Rank two non-commutative Laurent phenomenon and pseudo-positivity

Dylan C. Rupel

Abstract We study polynomial generalizations of the Kontsevich automorphisms acting on the skew-field of formal rational expressions in two non-commuting variables. Our main result is the Laurentness and pseudo-positivity of iterations of these automorphisms. The resulting expressions are described combinatorially using a generalization (studied in [10]) of the combinatorics of compatible pairs in a maximal Dyck path developed by Lee, Li, and Zelevinsky in [8].

By specializing to quasi-commuting variables we obtain pseudo-positive expressions for rank 2 quantum generalized cluster variables. In the case that all internal exchange coefficients are zero, this quantum specialization provides a positive combinatorial construction of counting polynomials for Grassmannians of submodules in exceptional representations of valued quivers with two vertices.

Let \( k \) be any field of characteristic zero. Write \( K = k(X,Y) \) for the skew-field of rational functions in non-commuting variables \( X \) and \( Y \). Intuitively, writing \( \pi : k(X,Y) \to k(x,y) \) for the commutative specialization, we may formally invert any element \( W \in K \) for which \( \pi(W) \neq 0 \); this idea has been made precise in [16] by considering iterated localizations of the free algebra \( k(X,Y) \).

For any nonzero polynomial \( P \in k[z] \), consider the following \( k \)-linear automorphism of \( K \):

\[
F_P : \begin{cases} 
X \mapsto XYX^{-1} \\
Y \mapsto P(Y)X^{-1}.
\end{cases}
\]

We remark for later use that the element \( Q := XYX^{-1}Y^{-1} \) is fixed by \( F_P \) for any nonzero polynomial \( P \). Also note that \( F_P^{-1} \) is given by \( X \mapsto P(X)Y^{-1} \) and \( Y \mapsto YXY^{-1} \).

Fix nonzero monic polynomials \( P_1, P_2 \in k[z] \) such that \( P_1(0) = 1 = P_2(0) \), say

\[
P_i(z) = p_{i,0} + p_{i,1}z + \cdots + p_{i,d_i-1}z^{d_i-1} + p_{i,d_i}z^{d_i}
\]

with \( p_{i,0} = p_{i,d_i} = 1 \) for \( i = 1, 2 \). Set \( \mathbb{A}_+ = \mathbb{Z}_{\geq 0}[p_{1,i}, p_{2,j} : 0 \leq i \leq d_1, 0 \leq j \leq d_2] \) and call this the pseudo-positive semiring associated to \( P_1 \) and \( P_2 \).

We will write \( \bar{P}_1(z) := z^{d_1}P_1(z^{-1}) \) and \( \bar{P}_2(z) := z^{d_2}P_2(z^{-1}) \) for the polynomials obtained from \( P_1 \) and \( P_2 \) by reversing the order of the coefficients. Note that these are...
again polynomials of the same form. For notational convenience, for \( k \in \mathbb{Z} \) we define

\[
P_k = p_{k,0} + p_{k,1}z + \cdots + p_{k,d_k-1}z^{d_k-1} + p_{k,d_k}z^{d_k} = \begin{cases} P_2 & \text{if } k \equiv 0 \mod 4; \\ P_1 & \text{if } k \equiv 1 \mod 4; \\ P_2 & \text{if } k \equiv 2 \mod 4; \\ P_1 & \text{if } k \equiv 3 \mod 4. \end{cases}
\]

Here we use the notation \( d_k := d_1 \) if \( k \) is odd and \( d_k := d_2 \) if \( k \) is even.

**Main Theorem.** For any \( m \geq 0 \), the elements \( X_m, Y_m \in \mathbb{K} \) given by

\[
X_m := F_{P_1}F_{P_2}\cdots F_{P_m}(X) \quad \text{and} \quad Y_m := F_{P_1}F_{P_2}\cdots F_{P_m}(Y)
\]

are contained in the semiring \( \mathbb{A}_+(X^{\pm 1}, Y^{\pm 1}) \subset \mathbb{K} \) of pseudo-positive non-commutative Laurent polynomials.

**Remark.** When \( P_1 \) and \( P_2 \) are monic and of the same degree but \( P_1(0) = P_2(0) \neq 1 \), this result also holds and can be deduced from the Main Theorem by passing to an appropriate algebraic extension of \( \mathbb{K} \), then rescaling all variables. The same is true when the coefficients \( p_{1,0}, p_{1,d_1}, p_{2,0}, p_{2,d_2} \neq 0 \) are arbitrary but satisfy a balancing condition which we leave as an exercise for the reader to work out. In the absence of such a balancing condition the definitions of the polynomials \( P_k \) should be adjusted according to the exchange polynomial mutation rules developed by Chekhov and Shapiro [4]. Also, since \( F_P(X) = QY \) for any polynomial \( P \), we have \( X_{m+1} = QY_m \) for \( m \geq 0 \); in particular, the claim for the \( X_m \) follows from the claim for the \( Y_m \).

**Remark.** If \( d_1d_2 \leq 3 \), the Main Theorem can be observed quite explicitly by computing \( X_1, X_2, \ldots, X_m \) by hand for

\[
m = \begin{cases} 4 & \text{if } d_1d_2 = 0; \\ 5 & \text{if } d_1d_2 = 1; \\ 6 & \text{if } d_1d_2 = 2; \\ 8 & \text{if } d_1d_2 = 3; \end{cases}
\]

and observing in each case that these are given by pseudo-positive non-commutative Laurent polynomials with \( X_m = QXQ^{-1} \). The combinatorics below can be adapted to these cases, however in everything that follows we assume \( d_1d_2 \geq 4 \) as such cases may be treated more uniformly.

For the following example, observe that the \( Y_m \) for \( m \geq 2 \) may alternatively be computed via the following non-commutative analogue of generalized cluster exchange relations:

\[
Y_m QY_{m-2} = 1 + p_{m,1}Y_{m-1} + \cdots + p_{m,d_m-1}Y_{m-1}^{d_m-1} + Y_{m-1}^{d_m}.
\]

**Example.** Let \( P_1 = 1 + p_{1,1}z + p_{1,2}z^2 + z^3 \) and \( P_2 = 1 + p_{2,1}z + z^2 \). Then the first few non-commutative generalized cluster variables \( Y_m \) are given by:

\[
Y_1 = (1 + p_{1,1}Y + p_{1,2}Y^2 + Y^3)X^{-1}, \quad Y_2 = (1 + p_{2,1}Y_1 + Y_2)Y^{-1}Q^{-1}, \quad Y_3 = (1 + p_{1,2}Y_2 + p_{1,1}Y_3^2)Y_1^{-1}Q^{-1}.
\]

While \( Y_2 \) is manifestly an element of \( \mathbb{A}_+(X^{\pm 1}, Y^{\pm 1}) \), a highly nontrivial cancellation must occur in the expansion of \( Y_3 \) in order for it to be a pseudo-positive non-commutative Laurent polynomial. Such cancellations indeed occur and we obtain the
The automorphisms $F_{P_k}$ are generalizations of automorphisms of $\mathbb{K}$ introduced by Kontsevich [7] which are recovered in the binomial case when $p_{1,i} = 0 = p_{2,j}$ for $1 \leq i \leq d_1 - 1$ and $1 \leq j \leq d_2 - 1$. In this binomial case, Kontsevich conjectured the Laurentness and positivity of the non-commutative cluster variables $X_m$ and $Y_m$. This terminology is justified by specializing to commutative variables through which we recover the initial cluster mutations in the rank two cluster algebra [6] associated to the exchange matrix \[
\begin{pmatrix}
0 & d_2 \\
-d_1 & 0
\end{pmatrix}
\] after composing with the transposition of initial cluster variables. In the binomial case, Laurentness was established by Usnich [15] when $d_1 = d_2 = 2$, and by Berenstein and Retakh [2] for arbitrary polynomial degrees. Positivity in the binomial case was proven by Di Francesco and Kedem [5] when $d_1d_2 = 4$, by Lee and Schiffler [9] for $d_1 = d_2$, and by the author [12] for arbitrary polynomial degrees.

The Laurentness of $X_m$ and $Y_m$ was established by Usnich [14] in the special case where $F_k = P_k$ for all $k \in \mathbb{Z}$. We will prove the Main Theorem by providing a combinatorial construction of the elements $Y_m$, called non-commutative generalized cluster variables. This combinatorics was studied by the author [10] to construct greedy bases for (commutative) rank two generalized cluster algebras by building upon the notion of compatible pairs in a maximal Dyck path developed by Lee, Li, and Zelevinsky [8] for constructing greedy bases of rank two cluster algebras.

For an $a = (a_1, a_2) \in \mathbb{Z}_{\geq 0}^2$, let $D := D_a$ denote the lattice path in the rectangle $[0, a_1] \times [0, a_2]$ which begins at $(0, 0)$ takes unit length East and North steps to end at $(a_1, a_2)$ and is maximal among all such Dyck paths that never pass above the main diagonal of the rectangle $[0, a_1] \times [0, a_2]$. In other words, no lattice point of $D$ lies strictly above the main diagonal and any lattice point which lies strictly above $D$ also lies strictly above the main diagonal. Label the edges of $D$ as $E = \{1, \ldots, a_1 + a_2\}$, where this bijection of ordered sets respects the natural order on edges from $(0, 0)$ to $(a_1, a_2)$. There is a partition $E = H \cup V$, where $H$ (resp. $V$) denotes the set of horizontal (resp. vertical) edges of $D$.

For edges $e, e' \in E$, we write $ee'$ for the subpath of $D$ beginning with $e$ traveling North-East and ending with $e'$. By convention, this path will be empty if $e$ is to the North-East of $e'$, while the path $ee$ contains the single edge $e$. Let $\bar{e}e'$ (resp. $ee''$) denote the path obtained from $ee'$ by removing the edge $e$ (resp. $e'$). Write $(ee')_{H}$ (resp. $(ee')_{V}$) for the set of horizontal (resp. vertical) edges in the path $ee'$. We abbreviate $|ee'|_H := |(ee')_H|$ and $|ee'|_V := |(ee')_V|$.

Remark 1.1. In [8] and [10], the definition for subpaths $ee'$ of $D$ includes a “wrap-around” condition whereby $ee'$ is non-empty for $e' < e$, however following [10, Remark 2.21] such a condition will not be necessary in our situation and all relevant results quoted from [10] will be modified accordingly.

Definition 1.2. A grading $\omega : E \rightarrow \mathbb{Z}_{\geq 0}$ (on the edges) of $D$ is called compatible if: for every $h \in H$ and $v \in V$, there exists an edge $e$ along the path $hv$ so that at least
one of the following holds:

(HGC) \[ e \neq v \quad \text{and} \quad |he|_V = \sum_{h' \in \{he\} \cap H} \omega(h'); \]

(VGC) \[ e \neq h \quad \text{and} \quad |ev|_H = \sum_{v' \in \{ev\} \cap V} \omega(v'). \]

Recall that \( d_1, d_2 \in \mathbb{Z}_{\geq 0} \) denote the degrees of the exchange polynomials \( P_1 \) and \( P_2 \) respectively. We say that a grading \( \omega \) of \( D \) is \((d_1, d_2)\)-bounded if \( \omega(h) \leq d_1 \) for all \( h \in H \) and \( \omega(v) \leq d_2 \) for all \( v \in V \). For the remainder of the paper we will restrict to such bounded gradings \( \omega \), though we continue to write \( \omega : E \to \mathbb{Z}_{\geq 0} \) throughout.

