Abstract

**Background:** MicroRNAs have been recognized as critical regulators for the osteoblastic lineage differentiation of human adipose-derived stem cells (hASCs). Previously, we have displayed that silencing of miR-137 enhances the osteoblastic differentiation potential of hASCs partly through the coordination of lysine-specific histone demethylase 1 (LSD1), bone morphogenetic protein 2 (BMP2), and mothers against decapentaplegic homolog 4 (SMAD4). However, still numerous molecules involved in the osteogenic regulation of miR-137 remain unknown. This study aimed to further elucidate the epigenetic mechanisms of miR-137 on the osteogenic differentiation of hASCs.

**Methods:** hASCs transfected with miR-137 overexpression or knockdown lentiviruses were used to assess the osteogenic capacity by testing the alkaline phosphatase activity, matrix mineralization degree, relative expression level of osteogenesis-associated genes and ectopic osteogenesis in nude mice. Dual-luciferase reporter assay was performed to examine the targeting of the 3' untranslated region (3' UTR) of NOTCH1 by miR-137. Interrelationships of signaling pathways of NOTCH1-hairy and enhancer of split 1 (HES1), LSD1, and BMP2-SMAD4 were thoroughly investigated by separate knockdown of NOTCH1, LSD1, and BMP2.

**Results:** We confirmed that miR-137 directly targeted the 3' UTR of NOTCH1 while positively regulated HES1. After knocking down NOTCH1 or BMP2 individually, we found that these two signals formed a positive feedback loop and activated LSD1. In addition, LSD1 knockdown induced the expression of NOTCH1 while suppressed HES1.

**Conclusions:** Collectively, we proposed a NOTCH1/LSD1/BMP2 co-regulatory signaling network to elucidate the modulation of miR-137 on the osteoblastic differentiation of hASCs, thus providing mechanism-based rationale for miRNA-targeted therapy of bone defect.

**Background**

As we know, human adipose-derived stem cells (hASCs) have multilineage differentiation potentials and good application prospects for bone regeneration [1–3] because of their abundant sources and easy access for clinical uses [4]. Though plenty of signaling pathways, such as Wnt/β-catenin signal [5], glycogen synthase kinase 3 signal [6], bone morphogenetic protein (BMP) signal [7–9], NOTCH signal [10, 11] and extracellular regulated protein kinases signal [7, 12, 13] have been demonstrated to dominate osteoblastic differentiation of hASCs, considerable research is still necessary to reveal intricate interactions between various signals and make further advances in hASC-based cell therapy.

MicroRNAs (MiRNAs) are a class of endogenous and highly conserved small non-coding single-stranded RNAs, which mediate post-transcriptional gene regulation [14] and play crucial roles in the proliferation and osteogenic differentiation of hASCs [5, 10, 15–18]. MiR-137 has been manifested its anti-tumor activity in multiple malignancies, such as glioblastoma [19], melanoma [20], multiple myeloma [21], non-small cell lung cancer [22] and endometrial cancer [23]. In neural development, several studies confirm
that miR-137 regulates cell proliferation, differentiation [24–28], and neuronal maturation [29–31] in adult or mouse stem cells. Nevertheless, during the process of hASCs differentiating into osteoblastic lineage, the functions and epigenetic mechanisms of miR-137 have not been investigated except for our previous study [32], in which we disclose part of the mechanisms as the coordination between lysine-specific histone demethylase 1 (LSD1) and BMP2-mothers against decapentaplegic homolog 4 (SMAD4) pathway. Considering that the relationships of osteogenesis-associated signals are complex and diverse and massive molecules participating in the LSD1/BMP2/SMAD4 network remain unascertained, we need to further clarify the regulatory mechanisms of miR-137 on the osteogenesis.

