( \beta \to \infty \), stopping time \( \tau^{x,t,\beta} \) of (3.1) satisfies
1. \( P\{\tau^{x,t,\beta} < T\} = O(1/\beta) \).
2. Moreover, \( P\{\tau^{x,t,\beta} < T\} = o(1/\beta) \) if and only if \( \{X^{t,x}(s) : t \leq s \leq T\} \) is a martingale.

**Proof.** By taking \( g(x) = f(x) = x \) in (4.7),
\[
\lim_{\beta \to \infty} E_{x,t}[X(\tau^x)] = \lim_{\beta \to \infty} \beta P\{\tau^{x,t,\beta} < T\} + E_{x,t}[X(T)].
\]
For all \( \beta > x \), since \( \{X^{x,t}(\tau^\beta \wedge s) : s > t\} \) is a bounded local martingale, hence it is martingale. So, \( E_{x,t}[X(\tau^x)] = x \) for all \( \beta > x \). Rearranging the above identity, we have
\[
\lim_{\beta \to \infty} \beta P\{\tau^{x,t,\beta} < T\} = x - E_{x,t}[X(T)]
\]
(4.8) implies
1. Since \( E_{x,t}[X(T)] \geq 0, \lim_{\beta \to \infty} \beta P\{\tau^{x,t,\beta} < T\} \leq x < \infty \), which shows \( P\{\tau^{x,t,\beta} < T\} = O(1/\beta). \)
2. \( \{X^{t,x}(s) : t \leq s \leq T\} \) is a martingale if and only if \( x = E_{x,t}[X(T)] \), if and only if \( P\{\tau^{x,t,\beta} < T\} = o(1/\beta) \).

Finally, we are now ready fo the proof of Theorem 1.

**Proof of Theorem 1.** We first show its convergence, then obtain convergence rate.

1. Regarding its convergence, it is enough to verify (4.4) by Lemma 7. Note that
\[
\lim_{\beta \to \infty} \mathbb{E}_{x,t}\left[g(\beta) \mathbb{1}_{\{\tau^\beta < T\}}\right] \leq \lim_{\beta \to \infty} \frac{g(\beta)}{\beta} \lim_{\beta \to \infty} \beta P\{\tau^{x,t,\beta} < T\}.
\]
(a) If \( g \) is of sub-linear growth, then \( \lim_{\beta \to \infty} \frac{g(\beta)}{\beta} = 0 \). Hence, (4.4) holds due to the first result of Proposition 8.
(b) On the other hand, if $X^{t,x}$ is a martingale, then we have $\lim_{\beta \to \infty} \beta \mathbb{P}\{\tau^{x,t,\beta} < T\} = 0$ from the second result of Proposition 5 and Proposition 14 remains true provided that $g$ is of linear growth.

2. Since $V(x, t) = V^\beta(V(x, t)$ for all $\beta > x$ by Lemma 6, we have the following identity:

$$(V - V_{\beta,\varphi_1})(x, t) = (V_{\beta} - V_{\beta,\varphi_1})(x, t) = \mathbb{E}[(V - \varphi_1)(X(\tau^\beta), \tau^\beta)1_{\{\tau^\beta < T\}}].$$

Setting $\bar{V} := \sup_{t \in [0,T]} V(x, t)$, we can rewrite

$$|V - V_{\beta,\varphi_1}|(x, t) \leq (|\bar{V}| + |g|)(\beta)\mathbb{E}[1_{\{\tau^\beta < T\}}].$$

(4.9)

Since $V \in C^1(\mathbb{R}^+)$ by Proposition 4 and $g \in D^\eta(\mathbb{R}^+)$, we have $|V + g| \in D^{\gamma \vee \eta}(\mathbb{R}^+)$. Hence, write (4.9) by Proposition 8

$$|V - V_{\beta,\varphi_1}|(x, t) \leq (|\bar{V}| + |g|)(\beta)O(1/\beta) \leq K\beta^{(\gamma \vee \eta) - 1},$$

which finally results in (3.3).

\[\square\]

4.3 Proof of Theorem 3

**Lemma 9.** Assume (A1-A2). Then $\bar{V}^\beta$ of (4.2) is the unique solution of (3.8) in the space of $C^{2,1}(Q_\beta) \cap C(\overline{Q_\beta}).$

**Proof.** Fix $(x, t) \in Q_\beta$. Take $\alpha \in (0, x/2)$. Recall $Q_\alpha^\beta = Q_\beta \cap (\overline{Q_\alpha})^c$ be an open set. Also define

$$\tau^{\alpha,\beta} = \inf\{s > t : (X^{x,t}(s), s) \notin Q_\alpha^\beta\}.$$

Due to the uniform ellipticity,

$$V^{\alpha,\beta}(x, t) := \mathbb{E}_{x,t}[f^\beta(X(\tau^{\alpha,\beta}))]$$

is the unique classical solution of

$$\begin{cases}
  u_t + \frac{1}{2}\sigma^2(x)u_{xx} = 0, & \text{on } Q_\alpha^\beta = (\alpha, \beta) \times (0, T) \\
  u(\beta, t) = 0, \ u(\alpha, t) = f^\beta(\alpha), & \forall t \in (0, T) \\
  u(x, T) = f^\beta(x), & \forall x \in [\alpha, \beta].
\end{cases}$$

(4.11)

If we restrict $V^{\alpha,\beta}$ on the subdomain $Q_{\beta}^{x/2}$, it solves following PDE uniquely,

$$\begin{cases}
  u_t + \frac{1}{2}\sigma^2(x)u_{xx} = 0, & \text{on } Q_{\beta}^{x/2} = (x/2, \beta) \times (0, T) \\
  u(\beta, t) = 0, \ u(x/2, t) = V^{\alpha,\beta}(x/2, t), & \forall t \in (0, T) \\
  u(x, T) = f^\beta(x), & \forall x \in [x/2, \beta].
\end{cases}$$