This notion of compatible gradings was introduced in [10] building upon the notion of compatible subsets of \( E \) developed in [8] which can be recovered when \( \omega(h) \in \{0, d_1\} \) for \( h \in H \) and \( \omega(v) \in \{0, d_2\} \) for \( v \in V \).

For a \((d_1, d_2)\)-bounded grading \( \omega \), we associate the non-commutative monomial \( \text{wt}_{\omega}(e) \) to each edge \( e \in E \) as follows:

\[
\text{wt}_{\omega}(e) = \begin{cases} 
  p_{1, \omega(e)} Y^{\omega(e)} X^{-1} & \text{if } e \in H; \\
  p_{2, d_2 - \omega(e)} Y^{\omega(e) + 1} X^{-1} & \text{if } e \in V.
\end{cases}
\]

Thus we may associate a non-commutative Laurent monomial to each \((d_1, d_2)\)-bounded grading \( \omega \) by taking the product of the associated non-commutative weights in the natural order along the path \( D \):

\[
Y_D(\omega) := \text{wt}_{\omega}(1) \cdot \text{wt}_{\omega}(2) \cdots \text{wt}_{\omega}(a_1 + a_2).
\]

Define \( Y_D := \sum Y_D(\omega) \), where the sum ranges over all \((d_1, d_2)\)-bounded compatible gradings \( \omega \) of \( \hat{D} \).

We will mainly be interested in the maximal Dyck paths \( D_m := D_{a_m} \) for integer vectors \( a_m \in \mathbb{Z}^2, m \geq 1 \), defined recursively by

\[
a_0 = (0, -1), \ a_1 = (1, 0), \ \text{a}_{m-1} + \text{a}_{m+1} = \begin{cases} 
  d_2 \text{a}_m & \text{if } m \text{ is odd}; \\
  d_1 \text{a}_m & \text{if } m \text{ is even}.
\end{cases}
\]

These vectors are precisely the almost positive roots in the root system associated to the Cartan matrix \( \begin{pmatrix} 2 & -d_2 \\
-d_1 & 2 \end{pmatrix} \) which describe the denominator vectors of cluster variables. The Main Theorem is an immediate consequence of the following combinatorial construction of the non-commutative generalized cluster variables \( Y_m \).

**Theorem 1.3.** For \( m \geq 1 \), we have \( Y_{D_m} = Y_m \).

**Example 1.4.** We continue the example from above with \( P_1 = 1 + p_{1,1} z + p_{1,2} z^2 + z^3 \) and \( P_2 = 1 + p_{2,1} z + z^2 \).

For \( m = 1 \), we get \( a_1 = (1, 0) \) so that \( D_1 = \begin{tikzpicture}[baseline=-0.5ex]
\draw (0,0) -- (1,0);
\draw (1,0) -- (1,1);
\draw (1,1) -- (2,1);
\end{tikzpicture} \). This maximal Dyck path consists of a single horizontal edge which may be assigned any of the weights 0, 1, 2, 3, a situation which we denote by the dashed edge \( \begin{tikzpicture}[baseline=-0.5ex]
\draw[very thick,dash pattern=on 2pt off 4pt] (0,0) -- (1,0);
\end{tikzpicture} \). Summing the monomial contributions coming from (4) for each choice of weight, we get

\[
Y_{D_1} = X^{-1} + p_{1,1} Y X^{-1} + p_{1,2} Y^2 X^{-1} + Y^3 X^{-1} = Y_1
\]

and this same equality holds for any dashed edge below.

For \( m = 2 \), we get \( a_2 = (2, 1) \) so that \( D_2 = \begin{tikzpicture}[baseline=-0.5ex]
\draw (0,0) -- (1,0);
\draw (1,0) -- (1,1);
\draw (1,1) -- (1,2);
\draw (1,2) -- (2,2);
\end{tikzpicture} \). In this case, the compatible weightings of the edges in \( D_2 \) are given by

\[
\begin{tikzpicture}[baseline=-0.5ex]
\draw (0,0) -- (1,0);
\draw (1,0) -- (1,1);
\draw (1,1) -- (1,2);
\draw (1,2) -- (2,2);
\end{tikzpicture} \begin{tikzpicture}[baseline=-0.5ex]
\draw (0,0) -- (1,0);
\draw (1,0) -- (1,1);
\draw (1,1) -- (1,2);
\draw (1,2) -- (2,2);
\end{tikzpicture} \begin{tikzpicture}[baseline=-0.5ex]
\draw (0,0) -- (1,0);
\draw (1,0) -- (1,1);
\draw (1,1) -- (1,2);
\draw (1,2) -- (2,2);
\end{tikzpicture}
\]
where we again use a dashed line to indicate that a horizontal edge may be assigned any of the weights 0, 1, 2, 3 without affecting compatibility. Summing the monomial contributions coming from (4) for each choice of weight, we get

\[ Y_{D_3} = Y_1^2 X Y^{-1} X^{-1} + Y_1 X^{-1} p_{2,1} X^2 Y^{-1} X^{-1} + X^{-1} X^3 Y^{-1} X^{-1} = Y_2. \]

For \( m = 3 \), we get \( a_3 = (5, 3) \) so that \( D_3 = \). In this case, the compatible weightings of the edges in \( D_3 \) are given by

\[\begin{array}{cccc}
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
& & & \\
\end{array}\]

To describe the non-commutative generalized cluster variables \( Y_1, Y_2, Y_3 \) above as pseudo-positive non-commutative Laurent polynomials we consider the following roots and corresponding maximal Dyck paths:

\[ a_1 = (1, 0) \quad D_1 = \]
\[ a_2 = (2, 1) \quad D_2 = \]
\[ a_3 = (5, 3) \quad D_3 = \]

Our proof of Theorem 1.3 requires a careful understanding of the recursive structure of the maximal Dyck paths \( D_m \) which we will establish in the next section. In Section 3, we further develop the combinatorics of compatible gradings of \( D_m \) introduced in [10]. The main aim there is to understand gradings which behave nicely with respect to the recursive structure developed in Section 2. These results produce nicely factorizable summands of \( Y_{D_m} \), facilitating an inductive proof of Theorem 1.3. Section 4 puts these combinatorial results together to establish Theorem 1.3. We finish with Section 5 discussing the specialization from non-commutative variables to quasi-commuting variables. A main goal of this section is proving Corollary 5.7 which gives a positive combinatorial construction of counting polynomials for Grassmannians of subrepresentations in rigid indecomposable valued quiver representations.

**Notation.** We adopt the following notational conventions throughout the paper.

- For integers \( a < b \), set \([a, b] = \{a, a + 1, \ldots, b\}\).
- Given any quantity \( \alpha \) defined using the tuple \((d_1, d_2)\) or the pair of polynomials \((P_1, P_2)\), let \( \alpha' \) denote the same quantity defined using the tuple \((d'_1, d'_2) = (d_0, d_1)\) or the polynomials \((P'_1, P'_2) = (P_0, P_1)\). In particular, \( p'_{1,j} = p_{2,d_2-j} \) and \( p'_{2,j} = p_{1,j} \) when equation (4) is applied to a \((d'_1, d'_2)\)-bounded grading \( \omega' \) on \( D_{m'} \).
- Equations that will be referenced globally will be assigned numbers, those that are referenced only locally (i.e. within a single proof) will be assigned symbols (e.g. \( \dagger \) or \( \ddagger \)). In particular, symbols labeling equations will be reused but this should not lead to any confusion.
2. Maximal Dyck Paths

In this section we study the recursive structure present in the maximal Dyck paths $D_m$. To accomplish this, we note that the vectors $a_m$ can be written more explicitly in terms of two-parameter Chebyshev polynomials $u_{m,k}$ ($m,k \in \mathbb{Z}$) defined recursively by:

$$u_{0,k} = 0, \quad u_{1,k} = 1, \quad u_{m+1,k+1} = d_k u_{m,k} - u_{m-1,k-1},$$

where $d_k$ denotes the degree of the polynomial $P_k$ in equation (1). Then, for $m \geq 1$, we have $a_m = (u_{m,1}, u_{m-1,2})$. Write $a'_m = (u'_{m,1}, u'_{m-1,2}) = (u_{m,2}, u_{m-1,1})$ and set $D'_m = D_{a'_m}$ for $m \geq 1$.

Remark 2.1. To see the equivalence with equation (6), one must use the identities $u_{m,k} = u_{m,k+1}$ for $m$ odd and $d_k u_{m,k} = d_k u_{m,k+1}$ for $m$ even.

We record the next simple observation for future use.

Lemma 2.2. For positive integers $d_1, d_2$ and any integers $m, k$, we have $u_{m,k+1} u_{m-2,k} < u_{m-1,k+1} u_{m-1,k}$.

Proof. We work by induction on $m$, the case $m = 2$ is the trivial inequality $0 < 1$. For $m \geq 3$, we have

$$u_{m,k+1} u_{m-2,k} = d_k u_{m-1,k} u_{m-2,k} - u_{m-2,k-1} u_{m-2,k} < d_k u_{m-1,k} u_{m-2,k} - u_{m-3,k-1} u_{m-1,k} = u_{m-1,k+1} u_{m-1,k},$$

where the inequality uses induction. The case $m \leq 1$ can be handled similarly. □

In order to establish a recursive structure for $D_m$ we will show that the maximal Dyck paths $D_m$ and $D'_m$ are intimately related.

Lemma 2.3. For $m \geq 1$, the following hold.

(a) The maximal Dyck path $D'_{m+1}$ can be obtained from $D_m$ via replacing each horizontal edge, together with the $\ell$ vertical edges which immediately follow it, by $d_1 - \ell$ horizontal edges followed by a vertical edge.

(b) The maximal Dyck path $D_{m+1}$ can be obtained from $D'_m$ via replacing each horizontal edge, together with the $\ell$ vertical edges which immediately follow it, by $d_2 - \ell$ horizontal edges followed by a vertical edge.

Proof. We prove (a) as (b) will immediately follow by interchanging the roles of $d_1$ and $d_2$. Let $D'$ denote the lattice path obtained from $D_m$ as in (a). It follows from the definition that $D'$ will contain $d_1 u_{m,1} - u_{m-1,2} = u_{m+1,2}$ horizontal edges and $u_{m,1}$ vertical edges. We need to show that $D'$ does not cross above the main diagonal and that it is maximal with this property.

Write $v'_1, \ldots, v'_{u_{m,1}}$ for the vertical edges of $D'$ and for $1 \leq r \leq u_{m,1}$ suppose $v'_r$ is immediately preceded by exactly $\ell_r$ horizontal edges of the same height. Suppose there exists $t$ so that $v'_t$ passes above the main diagonal, this is equivalent to the inequality $\sum_{r=1}^t \ell_r > \frac{u_{m+1,2}}{u_{m,1}}$. Using the equality $u_{m+1,2} = d_1 u_{m,1} - u_{m-1,2}$, this may be rewritten as

$$d_1 t - \sum_{r=1}^t \ell_r > \frac{u_{m+1,2}}{u_{m,1}}.$$

□
But by construction of $D'$, we see that $d_1 - \ell_r$ is the number of vertical edges immediately following the $r$-th horizontal edge of $D_m$. Thus, by rewriting the numerator as $d_1 t - \sum_{r=1}^t \ell_r = \sum_{r=1}^t (d_1 - \ell_r)$ in the inequality $(\ddagger)$, we see that the subpath of $D_m$ containing the first $t$ horizontal edges and the vertical edges immediately following these horizontal edges will cross above the main diagonal of the rectangle $[0, u_{m,1}] \times [0, u_{m-1,2}]$, a contradiction. Thus $D'$ is a Dyck path, i.e. it does not pass above the main diagonal.