NOTCH signal is a fundamental pathway in bone remodeling and skeletal homeostasis [33–35]. Hairy and enhancer of split 1 (HES1), a downstream molecule of NOTCH [36], is responsible for the actions of NOTCH in the skeleton, even though its osteogenic effects are cell type-specific and context-dependent. By interacting with runt-related transcription factor 2 (RUNX2), HES1 induces osteopontin promoter [37]. But HES1 binds to the osteocalcin (OCN) promoter and suppresses its transcription in osteoblastic cells [38]. HES1 inactivation not only increases the femoral length and trabecular number in the limb bud of transgenic mice, but also enhances mineral apposition rate and suppresses bone resorption in osteoblasts [39]. NOTCH1 has emerged as a target of miR-137 in human renal mesangial cells [40], retinal ganglion cells [41], neurons [42], non-small cell lung cancer cells [43] and breast cancer cells [44], but whether it is directly inhibited by miR-137 has not yet been identified in hASCs. In small cell lung cancer cells, NOTCH1 pathway is activated by LSD1 inhibitor and suppressed due to the binding of LSD1 [45]. Additionally, the induction of NOTCH signal impairs the activation of BMP pathway and the osteoblastic differentiation of dental follicle cells [46]. In contrast, NOTCH1 upregulates BMP2 expression in human aortic valve interstitial cells through the stimulation of NF-κB [47]. Our previous study confirmed that miR-137 knockdown induced BMP2-SMAD4 pathway through the downregulation of LSD1 dependently or independently [32], which coincides with the studies stating that LSD1 inhibition leads to increased BMP2 expression [48, 49]. Accordingly, we postulate a signaling network entailing NOTCH1-HES1, LSD1 and BMP2-SMAD4 pathways to unveil the miR-137 modulation on the osteogenesis of hASCs.

This study identified the interactions of miR-137 and its downstream genes and revealed that the co-regulatory signaling network of NOTCH1/LSD1/BMP2 mediated by miR-137 negatively modulated the osteogenesis of hASCs, suggesting that miR-137 might be applied as a promising therapeutic target for bone regeneration.

**Methods**

**Mice**

The animal experiments were conducted in strict conformity with the guidelines of Animal Welfare Committee of Health Science Center in Peking University (LA2019019). Male, 5-week-old BALB/c-nu/nu
nude mice (Charles River, Wilmington, MA, USA) were randomly assigned to 3 groups (n = 6 per group) and maintained with specific pathogen-free conditions.

**Cell lines**

The hASCs isolated from three separate donors were purchased in ScienCell Research Laboratories (Carlsbad, CA, USA). For each donor, the *in vitro* cell experiments were performed at least three times individually. For proliferation culture, cells were maintained in proliferation medium (PM), containing Dulbecco's modified Eagle medium (Thermo Fisher Scientific, Rockford, IL, USA), 1% (v/v) penicillin/streptomycin (Thermo Fisher Scientific) and 10% (v/v) fetal bovine serum (ExCell Bio, Shanghai, China). When the cells reached 70-80% confluence, osteoinduction was performed by adding osteogenic medium (OM), which contained the above culture medium for promoting proliferation, 100 nM dexamethasone (Sigma-Aldrich), 0.2 mM L-ascorbic acid (Sigma-Aldrich) and 10 mM β-glycerophosphate (Sigma-Aldrich). The cell culture conditions were 37°C with 5% CO₂ and 100% relative humidity.

**Lentivirus transfection**

Recombinant lentiviruses carrying green fluorescent protein (GFP)-tagged plasmid vectors of negative control (NC), miR-137 overexpression (miR-137), miR-137 knockdown (anti-miR-137), NOTCH1 shRNA (anti-NOTCH1), LSD1 shRNA (anti-LSD1), and BMP2 shRNA (anti-BMP2) (Additional file 3: Table S1) were produced and packaged by GenePharma (Suzhou, Jiangsu, China). Lentiviral transfection of hASCs were conducted at a multiplicity of infection of 100 for 24 h with the presence of 5 mg/mL polybrene, and then selected by 1 μg/ml puromycin (Sigma-Aldrich). The transfection rates of lentiviruses were estimated by counting the number of GFP-tagged cells and total cells with an inverted fluorescence microscope (TE2000-U, Nikon, Tokyo, Japan).