(4.12)
Furthermore, by using Shauder estimate Theorem 4.9 together with Theorem 5.9 of [9], one can have estimate on weighted Hölder norm, i.e.

$$|V^{\alpha,\beta}|_{2.5,Q^{\alpha,\beta}_{x/2}}^* \leq K|V^{\alpha,\beta}|_{0,Q^{\alpha,\beta}_{x/2}}$$

for some constant $K$ independent to $\alpha$. On the other hand, by definition (4.10), we have

$$|V^{\alpha,\beta}|_{0,Q^{\alpha,\beta}_{x/2}} \leq \sup_{x \in [0,\beta]} |f^\beta(x)| \leq K$$

for some $K$ independent to $\alpha$. Let

$$d = \frac{1}{2} \min \{x, \beta - x, t, T - t\},$$

which must be less than the minimum distance of $x$ to any point in the parabolic boundary $\partial^* Q^{\alpha,\beta}_x$. Consider a neighborhood of $x$ given by $N_x(d) := (x - r, x + r) \times (t - r, t + r)$. By definition of the weighted norm (Page 47 of [9]), we finally have the following $\alpha$-uniform estimate on $N_x(d)$,

$$|V^{\alpha,\beta}|_{2.5,N_x(d)} \leq |V^{\alpha,\beta}|_{2.5,Q^{\alpha,\beta}_x}^* \leq K$$

Therefore, Arzela-Ascoli Theorem implies that there exists a subsequence of $\{V^{\alpha,\beta} : \alpha \in (0, x/2)\}$, which is uniformly convergent to a function $u$ on $N_x(d)$, i.e.

$$V^{\alpha,\beta} \to u \text{ as } \alpha \to 0, \text{ uniformly on } N_x(d).$$

The uniform convergence implies that the limit function is $u \in C^{2,1}(N_x(d))$. Using the facts of almost sure convergence $\tau^{\alpha,\beta} \to \tau^\beta$, together with dominated convergence theorem, one can check that

$$\lim_{\alpha \to 0} V^{\alpha,\beta}(x, t) = \mathbb{E}_{x,t}[\lim_{\alpha \to 0} f^\beta(X(\tau^{\alpha,\beta}))] = \tilde{V}^\beta(x, t), \text{ pointwisely}$$

Hence, $V^\beta = u$ solves $(E)_\beta$ of (3.8) in the classical sense. By bounded convergence theorem, one can also show $\tilde{V}^\beta(x, t) \in C(\overline{Q}_\beta)$ from the facts

$$\lim_{x \to \beta} \tilde{V}^\beta(x, t) = 0, \lim_{x \to 0} \tilde{V}^\beta(x, t) = f(0), \lim_{t \to T} \tilde{V}^\beta(x, t) = f(x), \quad (4.13)$$

Thus, we conclude $\tilde{V}^\beta$ is the classical solution of (3.8). Moreover, strong solution satisfies maximum principle, and hence the uniqueness follows from Corollary 2.4 of [9].

Now, we are ready to prove Theorem 3.

**Proof of Theorem 3.** $\tilde{V}^\beta$ is the unique solution of (3.8) by Lemma 9. Fix $(x_0, t_0) \in Q$ and $\beta > 2x_0$. We will use comparison principle of Lemma 6 twice to obtain the desired results. Define $\varphi_2 : \overline{Q} \to \mathbb{R}$ by

$$\varphi_2(x, t) = f(x) \mathbf{1}_{\{t = T\}}.$$
Since $\varphi_2(x,t) \leq \hat{V}^\beta$ on $\partial^* Q_{\beta/2}$, we can apply Lemma 4 on $Q_{\beta/2}$ to obtain $V^{\beta/2, \varphi_2}(x_0, t_0) \leq \hat{V}^\beta(x_0, t_0)$. Similarly, since $\hat{V}^\beta \leq \varphi_2(x,t)$ on $\partial^* Q_{\beta}$ by its definition, we apply Lemma 4 on $Q_{\beta}$ to obtain $V^{\beta, \varphi_2}(x_0, t_0) \geq \hat{V}^\beta(x_0, t_0)$. Thus, we have inequality

$$V^{\beta/2, \varphi_2}(x_0, t_0) \leq \hat{V}^\beta(x_0, t_0) \leq V^{\beta, \varphi_2}(x_0, t_0).$$

Taking $\lim_{\beta \to \infty}$ in the above inequality and using Theorem 1, all three terms shall converge to the same value $V(x_0, t_0)$. The rate of the convergence is the combined result of (4.14) and (3.3).

5 Further remarks

This paper studies an approximation to the smallest hedging price of European option using rebate options. From mathematical point of view, this work concerns on the approximation of the value function $V$ of (2.3) by truncating the domain $Q$ and imposing suitable Cauchy-Dirichlet data $g$.

The main result on the convergence Theorem 1 provides that, if the function $g$ is chosen to satisfy sublinear growth in $x$ uniformly in $t \in [0, T)$, then the truncated value $V^{\beta, g}$ converges to $V$. This enables practitioners to adopt EM methods on big enough truncated domain $Q_{\beta}$ to get a close value of $V$, as demonstrated in Example 4.

On the other hand, to adopt numerical PDE techniques, continuous Cauchy-Dirichlet data is desired to get a good approximation. However, if the payoff $f$ is given as of a linear growth, $g$ is taken as of a sublinear growth in $x$ for the purpose of the convergence by Theorem 1 then it’s not possible to have a continuous solution of Black-Scholes PDE. Alternatively, we provide a continuous Cauchy-Dirichlet data by modifying the terminal payoff appropriately.