To see that $D'$ is maximal, suppose there exists a lattice point $(s, t)$ strictly above $D'$ which does not lie above the main diagonal. Without loss of generality, we may take $s = \sum_{r=1}^t \ell_r - 1$ and get the inequality $\frac{d_1 t - \sum_{r=1}^t \ell_r + 1}{t} \leq \frac{u_{m-1,2}}{u_{m,1}}$. Using the equality $u_{m+1,2} = d_1 u_{m,1} - u_{m-1,2}$, this may be rewritten as

$$(\ddagger)$$

Now considering the same initial segment of $D_m$ as above, we see that the point $(t, d_1 t - \sum_{r=1}^t \ell_r + 1)$ lies strictly above $D_m$, but the inequality $(\ddagger)$ implies this point does not lie above the main diagonal of the rectangle $[0, u_{m,1}] \times [0, u_{m-1,2}]$, contradicting the maximality of $D_m$. Thus we may conclude that $D' = D'_{m+1}$ is the maximal Dyck path in the rectangle $[0, u_{m+1,2}] \times [0, u_{m,1}]$.

With this we obtain the recursive structure of $D_m$. In what follows we always assume $d_1 d_2 \geq 4$ and take $\delta_m = \begin{cases} 1 & \text{if } d_{m-1} = 1 \text{ and } m \neq 3; \\ 0 & \text{if } d_{m-1} \neq 1 \text{ or } m = 3. \end{cases}$

**Corollary 2.4.** The maximal Dyck paths $D_m$, $m \geq 1$, admit the following recursive structure:

(a) $D_1$ consists of a single horizontal edge;
(b) $D_2$ consists of $d_2$ horizontal edges followed by a single vertical edge;
(c) for $m \geq 3$, the Dyck path $D_m$ can be constructed by concatenating $d_m - 1 - \delta_m$ copies of $D_{m-1}$ followed by a copy of $D_{m-1}$ with its first $d_m - 2 - \delta_m$ removed.

For the remainder of the paper we will understand the notation $D_{m-1} \setminus D_{m-1 - \delta_m}$ to mean the terminal subpath of $D_{m-1}$ obtained by removing its first copy of $D_{m-2 - \delta_m}$ as in Corollary 2.4.

**Remark 2.5.** The roles of $d_1$ and $d_2$ must be interchanged when applying Corollary 2.4 to $D'_m$.

**Proof.** Parts (a) and (b) are immediate from the definitions of $D_1$ and $D_2$. Part (c) with $m = 3$ follows from Lemma 2.3 and part (b) since $D'_2$ consists of $d_1$ horizontal edges followed by a vertical edge.

We establish part (c) by induction on $m \geq 4$. Notice that by Remark 2.5 the claimed recursive structures of $D_m$ and $D'_m$ are the same for $m \geq 5$, thus we obtain the result for $D_m$ if we know the result for $D'_{m-1}$ by applying the construction from Lemma 2.3. Hence it suffices to establish the claimed recursive structure for $D_4$.

If $d_3 \neq 1$, then $\delta_3 = 0$ and the structure of $D_4$ is immediately deduced from Lemma 2.3 and part (c) for $D'_3$. If $d_3 = 1$, then $D'_3$ consists of a single horizontal edge followed by a single vertical edge and $D'_3$ consists of $d_2 - 1 = d_4 - 1$ copies of $D'_2$ followed by a vertical edge. Applying Lemma 2.3 to $D'_3$ shows that $D_4$ consists of
$d_4 - 2$ copies of $D_3$ followed by a copy of $D_3$ with its first horizontal edge (i.e. its first $D_1$) removed. This establishes part (c) for $D_4$ and completes the proof. \hfill $\square$

**Corollary 2.6.** For $m \geq 2$, if the last edge of $D_m$ is omitted, the resulting lattice path identifies with an initial subpath of the maximal Dyck path $C_m$ obtained by concatenating $d_m$ copies of $D_{m-1}$.

**Proof.** We work by induction on $m$, the case $m = 2$ following immediately from Corollary 2.4(b).

Assume $m \geq 3$. By part (c) of Corollary 2.4, in comparing $D_m$ to $C_m$ the first $d_m - 1 - \delta_m$ copies of $D_{m-1}$ inside $D_m$ may be ignored and the problem reduces to comparing the final $D_{m-1} \setminus D_{m-2-\delta_m}$ subpath of $D_m$ with the maximal Dyck path $D_{m-1}$. For $m = 3$, removing the final edge of $D_{m-1} \setminus D_{m-2-\delta_m}$ produces $d_2 - 1$ consecutive horizontal edges which clearly identifies with an initial subpath of $D_{m-1}$.

Assume $m \geq 4$. There are two cases to consider.

- If $d_{m-1} \neq 1$, $D_{m-1}$ consists of $d_{m-1} - 1 - \delta_{m-1}$ copies of $D_{m-2}$ followed by a copy of $D_{m-2} \setminus D_{m-3-\delta_{m-1}}$. It follows that comparing $D_{m-1} \setminus D_{m-2}$ with $D_{m-1}$ reduces to comparing $D_{m-2} \setminus D_{m-3-\delta_{m-1}}$ with $D_{m-2}$. By induction, we know that we obtain an initial subpath of $D_{m-2}$ by removing the last edge of $D_{m-2} \setminus D_{m-3-\delta_{m-1}}$.

- When $d_{m-1} = 1$, the maximal Dyck path $D_{m-1}$ is just $D_{m-2} \setminus D_{m-3}$. But $D_{m-2}$ consists of $d_m - 2$ copies of $D_{m-3}$ followed by a copy of $D_{m-3} \setminus D_{m-5}$ and so $D_{m-1}$ consists of $d_m - 3$ copies of $D_{m-3}$ followed by a copy of $D_{m-3} \setminus D_{m-5}$. Hence comparing $D_{m-1} \setminus D_{m-3}$ with $D_{m-1}$ reduces to comparing $D_{m-3} \setminus D_{m-5}$ with $D_{m-3}$, but by induction we know that removing the last edge of $D_{m-3} \setminus D_{m-5}$ produces an initial subpath of $D_{m-3}$.

The two items above show that we get an initial subpath of $D_{m-1}$ by removing the last edge of $D_{m-1} \setminus D_{m-2-\delta_m}$ and thus removing the last edge of $D_m$ produces an initial subpath of $C_m$. \hfill $\square$

Let $E_m$ denote the edges of $D_m$, where $E_m = H_m \sqcup V_m$ for horizontal edges $H_m = \{h_1, \ldots, h_{u_m}\}$ and vertical edges $V_m = \{v_1, \ldots, v_{u_{m-1}}\}$, both labeled in the natural order along $D_m$. We may describe the structure of $D_m$ as follows.

**Lemma 2.7** ([10, Lemma 3.2]). For $m \geq 2$, the following hold.

(a) There are exactly $ht(h_i) := \lfloor (i - 1)u_{m-1,2}/u_{m,1} \rfloor$ vertical edges of $D_m$ preceding the horizontal edge $h_i$, call this number the height of $h_i$;

(b) There are exactly $dp(v_i) := \lceil tu_{m,1}/u_{m-1,2} \rceil$ horizontal edges of $D_m$ preceding the vertical edge $v_i$, call this number the depth of $v_i$.

In the natural labeling of edges, Lemma 2.7 gives $h_i = i + \lfloor (i - 1)u_{m-1,2}/u_{m,1} \rfloor$ for $1 \leq i \leq u_{m,1}$, $m \geq 1$ and $v_t = t + \lceil tu_{m,1}/u_{m-1,2} \rceil$ for $1 \leq t \leq u_{m-1,2}$, $m \geq 2$.

In particular, we see that $u_{m-1,2} < u_{m,1}$ implies $D_m$ contains no consecutive vertical edges, while $u_{m,1} < u_{m-1,2}$ implies $D_m$ contains no consecutive horizontal edges.

For the next result, recall that we work under the assumption $d_1d_2 \geq 4$.

**Corollary 2.8.** For $m \geq 2$ the following hold.

(a) $D_m$ contains at most $1 + \delta_1$ vertical edges of any given depth.

(b) $D_m$ contains no consecutive horizontal edges if and only if $d_2 = 1$.

**Proof.** For $D_3$, both claims are immediate from Corollary 2.4(b). There are two possibilities for $D_3$. If $d_2 = 1$, the result for $D_2$ together with Corollary 2.4(c) shows $D_3$ contains no consecutive horizontal edges and that the vertical edges of $D_3$ all have different depths except $v_{d_1-1}$ and $v_{d_1}$, which both have depth $d_1 - 1$. 

For $d_2 > 1$, the result for $D_2$ together with Corollary 2.4(c) shows all vertical edges of $D_3$ have different depths. To see that $d_2 > 1$ implies there are consecutive horizontal edges, we need to consider two cases. When $d_1 > 1$, $D_3$ begins with a copy of $D_2$ by Corollary 2.4(c) and thus contains consecutive horizontal edges. When $d_1 = 1$, we must have $d_2 \geq 4$. But then $D_3$ is just $D_2 \setminus D_1$ and, since $d_2 \geq 4$, it contains consecutive horizontal edges.

For $m \geq 4$, both claims follow by induction using Corollary 2.4(c).

Analogous statements hold for $D'_{m}$, with horizontal edges $H'_m = \{h'_1, \ldots, h'_{um_{m,2}}\}$ and vertical edges $V'_m = \{v'_1, \ldots, v'_{um_{m-1,1}}\}$, by interchanging the roles of $d_1$ and $d_2$.

For $m = 3$, define the following subsets of $H_{m}$ and $V_{m}$:

- $H_{m,r} = \{h_{(r-1)um_{m-1,1}}, h_{(r-1)um_{m-1,1}+1}, \ldots, h_{rum_{m-1,1}}\}$;
- $V_{m,r} = \{v_{(r-1)um_{m,2}}, v_{(r-1)um_{m,2}+1}, \ldots, v_{rum_{m,2}}\}$.

We identify these, for each $r$, with the horizontal and vertical edges of $D_{m-1}$. Also set

- $H_{m,d_m-\delta_m} = \{h_{(d_m-\delta_m)um_{m-1,1}}, \ldots, h_{um_{m,1}}\}$;
- $V_{m,d_m-\delta_m} = \{v_{(d_m-\delta_m)um_{m-1,2}}, \ldots, v_{um_{m,2}}\}$.

We identify these subsets with the horizontal and vertical edges of $D_{m-1} \setminus D_{m-2-\delta_m}$.