**Alkaline phosphatase (ALP) staining and quantification**

After 7 days of culture in PM or OM, the hASCs were used for ALP staining and activity test according to the published protocol [10]. ALP staining was operated following the BCIP/NBT staining kit (Beyotime, Shanghai, China) instructions. For the quantitative tests of ALP activities, cells were washed with phosphate buffer saline (PBS) and 1% Triton X-100 (Solarbio, Beijing, China), then scraped in Milli-Q water and subjected to three cycles of freezing and thawing. By employing the BCA method and the pierce BCA protein assay kit (Thermo Fisher Scientific), total protein was read at 562 nm and computed with a bovine serum albumin standard curve according to the manufacturer’s protocol. Afterwards, ALP activity was detected at 520 nm applying an alkaline phosphatase assay kit (Jiancheng, Nanjing, Jiangsu, China) and finally normalized to the total protein concentrations of cells.

**Alizarin red S (ARS) staining and quantification**

After 14 days of culture in PM or OM, the hASCs were applied to detect the matrix mineralization. Following being fixed with 95% ethanol for 30 min, cells were soaked in 1% ARS staining solution (pH 4.2;
Sigma-Aldrich, St. Louis, MO, USA) for 20 min at room temperature. To assess the degree of mineralization, stained areas of each well were separately dissolved in 100 mM cetylpyridinium chloride (Sigma-Aldrich) for 1 h and the absorbances were detected at 562 nm. Finally, the relative ARS intensity was normalized to the total protein concentrations of cells.

**RNA extraction, reverse transcription, and quantitative real-time polymerase chain reaction (qRT-PCR)**

After 3, 7, and 14 days of culture in PM or OM respectively, total RNA of cells was isolated with TRIzol (Invitrogen, Carlsbad, CA, USA) and synthesized into the first-strand cDNA using a reverse transcription system (Takara, Tokyo, Japan). All the transcripts were quantified using the FastStart universal SYBR green master (ROX) (Roche, Indianapolis, IN, USA) and a 7500 real-time PCR detection system (Applied Biosystems, Foster City, CA, USA). Relative expression levels of mRNA and miRNA were normalized to GAPDH mRNA and U6 snRNA, respectively. The sequences of the primers employed were listed in Additional file 4: Table S2.

**Western blotting**

The hASCs were rinsed with ice PBS three times and immersed in RIPA buffer (HuaxingBio, Beijing, China) mixed with protease inhibitor cocktail (HuaxingBio). The pierce BCA protein assay kit (Thermo Fisher Scientific) was used to determine the protein concentration. A 25 μg sample of protein was added and separated by 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis, then followed by transfer to the polyvinylidene difluoride membranes (Millipore, Bedford, MA, USA). Strips on the membranes were blocked with 5% nonfat dry milk (BioRuler, Danbury, CT, USA) for 1 h at room temperature, incubated overnight at 4°C with primary antibodies at a dilution of 1:1000, and then for 1 h at room temperature with goat anti-rabbit secondary antibodies labeled with horseradish peroxidase (ZSGB-BIO, Beijing, China; ZB-2301) at a dilution of 1:10000. The primary antibodies used were as follows: anti-GAPDH (ZSGB-BIO; TA-08), anti-NOTCH1 (Cell Signaling Technology, Beverly, MA, USA; 3608S), anti-HES1(Abcam, Cambridge, UK; ab108937), anti-LSD1 (Cell Signaling Technology; 2139S), anti-BMP2 (Abcam; ab14933), anti-SMADA4 (Abcam; ab40759) and anti-RUNX2 (Cell Signaling Technology; 12556). Relative band intensities were measured with the ImageJ software.

**Dual-luciferase reporter assay**

The 3' untranslated region (3' UTR) alignments of the target regions in NOTCH1 were predicted by TargetScan and RNA22. Reporter vectors were constructed based on the previous method [32]. The 3' UTR sequences of NOTCH1, which contained the possible binding sites of miR-137, were PCR amplified and then inserted into pEZX-MT06 vectors (GeneCopoeia, Rockville, MD, USA) to create NOTCH1-WT (wild-type NOTCH1) luciferase reporter plasmids. Mutated forms were generated by site-directed mutagenesis (GeneCopoeia) and named NOTCH1-MT (mutant-type NOTCH1) luciferase reporter plasmids. For luciferase assay, the hASCs were planted on 24-well culture plates with a density of 5 × 10^4/well and co-transfected with 1 μg NOTCH1-WT or -MT plasmids, 100 nM NC or miR-137 mimics, and lipofectamine 3000 (Invitrogen). The luciferase activities were examined by a dual-luciferase reporter
assay system (Promega, Madison, WI, USA) 48 h later, and standardized to renilla luciferase activity for each transfected well.

**Heterotopic osteogenesis examinations in vivo**

After the transfection with NC, miR-137 and anti-miR-137 lentiviruses, hASCs of the third passage were maintained in PM for 1 week, collected and incubated with auto-setting calcium phosphate cement (ACPC; Rebone, Shanghai, China) for 1 h at 37°C. Then the hASC-ACPC mixtures were transplanted subcutaneously to the dorsal regions of nude mice \( n = 6 \) per group) for the analyses of heterotopic bone formation \( in vivo \) 8 weeks later. After being collected and fixed in 4% paraformaldehyde, the samples were photographed with soft X-ray. The radiograph was obtained by applying a Senograph 2000D molybdenum-rhodium twin target X-ray apparatus (GE, Fairfield, CT, USA). The radiation distance is 20 cm and the radiographing conditions were 22.0 kV, 35.0 mA. For histological evaluation, the specimens were decalcified in 10% ethylene diamine tetraacetic acid solution (pH 7.4) for 14 d, embedded into paraffin, then sliced into 5 μm-thick sections before the subsequent hematoxylin and eosin (HE) staining and Masson trichrome staining. The rabbit anti-OCN primary antibodies diluted to 1:100 (Servicebio, Wuhan, Hubei, China; GB11233) were used for immunohistochemical (IHC) staining.

**Statistical analysis**

Data and statistical analyses were conducted with SPSS Statistics 20.0 software (IBM, Armonk, NY, USA). All data were shown as mean ± standard deviation (SD) of three individual experiments. For the comparison of two or multiple groups, Student's t-test or one-way analysis of variance (ANOVA) combined with Tukey's test were applied, respectively. A two-tailed test with \( p \) value < .05 was indicated as statistically significant.

**Results**

**MiR-137 reversely regulates hASC differentiation along osteoblastic lineage in vitro**

Our previous study displayed an overall downward expression trend of miR-137 in hASCs during the osteoblastic induction and identified its negative role in this biological process [32]. Since lacking research on the osteogenic function of miR-137, firstly, we re-verified the reliability of our previous results. After transfecting hASCs with lentiviruses of NC, miR-137 overexpression, and miR-137 knockdown (Additional file 1: Fig. S1a), we evaluated the transfection rate was over 90% by computing the percentage of GFP-tagged cells (Additional file 1: Fig. S1b). Meanwhile, the transfection effects were quantitatively determined on 3 d, 7 d and 14 d by qRT-PCR analysis (Additional file 1: Fig. S1c).

ALP staining and activity assays displayed that miR-137 overexpression reduced ALP activity of hASCs under proliferation condition or osteogenic induction, but miR-137 knockdown resulted in adverse consequences (Fig. 1a, b). ARS staining and quantification were applied to test the calcium deposits of extracellular matrix. More mineralized nodules were presented in miR-137 knockdown group while less in
miR-137 overexpression group when both were compared with NC group (Fig. 1c, d). Besides, the characteristic genes expressed in different stages of osteogenesis, including RUNX2, ALP, and OCN, were examined by qRT-PCR and presented significant decreases in miR-137 overexpression group but dramatically increased in miR-137 knockdown group (Fig. 1e). According to these data, we substantiated that miR-137 inhibits in vitro osteoblastic activity of hASCs.