As a notational convenience, for $1 \leq r \leq d_m - 1 - \delta_m$ and $1 \leq i \leq um_{m-1,1}$ we write $h_{i,r} := h_{(r-1)um_{m-1,1}+i}$ and similarly $v_{i,r} := v_{(r-1)um_{m,2}+i}$ for $1 \leq r \leq um_{m-2,2}$.

Let $\omega : E_m \to \mathbb{Z}_{\geq 0}$ be a $(d_1, d_2)$-bounded grading of $D_m$, $m \geq 1$. It will be convenient to write $\omega_H$ and $\omega_V$ for the restrictions of $\omega$ to $H_m$ and to $V_m$, respectively. In the absence of a total grading $\omega$, we refer to the maps $\omega_H : H_m \to [0, d_1]$ and $\omega_V : V_m \to [0, d_2]$ respectively as horizontal gradings and vertical gradings of $D_m$. We often consider $\omega$ to be the pair $(\omega_H, \omega_V)$ and refer to $\omega_H$ and $\omega_V$ as being compatible if Definition 1.2 is satisfied for $\omega$. Since the first condition (HGC) of Definition 1.2 only involves $\omega_H$, we refer to it as the horizontal grading condition. Similarly, we refer to the second condition (VGC) as the vertical grading condition.

Write $\supp(\omega) := \{e \in E_m : \omega(e) \neq 0\}$ and call this the support of $\omega$. Set $\supp(\omega_H) := \supp(\omega) \cap H$ and $\supp(\omega_V) := \supp(\omega) \cap V$. Define $|\omega|_H := \sum_{h \in H_m} \omega_H(h)$ and $|\omega|_V := \sum_{v \in V_m} \omega_V(v)$.

3. Combinatorics of compatible pairs

Let $\omega : E_m \to \mathbb{Z}_{\geq 0}$ be a $(d_1, d_2)$-bounded grading of $D_m$, $m \geq 1$. It will be convenient to write $\omega_H$ and $\omega_V$ for the restrictions of $\omega$ to $H_m$ and to $V_m$, respectively. In the absence of a total grading $\omega$, we refer to the maps $\omega_H : H_m \to [0, d_1]$ and $\omega_V : V_m \to [0, d_2]$ respectively as horizontal gradings and vertical gradings of $D_m$. We often consider $\omega$ to be the pair $(\omega_H, \omega_V)$ and refer to $\omega_H$ and $\omega_V$ as being compatible if Definition 1.2 is satisfied for $\omega$. Since the first condition (HGC) of Definition 1.2 only involves $\omega_H$, we refer to it as the horizontal grading condition. Similarly, we refer to the second condition (VGC) as the vertical grading condition.

Write $\supp(\omega) := \{e \in E_m : \omega(e) \neq 0\}$ and call this the support of $\omega$. Set $\supp(\omega_H) := \supp(\omega) \cap H$ and $\supp(\omega_V) := \supp(\omega) \cap V$. Define $|\omega|_H := \sum_{h \in H_m} \omega_H(h)$ and $|\omega|_V := \sum_{v \in V_m} \omega_V(v)$.

3.1. Shadow Statistics. To begin we introduce notation to gain a more delicate grasp of the compatibility conditions (HGC) and (VGC) from Definition 1.2. For a horizontal grading $\omega_H : H_m \to [0, d_1]$ and any subpath $ee' \subset D_m$, define the horizontal shadow statistic

$$f_{\omega_H}(ee') := -|ee'|_V + \sum_{h \in (ee')_H} \omega_H(h).$$

We also define the vertical shadow statistic

$$f_{\omega_V}(ee') := -|ee'|_H + \sum_{v \in (ee')_V} \omega_V(v).$$
for each vertical grading $\omega_V : V_m \to [0, d_2]$. It immediately follows from the definitions that the shadow statistics satisfy the following additivity property with respect to concatenation of paths:

(8) $f_{\omega_H}(e_1e_3) = f_{\omega_H}(e_1e_2) + f_{\omega_H}(e_2e_3)$ and $f_{\omega_V}(e_1e_3) = f_{\omega_V}(e_1e_2) + f_{\omega_V}(e_2e_3)$

for edges $e_1 \in E_m$ with $e_2 \in e_1e_3$.

The shadow statistics give the following alternative check for compatibility.

**Lemma 3.1.** Let $\omega : E_m \to \mathbb{Z}_{\geq 0}$ be a compatible grading of $D_m$. For $h \in H_m$ and $v \in V_m$, the following hold:

(a) if $f_{\omega_H}(hv) < 0$, then the horizontal grading condition (HGC) is satisfied for the path $hv$;

(b) if $f_{\omega_V}(hv) < 0$, then the vertical grading condition (VGC) is satisfied for the path $hv$.

**Proof.** We prove (a), the proof of (b) is similar.

There is nothing to show when $\omega_H(h) = 0$, so assume $h \in \text{supp}(\omega_H)$. Then $f_{\omega_H}(hh) > 0$ and as $e$ ranges from $h$ to $v$ the value of $f_{\omega_H}(he)$ either increases, stays the same, or decreases by 1 with each step. Since $f_{\omega_H}(hv) < 0$, we see that $f_{\omega_H}(he)$ must eventually take the value 0 with $e \neq v$, i.e. the horizontal grading condition is satisfied for the path $hv$. □

Apart from their relationship to the compatibility conditions (HGC) and (VGC), the shadow statistics $f_{\omega_H}$ and $f_{\omega_V}$ encode the following important information. For each subpath $ee' \subset D_m$, we obtain a factor $Y_{ee'}(\omega_H, \omega_V)$ of the monomial $Y_{D_m}(\omega_H, \omega_V)$ appearing in equation (5) by only multiplying the weights of edges along the path $ee'$.

**Lemma 3.2.** The quantities $f_{\omega_H}(ee')$ and $f_{\omega_V}(ee')$ record the total $Y$-degree and the total $X$-degree respectively of the monomial $Y_{ee'}(\omega_H, \omega_V)$.

**Proof.** A horizontal edge $h \in (ee')_H$ contributes a factor of $p_1\omega_H(h) Y^{\omega_H(h)} X^{-1}$ to $Y_{ee'}(\omega_H, \omega_V)$ while a vertical edge $v \in (ee')_V$ contributes a factor of $p_2 \omega_V(v) X^{\omega_V(v)+1} Y^{-1} X^{-1}$. The result now follows by comparing the total $Y$- and $X$-degrees of $Y_{ee'}(\omega_H, \omega_V)$ with the definitions of $f_{\omega_H}(ee')$ and $f_{\omega_V}(ee')$ respectively. □

For a horizontal grading $\omega_H : H_m \to [0, d_1]$, define the local shadow path $D(h; \omega_H)$ of a horizontal edge $h \in H_m$ to be the shortest nonempty subpath $he \subset D_m$ such that $f_{\omega_H}(he) = 0$, if there is no such subpath we set $D(h; \omega_H) = hv_{m-1, 2}$. Write $D_H(h; \omega_H) := D(h; \omega_H) \cap H_m$ and $D_V(h; \omega_H) := D(h; \omega_H) \cap V_m$ for the local horizontal shadow and local vertical shadow of $h$ with respect to $\omega_H$. The local shadow path $D(v; \omega_V)$ is defined similarly for a vertical edge $v \in V_m$ and a vertical grading $\omega_V : V_m \to [0, d_2]$, where $D(v; \omega_V) = hv$ if there is no edge $e \leq v$ for which $f_{\omega_V}(ev) = 0$. The local shadows $D_H(v; \omega_V), D_V(v; \omega_V)$ are defined as above.

By definition we have $f_{\omega_H}(D(h; \omega_H)) = 0$ whenever the final edge of $D(h; \omega_H)$ is not $v_{m-1, 2}$. More importantly, writing $D(h; \omega_H) = he$, Lemma 3.1 together with equation (8) imply that $f_{\omega_H}(he') > 0$ and $f_{\omega_H}(e'e) < 0$ for any proper subpaths $he', e'e \subset D(h; \omega_H)$. Thus we see for $h \in \text{supp}(\omega_H)$ and $v \in D_V(h; \omega_H)$ that the condition (HGC) is not satisfied for the path $hv$; however for any $\omega_V$ compatible with $\omega_H$ the condition (VGC) is satisfied for $h$ and $v$. In particular, when $\omega_V$ is compatible with $\omega_H$, $D(v; \omega_V)$ is a proper subpath of $D(h; \omega_H)$ for any $v \in D_V(h; \omega_H)$.

Similar statements hold using the vertical shadow statistic $f_{\omega_V}$. 

*Algebraic Combinatorics*, Vol. 2 #6 (2019)
3.2. Recursions. We introduce in this section a recursive construction of gradings analogous to the recursive operations on Dyck paths from Lemma 2.3.

The shadow of a horizontal grading $\omega_H : H_m \rightarrow [0,d_1]$ is the collection of vertical edges in the local vertical shadows of all horizontal edges, i.e. $\text{sh}(\omega_H) = \bigcup_{h \in H_m} D_V(h; \omega_H)$. The remote shadow of a horizontal grading $\omega_H : H_m \rightarrow [0,d_1]$ is the subset $\text{rsh}(\omega_H) \subset \text{sh}(\omega_H)$ obtained by excluding for each $d$ the (up to) $\omega_H(h_d)$ vertical edges of depth $d$ immediately following $h_d$. The shadow and remote shadow of a vertical grading $\omega_V : V_m \rightarrow [0,d_2]$ are defined similarly.

Remark 3.3. The remote shadow $\text{rsh}(\omega_H) \subset \text{sh}(\omega_H)$ of a horizontal grading $\omega_H$ can be described as the subset consisting of those vertical edges $v \in \text{sh}(\omega_H)$ for which there exists a vertical grading $\omega_V$ compatible with $\omega_H$ such that $\omega_V(v) > 0$. In particular, any vertical grading $\omega_V$ compatible with $\omega_H$ must satisfy $\omega_V(v) = 0$ for $v \in \text{sh}(\omega_H) \setminus \text{rsh}(\omega_H)$.

In order to give a relationship between gradings of $D_m$ and gradings of $D_{m+1}$, we need to partition the remote shadows according to which local shadow contains a given edge.

Definition 3.4. Let $\omega : E_m \rightarrow \mathbb{Z}_{\geq 0}$ be a grading of $D_m$.

(a) For $1 \leq j ≤ d ≤ u_{m,1}$, denote by $\text{rsh}(\omega_H)_{j,d}$ the set of $v \in \text{rsh}(\omega_H)$ of depth $d$ such that $v \in D_V(h_j; \omega_H)$ and $h_j$ is the first horizontal edge before $v$ with this property. Define the local remote shadow of the edge $h_j$ as $\text{rsh}(h_j; \omega_H) := \prod_{d \in [j+1,u_{m,1}]} \text{rsh}(\omega_H)_{j,d}$.

(b) For $0 ≤ \ell < t ≤ u_{m-1,2}$, denote by $\text{rsh}(\omega_V)_{t,\ell}$ the set of $h \in \text{rsh}(\omega_V)$ of height $\ell$ such that $h \in D_H(v_t; \omega_V)$ and $v_t$ is the first vertical edge after $h$ with this property. Define the local remote shadow of the edge $v_t$ as $\text{rsh}(v_t; \omega_V) := \prod_{\ell \in [t+1,t+2]} \text{rsh}(\omega_V)_{t,\ell}$.

Remark 3.5. By the definition of the remote shadows, it is impossible to have $d = j$ or $\ell = t-1$ in Definition 3.4.

Lemma 2.3 establishes a canonical order preserving bijection between the vertical edges $V_{m,1}'$ of $D_{m,1}$ and the horizontal edges $H_m$ of $D_m$ which we write as $\varphi = \varphi_{m} : V_{m,1}' \rightarrow H_m$, $\varphi'(v') = h_1$ for $1 \leq i \leq u_{m,1}$. Thus we obtain a bijection from $d_1$-bounded horizontal gradings of $D_m$ to $d_1$-bounded vertical gradings of $D_{m+1}$ taking a horizontal grading $\omega_H : H_m \rightarrow [0,d_1]$ to the vertical grading $\varphi^* \omega_H : V_{m,1}' \rightarrow [0,d_1]$ given by $\varphi^* \omega_H(v') = d_1 - \omega_H(h_1)$.

Remark 3.6. We will abuse notation slightly and also write $\varphi^*_m$ for the bijection between horizontal gradings of $D_m$ and vertical gradings of $D_{m+1}$ where the roles of $d_1$ and $d_2$ need to be interchanged in the definitions above, however this abuse should not lead to any confusion.

The next result shows that the remote shadows for $\omega_H$ and $\varphi^* \omega_H$ are intimately related.

Lemma 3.7 ([10, Corollary 4.18]). Let $\omega_H : H_m \rightarrow [0,d_1]$ be a horizontal grading of $D_m$. For $1 \leq j < d \leq u_{m,1}$, we have $|\text{rsh}(\omega_H)_{j,d}| = |\text{rsh}(\varphi^* \omega_H)_{d,j-1}|$.

Thus for $1 \leq j < d \leq u_{m,1}$ we may define a bijection $\theta_{j,d} : \text{rsh}(\omega_H)_{j,d} \rightarrow \text{rsh}(\varphi^* \omega_H)_{d,j-1}$ which preserves the natural order determined by distance from $h_j$ and from $v'_d$ respectively. More explicitly, as the vertical edges of $\text{rsh}(\omega_H)_{j,d}$ are read from bottom to top the corresponding horizontal edges of $\text{rsh}(\varphi^* \omega_H)_{d,j-1}$ are read from right to left.
For a horizontal grading \( \omega_H : H_m \to [0, d_1] \), write \( \mathcal{G}(\omega_H) \) for the collection of all \((d_1, d_2)\)-bounded gradings \( \omega : E_m \to \mathbb{Z}_{\geq 0} \) such that the restriction \( \omega|_{H_m} \) is precisely \( \omega_H \) and denote by \( \mathcal{C}(\omega_H) \subset \mathcal{G}(\omega_H) \) the subset of compatible gradings. Let \( \mathcal{G}_{\text{rsh}}(\omega_H) \subset \mathcal{G}(\omega_H) \) denote those gradings \( \omega \) for which \( \omega(v) = 0 \) whenever \( v \in V_m \setminus \text{rsh}(\omega_H) \) and write \( \mathcal{C}_{\text{rsh}}(\omega_H) := \mathcal{G}_{\text{rsh}}(\omega_H) \cap \mathcal{C}(\omega_H) \). Define analogous collections of gradings associated to a vertical grading \( \omega_V : V_m \to [0, d_2] \).

Define a map \( \Omega = \Omega_m : \mathcal{G}_{\text{rsh}}(\omega_H) \to \mathcal{G}_{\text{rsh}}(\varphi^* \omega_H) \) as follows:

\[
\Omega(\omega_V)(h') = \begin{cases} 0 & \text{if } h' \in H_{m+1} \setminus \text{rsh}(\varphi^* \omega_H); \\
\omega_V(v) & \text{if } h' = \theta_{j,d}(v) \text{ for } v \in \text{rsh}(\omega_H)_{j,d}.
\end{cases}
\]

Note that \( \Omega \) admits an obvious inverse map.

**Remark 3.8.** Given a grading \( \omega : E_m \to \mathbb{Z}_{\geq 0} \) of \( D_m \) where \( \omega_V \notin \mathcal{G}_{\text{rsh}}(\omega_H) \), the map \( \Omega \) may still be applied to \( \omega_V \) to produce a horizontal grading in \( \mathcal{G}_{\text{rsh}}(\varphi^* \omega_H) \). This observation will be used without mention in the statements of Lemma 3.9 and Proposition 3.16 as well as in the proof of Corollary 3.23.

The following result shows that we have some control over the shadow statistics under this operation. It is also the essential ingredient for understanding the piecewise compatible gradings introduced in the next section.

**Lemma 3.9** ([10, Lemma 4.19]). Let \( \omega : E_m \to \mathbb{Z}_{\geq 0} \) be a grading on \( D_m \). Suppose \( h' = \theta_{j,d}(v) \) for a vertical edge \( v \in \text{rsh}(\omega_H)_{j,d} \cap \text{supp}(\omega_V) \). Then \( f_{\Omega(\omega_V)}(h'v') = f_{\omega_V}(h'v) \).

This crucial result also shows that \( \Omega \) restricts to a map \( \mathcal{C}_{\text{rsh}}(\omega_H) \to \mathcal{C}_{\text{rsh}}(\varphi^* \omega_H) \), i.e. that the pair \((\Omega(\omega_V), \varphi^* \omega_H)\) gives a compatible grading of \( D'_{m+1} \) exactly when \( \omega_V \in \mathcal{C}_{\text{rsh}}(\omega_H) \).

**Proposition 3.10** ([10, Lemma 4.20]). Let \( \omega_H : H_m \to [0, d_1] \) be a horizontal grading of \( D_m \). For a vertical grading \( \omega_V \in \mathcal{G}_{\text{rsh}}(\omega_H) \), we have \( \omega_V \in \mathcal{C}_{\text{rsh}}(\omega_H) \) if and only if \( \Omega(\omega_V) \in \mathcal{C}_{\text{rsh}}(\varphi^* \omega_H) \).

### 3.3. PIECEWISE COMPATIBILITY

Our goal in this section is to understand which gradings on \( D_m, m \geq 3 \), are obtained by gluing together compatible gradings on the \( D_{m-1} \) subpaths of \( D_m \) found in Corollary 2.4(c).

**Definition 3.11.** Fix \( m \geq 3 \). Consider \((d_1, d_2)\)-bounded compatible gradings \( \omega_r = (\omega_{H,r}, \omega_{V,r}) \) of \( D_{m-1} \) for \( 1 \leq r \leq d_m - \delta_m \). We assume

\[
\omega_{V,d_m-\delta_m}(v) = 0
\]

for \( v \) in the first \( D_{m-2-\delta_m} \) subpath of \( D_{m-1} \) and

\[
\omega_{H,d_m-\delta_m}(h) = \ell
\]

for \( h \) in the first \( D_{m-2-\delta_m} \) subpath of \( D_{m-1} \) if \( h \) is immediately followed by exactly \( \ell \) vertical edges inside \( D_{m-2-\delta_m} \).

Define a grading \( \omega : E_m \to \mathbb{Z}_{\geq 0} \) of \( D_m \) by

\[
\omega(e) = \begin{cases} \omega_{H,r}(e) & \text{if } e \in H_{m,r}; \\
\omega_{V,r}(e) & \text{if } e \in V_{m,r};
\end{cases}
\]

where we identify subsets of edges in \( D_m \) with edges of \( D_{m-1} \) as in Definition 2.9. We will refer to any grading on \( D_m \) obtained in this way as piecewise compatible.

**Remark 3.12.** Every compatible grading of \( D_m, m \geq 3 \), is piecewise compatible. Given any grading \( \omega \) of \( D_m \) and \( 1 \leq r \leq d_m - \delta_m \), we will denote by \( \omega_r = (\omega_{H,r}, \omega_{V,r}) \) the grading of \( D_{m-1} \) obtained by restricting \( \omega \) to the \( r \)-th copy of \( D_{m-1} \) inside \( D_m \), where \( \omega_{d_m-\delta_m} = (\omega_{H,d_m-\delta_m}, \omega_{V,d_m-\delta_m}) \) denotes the grading on \( D_{m-1} \) satisfying the conditions (9) and (10) of Definition 3.11.
Remark 3.13. When considering piecewise compatible gradings \( \omega : E_m \to \mathbb{Z}_{\geq 0} \) of \( D_m \) we will instead make the following assumptions on the gradings \( \omega_{H'}, \omega_{d_i - \delta_m} \) and \( \omega_{V'}, \omega_{u_i - \delta_m} \) of \( D_{m-1} \):

\[
\omega_{H'} \cdot d'_m - \delta_m (h') = 0
\]

for \( h' \) in the first \( D'm_{2-\delta_m} \) subpath of \( D_{m-1} \) and

\[
\omega_{V'} \cdot d'_m - \delta_m (v') = d
\]

for \( v' \) in the first \( D'm_{2-\delta_m} \) subpath of \( D_{m-1} \). If \( v' \) is immediately preceded by exactly \( d \) horizontal edges inside \( D_{m-1} \).

The next result shows that only the final edge of \( D_m \) needs to be considered in order to verify (global) compatibility of a piecewise compatible grading.

**Lemma 3.14.** Let \( \omega : E_m \to \mathbb{Z}_{\geq 0} \) be a piecewise compatible grading on \( D_m \), \( m \geq 3 \). Then one of the compatibility conditions (HGC) or (VGC) is satisfied for every \( h \in H_m \) and every \( v \in V_{m,s} \), for \( 1 \leq r < s \leq d_m - 1 - \delta_m \). Since each pair \( (\omega_{H,r}, \omega_{V,r}) \) is compatible, it only remains to verify a compatibility condition for \( h \in \bigcup_{r=1}^{d_m-1-\delta_m} H_{m,r} \) and \( v \in V_{m,d_m-\delta_m} \).

**Proof.** Following [10, Remark 2.22], we have a principle of non-interaction between adjacent \( D_{m-1} \) subpaths of \( D_m \). More precisely, one of the compatibility conditions (HGC) or (VGC) will always be satisfied for paths \( hv \) with \( h \in H_{m,r} \) and \( v \in V_{m,s} \). Consequently, it only remains to verify a compatibility condition for \( h \in \bigcup_{r=1}^{d_m-1-\delta_m} H_{m,r} \) and \( v \in V_{m,d_m-\delta_m} \).

**Corollary 3.15.** When \( d_m = 1 \), every piecewise compatible grading of \( D_m \), \( m \geq 3 \), is compatible.

**Proof.** When \( d_m = 1 \), the set of horizontal edges \( \bigcup_{r=1}^{d_m-1-\delta_m} H_{m,r} \) is empty and thus the compatibility condition of Lemma 3.14 is trivially satisfied.

Next we observe that piecewise compatible gradings are well-behaved under the operations \( \varphi^* \) and \( \Omega \) introduced in Section 3.2.

**Proposition 3.16.** Let \( \omega : E_m \to \mathbb{Z}_{\geq 0} \) be a \((d_1, d_2)\)-bounded grading on \( D_m \) for \( m \geq 3 \). Then \( \omega \) is piecewise compatible if and only if \( (\Omega(\omega_V), \varphi^* \omega_H) \) is piecewise compatible.