**MiR-137 reversely regulates hASC differentiation along osteoblastic lineage in vivo**

In order to validate in vivo osteogenic effects of miR-137, hASCs were transfected with NC, miR-137, and anti-miR-137 lentiviruses and separately mixed with ACPC, and then the compounds were subcutaneously implanted into the dorsum of nude mice (Fig. 2a). After eight weeks, the total volume and mean density of the harvested samples were assessed and manifested an apparent enhancement in miR-137 knockdown group but remarkable reduction in miR-137 overexpression group (Fig. 2b, c).

Histological analyses of bone formation were performed by staining of HE, Masson trichrome and IHC staining for OCN. HE staining showed more new bone formation in miR-137 knockdown group when comparing with NC group, which displayed only a very small amount of osteoid, but we could hardly observe any new bone or osteoid in miR-137 overexpression group. Similarly, thicker and more compact blue-green stained collagen fiber bundles were detected in miR-137 knockdown group than in another two groups, but overexpression of miR-137 led to the thinnest collagen deposition. Moreover, we found that dark-brown stained OCN granules were the most widespread in the cells of miR-137 knockdown group, fewer in NC group, and none could be discerned in miR-137 overexpression group (Fig. 2d). Consequently, in accordance to the results of in vitro experiments, miR-137 subdues the osteoblastic activity of hASCs in vivo.

**MiR-137 regulates NOTCH1-HES1 pathway by directly targeting NOTCH1**

To ascertain the influences of miR-137 on NOTCH1 pathway, we first examined the expression of NOTCH1 and its downstream signal HES1 with miR-137 overexpression or knockdown. When compared with NC group, the mRNA and protein levels of NOTCH1 showed obvious increase in miR-137 knockdown group while marked reduction in miR-137 overexpression group. Contrary to NOTCH1, the expression tendency of HES1 accorded with the changes of miR-137 (Fig. 3a–c). These findings suggested that NOTCH1 is negatively regulated while HES1 is positively regulated by miR-137.

To further identify whether miR-137 could directly bind to NOTCH1 in hASCs as it does in other cell lines [40–44], dual-luciferase reporter assays were carried out. The presumed targeting sites of miR-137 in the 3’ UTR of NOTCH1 were forecasted by two prediction softwares (TargetScan and RNA22). Then the luciferase reporter vectors carrying the 3’ UTR of NOTCH1-WT or NOTCH1-MT (Fig. 3d, e) were constructed and the relative luciferase activities were detected. MiR-137 mimics significantly repressed the luciferase activity in NOTCH1-WT group while had no significant influences in NOTCH1-MT group when both groups were compared with their respective NC groups (Fig. 3f). These results validated that miR-137 directly binds to the 3’ UTR of NOTCH1 and induces the expression of HES1 in hASCs.
**NOTCH1 knockdown impairs osteogenesis by inducing HES1 and LSD1 while inhibiting BMP2-SMAD4 pathway**

To determine the influences of NOTCH1 knockdown on the osteoblastic potential of hASCs, we applied ALP and ARS staining combined with quantitative analysis and found that NOTCH1 knockdown attenuated ALP activity and extracellular mineralization (Fig. 4a–d). As the downstream molecules of NOTCH1, HES1 and RUNX2 were further detected at mRNA and protein levels in hASCs transfected with NOTCH1 knockdown lentiviruses. Coincident with the impacts of miR-137 on NOTCH1-HES1 pathway, NOTCH1 knockdown induced the expression of HES1 while repressed RUNX2 (Fig. 4e–g). Our results indicated that NOTCH1 knockdown impedes the osteogenic potential of hASCs by the stimulation of HES1, corroborating the former conclusions that miR-137 inhibits osteogenesis by the downregulation of NOTCH1 and upregulation of HES1.