**Proof.** We prove the forward implication, the other direction can be obtained by reversing the argument.

Assume \( \omega \) is piecewise compatible and, for \( 1 \leq r < d_m - \delta_m \), consider \( h' \in H_{m+1,r} \) and \( v' \in V_{m+1,r} \), with \( h' < v' \). If \( h' \notin D(v'_i; \varphi^* \omega_H) \), then the vertical grading condition (VGC) is satisfied for the path \( h'v'_i \). So we assume \( h' \in D(v'_i; \varphi^* \omega_H) \) and need to show that the horizontal grading condition (HGC) is satisfied for the path \( h'v'_i \).
Let \( v \) strongly left-justified at \( v \). We call \( \omega \) the vertical grading condition (VGC) is satisfied for the path \( h v \). That is, there exists \( e \in \mathbb{P}_i \) so that \( f_{\omega'}(ev) = 0 \). By piecewise compatibility, each vertical edge in \( h \mathbb{P} \) also satisfies the vertical grading condition with \( h \). It follows that \( f_{\omega'}(h v) < 0 \).

By Lemma 3.9, we thus have \( f_{\Omega(\omega)}(h'v'_c) < 0 \) and so the horizontal grading condition is satisfied for the path \( h'v'_c \) by Lemma 3.1. Since \( h'v'_c \) is an initial subpath of \( h'v'_c \), the horizontal grading condition is also satisfied for the path \( h'v'_c \). Since \( h' \) and \( v'_c \) were arbitrary, we see that \( (\Omega(\omega), \omega') \) is piecewise compatible.

We aim now to understand precisely when compatibility fails for a piecewise compatible grading. The definition below provides the necessary conditions for a piecewise compatible grading \( \omega \) constructed as in Definition 3.11 to be incompatible.

**Definition 3.17.** Let \( \omega_H : H_m \to [0, d_1] \) be a horizontal grading on \( D_m \), \( m \geq 3 \). We say a horizontal edge \( h \in H_m \) is blocking for \( \omega_H \) if the following hold:

- \( h \in H_m \setminus H_{m,d_1} \)
- \( D(h; \omega_H) = h v_{m-1,2} \)
- \( h \) is the maximal (i.e. furthest to the right) horizontal edge with these properties.

We call \( \omega_H \) left-justified at a blocking edge \( h \in H_m \) if there exists \( k \geq i \) so that \( \omega_H(h_i) > 0 \) for \( i \leq j < k \) and \( \omega_H(h_j) = 0 \) for \( j > k \). Such a horizontal grading is strongly left-justified at \( h \) if in addition the following hold:

- \( \omega_H(h_j) = d_1 \) for \( i \leq j < k \)
- \( f_{\omega'}(h_j v_{m-1,2}) = 0 \)

Let \( \omega_V : V_m \to [0, d_2] \) be a vertical grading on \( D_m \), \( m \geq 3 \). For a horizontal edge \( h_i \in H_m \), \( \omega_V \) is called right-justified with respect to \( h_i \) if there is a vertical edge \( v_s \in h_i v_{m-1,2} \) so that \( \omega_V(v_t) > 0 \) for \( s \leq t \leq u_{m-1,2} \) and \( \omega_V(v_t) = 0 \) for all vertical edges \( v_t \in (h_i \mathbb{P})_t \). Such a vertical grading is strongly right-justified with respect to \( h_i \) if in addition the following hold:

- \( \omega_V(v_t) = d_2 \) for \( s < t \leq u_{m-1,2} \)
- \( D(v_{u_{m-1,2}}; \omega_V) = h_i v_{m-1,2} \) with \( f_{\omega'}(h_i v_{m-1,2}) = 0 \).

**Proposition 3.18.** Let \( \omega : E_m \to \mathbb{Z}_{\geq 0} \) be a piecewise compatible grading of \( D_m \), \( m \geq 3 \), for which \( \omega_H \) admits the blocking edge \( h_i \in H_m \) and \( \omega_V \) is strongly right-justified with respect to \( h_i \). Then \( \omega_H \) is left-justified at \( h_i \) and \( \text{supp}(\omega_H) \cap h_i v_{m-1,2} = \text{rsh}(\omega_V) \cap h_i v_{m-1,2} \).

*Proof.* Since \( \omega_V \) is strongly right-justified with respect to \( h_i \), we have \( D(v_{u_{m-1,2}}; \omega_V) = h_i v_{m-1,2} \) and thus \( \text{supp}(\omega_H) \cap h_i v_{m-1,2} \subset \text{rsh}(\omega_V) \cap h_i v_{m-1,2} \). To see equality of these sets we show that they must have the same cardinality.

As \( \omega_V \) is strongly right-justified with respect to \( h_i \), we have \( \omega_V(v) = d_2 \) for each vertical edge \( v \in \mathbb{P}_s v_{m-1,2} \), where \( s = u_{m-1,2} = \left\lfloor \frac{u_{m-1,2} - 1}{d_2} \right\rfloor \). This implies \( \omega_H(h) = 0 \) for each horizontal edge \( h \in \mathbb{P}_s v_{m-1,2} \). Otherwise both grading conditions would fail for the path \( hv \), where \( v \) is the first vertical edge after \( h \), a contradiction with piecewise compatibility of \( \omega \).

Then observe that the vertical edge \( v \) has depth \( \left( u_{m-1,2} - \left\lfloor \frac{u_{m-1,2} - 1}{d_2} \right\rfloor \right) u_{m-1,2} \) by Lemma 2.7. Using once more that \( \omega_V \) is strongly right-justified with respect to \( h_i \),
we must also have \( \omega_H(h) = 0 \) for each of the \( u_{m,1} - i + 1 - d_2 \left\lfloor \frac{u_{m,1} - i + 1}{d_2} \right\rfloor \) horizontal edges \( h \) immediately preceding \( v_s \) in order for piecewise compatibility to hold.

The above discussion has shown that \( \omega_H(h_j) = 0 \) whenever \( j \) is larger than the following quantity:

\[
\left\lfloor \frac{u_{m,1} - i + 1}{d_2} \right\rfloor u_{m,1} - \left( u_{m,1} - i + 1 - d_2 \left\lfloor \frac{u_{m,1} - i + 1}{d_2} \right\rfloor \right) = i - 1 + \left\lfloor \frac{u_{m,1} - i + 1}{d_2} \right\rfloor u_{m,1} - d_2 \left\lfloor \frac{u_{m,1} - i + 1}{d_2} \right\rfloor
\]

where both equalities follow from the identity \([n+x] = n + \lfloor x \rfloor\) which holds for all real numbers \( x \) and all integers \( n \). This discussion also shows that \( h_1 v_{u_{m,1} - 2} \cap (\sh(\omega_V \setminus rsh(\omega_V)) = (h_1 + d v_{u_{m,1} - 1}) H, \) where \( d = \left\lfloor \frac{u_{m,1} - i + 1}{d_2} \right\rfloor u_{m,1} - 2 \). Since \( D(v_{u_{m,1} - 2}; \omega_V) = h_1 v_{u_{m,1} - 2} \), it follows that

\[
|\sh(\omega_V \setminus h_1 v_{u_{m,1} - 1})| = \left\lfloor \frac{u_{m,1} - i + 1}{d_2} \right\rfloor u_{m,1} - 1.
\]

Now observe the inequality

\[
\left\lfloor \frac{u_{m,1} - i + 1}{d_2} \right\rfloor u_{m,1} - \left( u_{m,1} - i + 1 \right) u_{m,1} - 1 \leq \left\lfloor \frac{u_{m,1} - i + 1}{d_2} \right\rfloor \frac{u_{m,1} - i + 1}{d_2} u_{m,1},
\]

where the equality can be deduced from the identities \(-\lfloor x \rfloor = \lceil -x \rceil\), \([n + x] = n + \lfloor x \rfloor\), and \(\left\lfloor \frac{x}{n} \right\rfloor = \left\lfloor \frac{x}{n} \right\rfloor\) which hold for all real numbers \( x \) and all positive integers \( n \).

But \( h_1 \) is blocking and \( \omega_H \) is \( d_1 \)-bounded so that

\[
|\text{supp}(\omega_H) \cap h_1 v_{u_{m,1} - 1}| \geq \left\lfloor \frac{h_1 v_{u_{m,1} - 1}}{d_1} \right\rfloor = \left\lfloor \frac{u_{m,1} - i + 1}{d_2} \right\rfloor u_{m,1} - 1 - \frac{(i-1)u_{m,1} - 1}{d_1}.
\]
Combining this observation with the inequalities leading up to equation (11), we see that

\[
|\text{supp}(\omega_H) \cap h_i v_{u_{m-1,2}}| \geq \left| \frac{u_{m-1,2} - \frac{(i-1)u_{m-1,2}}{u_{m,1}}}{d_1} \right| \geq \left| \frac{u_{m-1,2} - \frac{(i-1)u_{m-1,2}}{u_{m,1}}}{d_2} \right| = |\text{rsh}(\omega_V) \cap h_i v_{u_{m-1,2}}|.
\]

But either inequality being strict is impossible since \(\text{supp}(\omega_H)\) does not intersect \(\text{sh}(\omega_V) \setminus \text{rsh}(\omega_V)\). Thus \(\omega_H\) must be left-justified at \(h_i\) with

\[
|\text{supp}(\omega_H) \cap h_i v_{u_{m-1,2}}| = \left| \frac{u_{m-1,2} - \frac{(i-1)u_{m-1,2}}{u_{m,1}}}{d_1} \right| = \left| \frac{u_{m-1,2} - \frac{(i-1)u_{m-1,2}}{u_{m,1}}}{d_2} \right| = |\text{rsh}(\omega_V) \cap h_i v_{u_{m-1,2}}|.
\]

In particular, \(\text{supp}(\omega_H) \cap h_i v_{u_{m-1,2}} = \text{rsh}(\omega_V) \cap h_i v_{u_{m-1,2}}\).

Remark 3.19. The middle equality of equation (12) does not hold for all \(i\), this equality is a consequence of the hypotheses and thus provides a necessary condition for the existence of a piecewise compatible grading as in Proposition 3.18.

The next result will show that this condition is also sufficient and that such gradings are the only piecewise compatible gradings which are not compatible.

**Theorem 3.20.** Let \(\omega : E_m \to \mathbb{Z}_{\geq 0}\) be a piecewise compatible grading of \(D_m\), \(m \geq 3\).

(a) If \(\omega_H\) does not admit a blocking edge, then \(\omega\) is compatible.

(b) Suppose \(\omega_H\) admits a blocking edge \(h_i\) but \(\omega\) is not compatible. Then the following hold:

(i) \(D(v_{u_{m-1,2}}; \omega_V) = h_i v_{u_{m-1,2}}\) with \(f_{\omega_V}(h_i v_{u_{m-1,2}}) = 0\);

(ii) \(\omega_H\) is left-justified at \(h_i\) and \(\omega_V\) is strongly right-justified with respect to \(h_i\).

If in addition \(m \geq 4\), the following also hold:

(iii) \(f_{\omega_H}(h_i v_{u_{m-1,2}}) = 0\);

(iv) \(\omega_H\) must be strongly left-justified at \(h_i\);

(v) \(\text{ht}(h_{i+1}) = \text{ht}(h_i) + \delta_1\) when \(|\text{supp}(\omega_H) \cap h_i v_{u_{m-1,2}}| > 1\).