Since our previous study has demonstrated that miR-137 upregulated LSD1 while downregulated BMP2 and SMAD4 in hASCs [32], we further investigated the influences of NOTCH1 knockdown on LSD1 and BMP2-SMAD4 pathway. As predicted, both the mRNA and protein expression of LSD1 significantly increased after knocking down NOTCH1, whereas BMP2 and SMAD4 decreased apparently (Fig. 4h–j). Therefore, we deduced that the osteogenic inhibition of NOTCH1 knockdown is also dependent on the activation of LSD1 and suppression of BMP2-SMAD4 pathway. Collectively, NOTCH1 knockdown attenuates osteoblastic differentiation by inducing HES1 and LSD1 while inhibiting BMP2-SMAD4 pathway in hASCs.

**LSD1 knockdown regulates NOTCH1-HES1 pathway**

As above, we have affirmed that NOTCH1 acts as a negative regulator in LSD1 expression. But considering the complex interplay of signaling molecules, we tried to clarify whether LSD1 had feedback effects on NOTCH1-HES1 pathway. Notably, we found that LSD1 knockdown led to a higher level of NOTCH1 while lowered the expression of HES1 when compared with NC group (Fig. 5a–c), thus prompting a reciprocal negative relationship between NOTCH1 and LSD1.

**BMP2 knockdown inhibits NOTCH1 while induces LSD1**

To gain further insights into the relationships between NOTCH1, LSD1 and BMP2 signals, we then examined the expression of NOTCH1 and LSD1 at mRNA and protein levels after knocking down BMP2. Importantly, the expression of NOTCH1 dramatically decreased while LSD1 increased with BMP2 knockdown (Fig. 5d–f). Combining with the above results that NOTCH1 knockdown inhibited BMP2-SMAD4 pathway, we verified a positive feedback loop between NOTCH1 and BMP2. Furthermore, our previous study revealed that silencing of LSD1 promoted the osteoblastic potential of hASCs by stimulating BMP2-SMAD4 signaling pathway [32]. Here again, we observed upward tendencies in the expression of BMP2, SMAD4, RUNX2 and ALP with knockdown of LSD1 (Additional file 2: Fig. S2). Therefore, a negative interplay between LSD1 and BMP2 was also confirmed by us.
In conclusion, these data revealed that depending on the reciprocal negative regulation between NOTCH1 and LSD1, LSD1 and BMP2, as well as the synergistic function between NOTCH1 and BMP2, miR-137 negatively regulates osteogenesis of hASCs through the NOTCH1/LSD1/BMP2 co-regulatory signaling network (Fig. 6).

**Discussion**

Dysfunction of miR-137 has been implicated in several cancer types such as glioblastoma [19], melanoma [20], multiple myeloma [21], non-small cell lung cancer [22], and endometrial cancer [23]. In addition, miR-137 has been found to play an essential role in neural development and maturation, with several studies displaying an association with cell proliferation and neurogenic differentiation [24–31]. However, little is known concerning its functions and regulatory mechanisms on the osteoblastic differentiation, especially in mesenchymal stem cells. Silencing of miR-137-3p is found to facilitate the osteogenesis of bone marrow-derived mesenchymal stem cells by targeting RUNX2 [50]. Previously, we demonstrated that silencing of miR-137 promoted the osteoblastic activity in hASCs and revealed its modulation on the signaling network of LSD1/BMP2/SMAD4 as part of the mechanisms [32]. Interestingly, our former research confirmed a positive role of miR-137 in LSD1 expression, which was contrary to several studies reporting that miR-137 directly binds to LSD1 [23, 26, 51, 52]. The contradicted outcomes might be associated with the various biological features of different cell types, and we deduced that there probably exist intermediary regulators working between miR-137 and LSD1 during the osteogenesis of hASCs. Strikingly, this study identified that NOTCH1 was a direct target of miR-137 in hASCs and NOTCH1-HES1 pathway was engaged in the crosstalk between LSD1 and BMP2-SMAD4 pathway. In this way, NOTCH1 signal mediated the control of miR-137 on LSD1/BMP2/SMAD4 network. Moreover, the interrelations of the above signals were validated comprehensively and a NOTCH1/LSD1/BMP2 co-regulatory network was established, further elucidating the epigenetic mechanisms of miR-137 during the process of hASCs differentiating into osteoblastic lineage.