Remark 3.21. When \(d_m = 1\), the hypotheses of Theorem 3.20 cannot apply by Corollary 3.15.

**Proof.** If \(\omega_H\) does not admit a blocking edge, any horizontal edge \(h \in H_m\) has a local shadow path of the form \(D(h; \omega_H) = \text{he}\) with \(e < v_{u_{m-1,2}}\), i.e. the horizontal grading condition is satisfied for \(h\) and \(v_{u_{m-1,2}}\). By Lemma 3.14, this implies \(\omega\) is compatible. This establishes (a).

From now on we assume \(\omega_H\) admits a blocking edge \(h_i\) and \(d_m \neq 1\). There are two possible cases. First consider the case \(\text{ht}(h_i) \geq u_{m-1,2} - d_1\). Since by definition \(h_i\) is not contained in the final \(D_{m-1} \setminus D_{m-2} - \delta_m\) subpath of \(D_m\), we must have \(d_1 \geq 2\) and so this case can occur only if one of the following holds:

- \(m = 3\) with \(d_1 \neq 1\);
- \(m = 4\) with \(d_1, d_2 \neq 1\);
- \(m = 5\) with \(d_2 = 1\).
When $m = 4$ or $m = 5$ above, we must have $h_i = h_{u_{m-1,1}:d_{m-1}-1}$ (see Definition 2.9 for notation).

Let $\ell = \text{ht}(h_i)$. Then, since $d_1 \neq 1$ in all cases above, each vertical edge in $\overline{v}_{\ell+1}\overline{v}_{u_{m-1,2}}$ if $m = 3$ (resp. in $h_{i+1}v_{u_{m-1,2}}$ if $m = 4$ or $m = 5$) is immediately preceded by exactly $d_2$ horizontal edges inside $h_i v_{u_{m-1,2}}$ while $v_{u_{m-1,2}}$ is immediately preceded by exactly $d_2 - 1$ horizontal edges. In particular, we see that the horizontal grading condition fails for the path $h_i v_{u_{m-1,2}}$ exactly when:

- $\omega(v_{t+1}) = d(p(v_{t+1}) - i)$ and $\omega(v) = d_2$ for $v \in (\overline{v}_{t+1}\overline{v}_{u_{m-1,2}}) v$ for $m = 3$;
- $\omega(v) = d_2$ for all $v \in (h_i v_{u_{m-1,2}}) v$ for $m = 4$ or $m = 5$.

In either case we have $D(v_{u_{m-1,2}}; \omega(v)) = h_i v_{u_{m-1,2}}$ with $f_{\omega(v)}(h_i v_{u_{m-1,2}}) = 0$. Note that in each of the cases above, $\omega_H^i$ is left-justified at $h_i$ with $k = i$ in Definition 3.17 and $\omega^i$ is strongly right-justified with respect to $h_i$. This establishes the claims in the first part of (b) for these cases. Observe that our assumptions when $m = 4$ or $m = 5$ imply $f_{\omega_H^i}(h_i v_{u_{m-1,2}}) = 0$ and that $\omega_H^i$ is strongly left-justified at $h_i$. Since $\text{supp}(\omega_H^i) \cap h_i v_{u_{m-1,2}} = \{h_i\}$, this establishes the second part of (b) in these cases.

Now assume $m \geq 4$ and $\text{ht}(h_i) < u_{m-1,2} - d_1$. Then there must exist $j > i$ so that $D(h_j; \omega_H^i) = h_j v_{u_{m-1,2}}$ with $1 \leq \ell \leq \omega_H^i(h_i) - 1$ (the extra $d_1$ must be included here since $d_2 = 1$ implies all horizontal edges of $D_m$ have different heights, in other words $d_2 = 1$ implies $h_i$ is immediately followed by a vertical edge). Assume that $j$ is chosen so that $\ell$ is minimal, in particular when $d_1 = 1$ we must have $\ell = 1$. By Lemma 3.14, the vertical grading condition must be satisfied for the paths $h_j v$ with $v \in (h_j v_{u_{m-1,2}}) v$. For each such $v$, we have $D(v; \omega_H^i) = h_j v(v) v$ for some $j(v) = i$, in particular $f_{\omega_H^i}(h_j v(v)) = 0$. Since $h_j$ is blocking, it cannot be contained in the shadow of any of these vertical edges. Moreover, when $d_1 = 1$, the edge $h_j$ will also not be contained in the shadow of any of these vertical edges. Thus we see that there are at least $1 + d_2$ horizontal edges of the path $h_j v_{u_{m-1,2}}$ lying outside the shadows of its vertical edges and applying equation (8) shows $f_{\omega_H^i}(h_j v_{u_{m-1,2}} - 1) \leq -(1 + d_2)$. But by Corollary 2.4 there are $d_2 - 1 - d_2$ horizontal edges immediately preceding $v_{u_{m-1,2}}$ and, since $\omega_H^i(v_{u_{m-1,2}}) \leq d_2$, we must have $f_{\omega_H^i}(h_j v_{u_{m-1,2}} - 1) \leq 0$. We conclude that one of the following holds:

- $D(v_{u_{m-1,2}}; \omega(v))$ is a proper subpath of $h_i v_{u_{m-1,2}}$ by Lemma 3.1 and thus $\omega$ is compatible;
- $D(v_{u_{m-1,2}}; \omega(v)) = h_i v_{u_{m-1,2}}$ with $f_{\omega(v)}(h_i v_{u_{m-1,2}}) = 0$ and both compatibility conditions fail for the path $h_i v_{u_{m-1,2}}$.

This establishes claim (i) of (b) in this case. When $d_1 = 1$, we must have $f_{\omega_H^i}(h_j v_{u_{m-1,2}}) = 0$ for otherwise $h_i$ could not be blocking. This gives claim (iii) of (b) when $d_1 = 1$. To complete the proof of (ii) for $d_1 > 1$ and $m \geq 4$, we observe that $h_i$ being a blocking edge implies $f_{\omega_H^i}(h_i v_{u_{m-1,2}}) \geq 0$. Our aim then is to show that $f_{\omega_H^i}(h_i v_{u_{m-1,2}}) > 0$ implies the second situation above is impossible.

Indeed, $f_{\omega_H^i}(h_i v_{u_{m-1,2}}) > 0$ can only occur if we take $\ell \leq \omega_H^i(h_i) - 1 - d_1$ above. But, assuming $d_1 > 1$ and $m \geq 4$, there are $d_2$ horizontal edges of $D_m$ immediately preceding each of the vertical edges

$$v_{u_{m-1,2} - d_1 + 2 - d_1, v_{u_{m-1,2} - d_1 + 3 - d_1, \ldots, v_{u_{m-1,2} - 1}},$$

and $d_2 - 1$ horizontal edges immediately preceding $v_{u_{m-1,2}}$ (by Corollary 2.4, the terminal subpath of $D_m$ containing all these edges identifies with the terminal subpath $D_3 \setminus D_2$ inside $D_3$). It follows that $D(v_{u_{m-1,2}}; \omega(v))$ must be a subpath of $h_j v_{u_{m-1,2}}$ and so the vertical grading condition is satisfied for the path $h_j v_{u_{m-1,2}}$. In particular, $\omega$ is compatible by Lemma 3.14, this completes the proof of (iii).

The arguments above also establish the following when $m \geq 4$, $d_m \neq 1$, and $\text{ht}(h_i) < u_{m-1,2} - d_1$: Alajeck Combinatorics, Vol. 2 #6 (2019)
• if \( \omega_H(h_i) < d_1 \) or \( h_i \) is immediately followed by \( 1 + \delta_1 \) vertical edges, then either \( d_1 = 1 \) and \( h_i \) cannot possibly be blocking or there must exist a horizontal edge \( h_j \) as in the previous paragraph and compatibility again holds, this gives (v) once we have established (iv), i.e. once we know that \( \omega_H \) is strongly left-justified at \( h_i \);  
• if \( \omega_V(v_{um_{-1,2} - t}) < d_2 \) for any \( 0 \leq t \leq d_1 - \delta_1 \), then the piecewise compatible grading \( \omega \) must be compatible.

We prove (iii) and (iv) by induction on \( m \geq 3, d_m \neq 1 \). The base case \( m = 3 \) of (ii) was established in the first part of the proof. Suppose \( m \geq 4 \) and \( \omega \) is not compatible. By Proposition 3.16 the grading \( ((\varphi_{m-1}^*)^{-1} \omega_V, \Omega_{m-1}^{-1}(\omega_H)) =: (\omega_H^*, \omega_V^*) \) of \( D_{m-1}^\prime \) is piecewise compatible, but not compatible by Proposition 3.10. By part (a), there must be a blocking edge \( h'_j \) for \( \omega_H^* \). Applying (ii) to the grading \( (\omega_H^*, \omega_V^*) \) we see that \( \omega_H^* \) is left-justified at \( h'_j \) and \( \omega_V^* \) is strongly right-justified with respect to this blocking edge.

When \( m = 4 \), we have \( \text{supp}(\omega_H) \cap h'_j v'_{um_{-2,2}} = \{ h'_j \} \) and from the definition of \( \varphi_{m-1}^* \) we see that \( \omega_V \) is strongly right-justified with respect to \( h_i \). This requires the extra observation above that we had to take \( k = i \) in the definition of left-justification for the case \( m = 3 \). For \( m \geq 5 \), claim (iv) applied to the grading \( (\omega_H^*, \omega_V^*) \) shows that \( \omega_H^* \) is strongly left-justified at \( h'_j \) and again the definition of \( \varphi_{m-1}^* \) shows that \( \omega_V \) is strongly right-justified with respect to \( h_i \). By Proposition 3.18, we see that \( \omega_H \) must be left-justified at \( h_i \).

It remains to argue that \( \omega_H \) is strongly left-justified at \( h_i \), but this is immediate from Lemma 3.7 and the definition of the maps \( \theta \). Indeed, since \( \omega_H \) is strongly left-justified at its blocking edge \( h'_j \), the remote shadows of the horizontal edges in \( h'_j v'_{um_{-2,2}} \) are linearly ordered in the opposite order to the horizontal edges in \( \text{supp}(\omega_H) \cap h'_j v'_{um_{-2,1}} \). Since \( \omega_V \) is strongly right-justified with respect to \( h_i \), analogous statements can be made about the remote shadows of the vertical edges in \( h_i v_{um_{-1,2}} \). But the maps \( \theta \) are compatible with these orderings and so \( \omega_V \) being strongly right-justified with respect to \( h'_j \) forces \( \omega_H = \Omega_{m-1}(\omega_V^*) \) to be strongly left-justified at \( h_i \). This completes the proof of (ii) and (iv).

The next result severely restricts which horizontal edges can be blocking.

**Corollary 3.22.** Let \( \omega : E_m \to \mathbb{Z}_{\geq 0} \) be a piecewise compatible grading of \( D_m, m \geq 5 \), which is not compatible. Write \( h_i \in H_m \) for the blocking edge of \( \omega_H \). Then either \( i = 1 \) or \( h_i \) is immediately preceded by a vertical edge.