After reconfirming the inhibitory impacts of miR-137 on the osteoblastic activity of hASCs both *in vitro* and *in vivo*, we demonstrated that miR-137 negatively regulated the expression of NOTCH1 while positively regulated HES1. NOTCH signaling pathway influences tumorigenesis as well as embryonic development [53] because of its crucial role in cell fate determination, proliferation, differentiation, and apoptosis [54]. Though it is still debatable whether NOTCH signal plays a positive or negative role in osteogenesis [55], our data displayed impaired osteogenic capacity of hASCs after knocking down NOTCH1. More strikingly, NOTCH1 was validated as a direct target gene of miR-137 in hASCs, the same as in other cell lines [40–44]. HES1 is known as a potential downstream target of NOTCH1 in many studies, but it is not affected in NOTCH1 knockout mice while the expression of HES5, HES-related repressor protein (HERP)1, -2, and -3 are greatly diminished [56–58]. As a transcriptional regulator in the NOTCH signaling pathway, recombination signal binding protein (RBPJ) gene disruption in homozygous mice exhibits reduced HES5 expression, but not for HES1 [56]. Given the various effects on OCN, osteopontin and RUNX2 [37, 38], HES1 influences the osteogenesis inconsistently depending on the different cellular environments. This study showed upregulated HES1 with NOTCH1 knockdown,
indicating that NOTCH1 plays as a negative regulator in the expression of HES1. Collectively, we brought insight into how the NOTCH1-HES1 pathway was regulated by miR-137.

LSD1 has been linked to the repression of NOTCH1 pathway in various cell types [45, 59–63], though one study states that it functions as a corepressor when associated with RBPJ-repressor complex and as a NOTCH1 coactivator upon NOTCH activation [64]. Nevertheless, few studies have reported the interplay between NOTCH1 and LSD1 during the osteogenesis of hASCs and whether this interaction contributes to the osteogenic regulation of miR-137 is still unknown. Coincident with the influences of miR-137 on NOTCH1 and LSD1, we uncovered a negative interaction between NOTCH1 and LSD1 with separate knockdown of them. More intriguingly, despite inducing NOTCH1, LSD1 knockdown reduced the expression of HES1. Thus, the opposite expression trends of NOTCH1 and HES1 caused by LSD1 knockdown might reinforce the downregulation of HES1 by NOTCH1 alone. These results verified the crosstalk between NOTCH1-HES1 pathway and LSD1, through which miR-137 regulates the osteogenic differentiation of hASCs.

BMP signal is a canonical pathway in skeleton and BMP2-SMAD4 pathway has been shown to participate in the osteogenic regulation of miR-137 by us [32]. After knocking down NOTCH1 and BMP2 individually, we observed suppressed expression of NOTCH1, BMP2 and SMAD4 simultaneously, indicating a positive interrelationship between NOTCH1 and BMP2-SMAD4 pathway. Considering our previous results that LSD1 knockdown activated the BMP2-SMAD4 pathway [32], in turn, we investigated the impacts of BMP2 on LSD1. As expected, LSD1 was significantly upregulated with BMP2 knockdown. Thus, these findings suggested a negative feedback loop between LSD1 and BMP2-SMAD4 pathway.

Conclusions

In summary, our study provided a relatively comprehensive rationale for the negative control of miR-137 during the hASC differentiation towards osteoblastic lineage and established a co-regulatory network of NOTCH1/LSD1/BMP2 to elucidate the underlying mechanisms, which is of substantial importance for potential targeted therapy of bone-related diseases.

Figures
Figure 1

MiR-137 reversely regulates hASC differentiation along osteoblastic lineage in vitro. a, b ALP staining (a) and quantification (b) of transfected hASCs after a 7-day culture in PM or OM (scale bar = 100 μm). c, d ARS staining (c) and quantification (d) of transfected hASCs after a 14-day culture in PM or OM. e Relative expression analyses of RUNX2, ALP, and OCN by qRT-PCR in transfected hASCs on 3 d, 7 d, and
Figure 2

MiR-137 reversely regulates hASC differentiation along osteoblastic lineage in vivo. a Schema of the experimental design for in vivo study. n = 6 per group. b Representative soft X-ray photographs of the specimens which were subcutaneously harvested from the dorsal pockets of nude mice 8 weeks later. c
Mean density analyses by the application of ImageJ software. Data are shown as mean ± SD of six independent experiments. *p < 0.05 versus NC group. Heterotopic bone formation was evaluated by histological stainings: HE, Masson trichrome staining (scale bar = 50 μm), and IHC staining of OCN (scale bar = 20 μm). Typical dark brown particles indicating OCN depositions in hASCs were marked with black arrows.
MiR-137 regulates NOTCH1-HES1 pathway by directly targeting NOTCH1. a Relative expression analyses of NOTCH1 and HES1 by qRT-PCR in transfected hASCs on 3 d, 7 d and 14 d. b, c Western blotting (b) and band intensity analyses (c) of NOTCH1 and HES1 in transfected hASCs. d The structure diagram of a luciferase reporter vector containing the 3' UTR of NOTCH1-WT or NOTCH1-MT. e Softwares (TargetScan and RNA22) predicted the binding sites of miR-137 located in the 3' UTR of NOTCH1-WT (underlined parts indicated the mutated bases in NOTCH1-MT). f Luciferase activity analyses of the NOTCH1-WT and NOTCH1-MT. Data are shown as mean ± SD of three independent experiments performed in triplicate. *p < 0.05 versus NC group.
Figure 4

NOTCH1 knockdown impairs osteogenesis by inducing HES1 and LSD1 while inhibiting BMP2-SMAD4 pathway. a, b ALP staining (a) and quantification (b) of transfected hASCs after a 7-day culture in PM or OM (scale bar = 100 μm). c, d ARS staining (c) and quantification (d) of transfected hASCs after a 14-day culture in PM or OM. e Relative expression analyses of NOTCH1, HES1 and RUNX2 by qRT-PCR in transfected hASCs on 3 d, 7 d and 14 d. f, g Western blotting (f) and band intensity analyses (g) of
NOTCH1, HES1 and RUNX2 in transfected hASCs. h Relative expression analyses of LSD1, BMP2 and SMAD4 by qRT-PCR in transfected hASCs on 3 d, 7 d and 14 d. i, j Western blotting (i) and band intensity analyses (j) of LSD1, BMP2 and SMAD4 in transfected hASCs. Data are shown as mean ± SD of three independent experiments performed in triplicate. *p < 0.05 versus NC group

Figure 5
LSD1 or BMP2 knockdown influences NOTCH1/LSD1/BMP2 signaling network. a Relative expression analyses of LSD1, NOTCH1 and HES1 by qRT-PCR in transfected hASCs on 3 d, 7 d and 14 d. b, c Western blotting (b) and band intensity analyses (c) of LSD1, NOTCH1 and HES1 in transfected hASCs. d Relative expression analyses of BMP2, NOTCH1 and LSD1 by qRT-PCR in transfected hASCs on 3 d, 7 d and 14 d. e, f Western blotting (e) and band intensity analyses (f) of BMP2, NOTCH1 and LSD1 in transfected hASCs. Data are shown as mean ± SD of three independent experiments performed in triplicate. *p < 0.05 versus NC group

Figure 6

A diagrammatic view of NOTCH1/LSD1/BMP2 network in miR-137-mediated differentiation of hASCs towards osteoblastic lineage. In this complex network model, miR-137 controls NOTCH1-HES1, LSD1, and BMP2-SMAD4 pathways simultaneously. Depending on the positive feedback loop between NOTCH1 and BMP2, as well as the negative reciprocal relationship between LSD1 and NOTCH1 or BMP2, the impacts of miR-137 on the above three signaling pathways are strengthened and the NOTCH1/LSD1/BMP2
network regulates the osteogenesis of hASCs coordinately (red lines represent inhibition and green lines represent promotion)