**Proof.** By Proposition 3.16 and Proposition 3.10, the grading \( (\omega_H^*, \omega_V^*) := ((\varphi_{m-1}^*)^{-1} \omega_V, \Omega_{m-1}^{-1} \omega_H) \) of \( D_{m-1}^\prime \) is piecewise compatible but not compatible. Let \( h'_j \in H'_{m-1} \) denote the blocking edge of \( \omega_H^* \). Then since \( m \geq 5 \), we have \( |\text{rsh}(h'_j, \omega_H^*)| = d_2 - \ell \), where \( \ell \) is the number of vertical edges immediately following \( h'_j \). By Lemma 3.7, this implies there are \( d_2 - \ell \) horizontal edges of height \( j - 1 \) in the remote shadow of \( \omega_V \). But there are exactly \( d_2 - \ell \) horizontal edges of height \( j - 1 \) inside \( D_m \) by Lemma 2.3. Since \( D(v_{um_{-1,2}}; \omega_V) = h_i v_{um_{-1,2}} \), the edge \( h_i \) lies furthest to the left among all horizontal edges in \( \text{rsh}(\omega_V) \cap h_i v_{um_{-1,2}} \), this gives the result. \( \square \)

We also obtain the following analogue of Proposition 3.18.

**Corollary 3.23.** Let \( \omega : E_m \to \mathbb{Z}_{\geq 0} \) be a piecewise compatible grading of \( D_m, m \geq 3 \), which is not compatible. If \( h_i \in H_m \) denotes the blocking edge for \( \omega_H \), then \( \text{supp}(\omega_V) \cap h_i v_{um_{-1,2}} = \text{rsh}(\omega_V) \cap h_i v_{um_{-1,2}} \).

**Proof.** Since \( \omega \) is not compatible, the grading \( (\Omega_m(\omega_V), \varphi_m^* \omega_H) := (\omega_H, \omega_V) \) of \( D_{m+1}^\prime \) is not compatible by Proposition 3.10, but is piecewise compatible by Proposition 3.16.
By Theorem 3.20 the grading \((\omega_H, \omega_V)\) satisfies the hypotheses of Proposition 3.18 and so \(\text{supp}(\omega_V) \cap h_i v_{um-1,2} \subseteq \text{rsh}(\omega_H) \cap h_i v_{um-1,2}\) since every vertical edge in \(\text{supp}(\omega_V) \cap h_i v_{um-1,2}\) is contained in the shadow of \(\omega_H\). If there exists \(v \in \text{rsh}(\omega_H) \cap h_i v_{um-1,2}\) with \(\omega_V(v) = 0\), by Lemma 3.7 there will be a horizontal edge \(h' \in \text{rsh}(\omega_V) \cap h'_j v'_{um-2}\) with \(\omega_H(h') = 0\), a contradiction. Therefore we must have \(\text{supp}(\omega_V) \cap h_i v_{um-1,2} = \text{rsh}(\omega_H) \cap h_i v_{um-1,2}\).

As a final consequence we show that the piecewise compatible gradings which are not compatible satisfy a certain upper bound property with respect to compatible gradings.

**Corollary 3.24.** Suppose \(\omega : E_m \rightarrow \mathbb{Z}_{\geq 0}\) is a piecewise compatible grading of \(D_m\), \(m \geq 3\), which is not compatible. Write \(h_i\) for the blocking edge of \(\omega_H\). Then the following hold:

(a) for any vertical grading \(\chi_V \in \mathcal{C}(\omega_H)\) and any edge \(v \in (h_i v_{um-1,2})_V\), we have \(\chi_V(v) \leq \omega_V(v)\):

(b) for any horizontal grading \(\chi_H \in \mathcal{C}(\omega_V)\) and any edge \(h \in (h_i v_{um-1,2})_H\), we have \(\chi_H(h) \leq \omega_H(h)\).

**Proof.** We begin by making a few basic observations which allow to deduce part (b) for \(D_m\) from part (a) for \(D_{m-1}\).

Consider a horizontal grading \(\chi_H \in \mathcal{C}(\omega_V)\) and suppose \(\omega_H(h) < \chi_H(h)\) for some \(h \in (h_i v_{um-1,2})_H\). This implies \(\omega_H(h) < d_i\) since we only consider \(d_i\)-bounded horizontal gradings. By Theorem 3.20, we have \(D(v_{um-1,2}; \omega') = h_i v_{um-1,2}\) and so every edge of \(h_i v_{um-1,2}\) is in the shadow of \(\omega_H\). Thus we have \(\text{supp}(\chi_H) \cap h_i v_{um-1,2} \subseteq \text{rsh}(\omega_H) \cap h_i v_{um-1,2}\), where the equality comes from Proposition 3.18. By Theorem 3.20, \(\omega_H\) is strongly left-justified at \(h_i\) and so the only edge \(h \in \text{supp}(\omega_H) \cap h_i v_{um-1,2}\) which could satisfy \(\omega_H(h) < d_i\) is \(h = h_{i-1+d}\), where \(d = |\text{supp}(\omega_H) \cap h_i v_{um-1,2}|\).

For \(m = 3\), we have \(\text{supp}(\omega_H) \cap h_i v_{um-1,2} = \{h_i\}\). Since the horizontal grading condition (HGC) of \(\omega_H\) is not satisfied for the path \(h_i v_{um-1,2}\), the inequality \(\omega_H(h_i) < \chi_H(h_i)\) implies the horizontal grading condition of \(\chi_H\) is also not satisfied for the path \(h_i v_{um-1,2}\). In particular, \((\chi_H, \omega_V)\) is not compatible, a contradiction.

For \(m \geq 4\), consider the compatible grading \((\omega_{H'}, \chi_{V'}) := ((\varphi_{m-1})^{-1} \omega_V, \Omega_{m-1}^{-1} \chi_H)\) of \(D_{m-1}\) (see Proposition 3.16) and the piecewise compatible grading \((\omega_{H'}, \omega_{V'}) := ((\varphi_{m-1})^{-1} \omega_V, \Omega_{m-1}^{-1} \omega_H)\) of \(D_{m-1}\) (see Proposition 3.16). By the definition of \(\Omega\), we have \(\chi_{V'}(\theta^{-1} h_{i-1+d}) = \chi_H(h_{i-1+d}) > \omega_H(h_{i-1+d}) = \omega_H(\theta^{-1} h_{i-1+d})\).

This contradicts part (a) applied to the grading \((\omega_{H'}, \omega_{V'})\) of \(D_{m-1}\) and so there can be no grading \(\chi_H\) as above. Thus part (b) holds for \(m\) once we have established part (a) for \(m-1\), \(m \geq 4\).

To continue we suppose there exists a vertical grading \(\chi_V \in \mathcal{C}(\omega_H)\) such that \(\chi_V(v) = \omega_V(v)\) for some \(v \in (h_i v_{um-1,2})_V\). As above, this implies \(0 < \omega_V(v) < d_2\) and thus \(v = v_{um-1,2-t+1}\), where \(t = |\text{supp}(\omega_V) \cap h_i v_{um-1,2}|\). In particular, we must have \(d_2 \geq 2\) and by Corollary 2.8 the Dyck path \(D_m\) has no consecutive vertical edges.

Note that, by Proposition 3.18, there are only two possibilities for the height of the edge \(h_{i-1+d}\). Either \(\text{ht}(h_{i-1+d}) = u_{m-1,2} - t\) so that \(v_{um-1,2-t+1} \in \text{rsh}(h_{i-1+d}; \omega_H)\) or \(\text{ht}(h_{i-1+d}) = u_{m-1,2} - t - 1\) with \(h_{i-1+d}\) immediately followed by a single vertical edge. In the latter case, \(\omega_H(h_{i-1+d}) > 1\) also implies \(v_{um-1,2-t+1} \in \text{rsh}(h_{i-1+d}; \omega_H)\).
If $v_{u_{m-1,2}-t+1} \in \text{rsh}(h_{i-1+d};\omega_H)$, the horizontal grading condition (HGC) is not satisfied for the path $h_{i-1+d}v_{u_{m-1,2}-t+1}$ and we have $D(v_{u_{m-1,2}-t+1};\omega_V) = h_{i-1+d}v_{u_{m-1,2}-t+1}$ by Proposition 3.18. But then for $\chi_V$ as above, the vertical grading condition (VGC) is not satisfied for the path $h_{i-1+d}v_{u_{m-1,2}-t+1}$. In particular, this implies $(\omega_H,\chi_V)$ is not compatible, a contradiction.

Thus we must have $h(h_{i-1+d}) = u_{m-1,2} - t - 1$ with $h_{i-1+d}$ immediately followed by exactly one vertical edge and $\omega_H(h_{i-1+d}) = 1$. Then, since $\omega_H$ is strongly left-justified at $h_i$, we have $v_{u_{m-1,2}-t+1} \in \text{rsh}(h_{i-2+d};\omega_H)$ and so the horizontal grading condition (HGC) is not satisfied for the path $h_{i-2+d}v_{u_{m-1,2}-t+1}$. If $h_{i-1+d} \in \text{rsh}(v_{u_{m-1,2}-t+1};\omega_V)$, we must have $D(v_{u_{m-1,2}-t+1};\omega_V) = h_{i-1+d}v_{u_{m-1,2}-t+1}$. But then for $\chi_V$ as above, the vertical grading condition (VGC) is not satisfied for the path $h_{i-2+d}v_{u_{m-1,2}-t+1}$. In particular, this implies $(\omega_H,\chi_V)$ is not compatible, a contradiction.

Thus the horizontal edge $h_{i-1+d}$ must lie beyond the shadow of $v_{u_{m-1,2}-t+1}$. By Proposition 3.18, there can be no horizontal edges of height $u_{m-1,2} - t$ in the remote shadow of $\omega_V$ and so we must have $\omega_V(v_{u_{m-1,2}-t+1}) = \ell$, where $\ell < d_2$ is the number of horizontal edges immediately preceding $v_{u_{m-1,2}-t+1}$. For $m = 3$, this can only occur for $t = 1$, but $v_{u_{m-1,2}}$ is immediately preceded by $d_2 - 1$ horizontal edges inside $D_3$ and thus $\omega$ is compatible, a contradiction.

So we must have $m \geq 4$. Consider the piecewise compatible grading $(\omega_H',\omega_V') := ((\varphi_{m-1})^{-1}\omega_H,\Omega_{m-1}\omega_H)$ of $D'_{m-1}$ (see Proposition 3.16). Since $\omega_V$ is strongly right-justified and $\omega_V(v_{u_{m-1,2}-t+1}) < d_2$, the last horizontal edge in $\text{supp}(\omega_H')$ must be $h'_{u_{m-1,2}-t+1}$ with $\omega_H'(h'_{u_{m-1,2}-t+1}) = d_2 - \ell$, this being exactly the number of vertical edges immediately following $h'_{u_{m-1,2}-t+1}$ by Lemma 2.3. Moreover, by Lemma 3.7, the first vertical edge $v'$ in $\text{rsh}(\omega_H')$ lies in the remote shadow of $h'_{u_{m-1,2}-t+1}$ and $\omega_V'(v') = 1$. By Corollary 3.23, $v'$ cannot be immediately preceded by a vertical edge. But then there exists $\chi_V$, with $\chi_V(v') = 2$ compatible with $\omega_H'$, a contradiction with part (b) for $D'_{m-1}$.

This contradiction shows there can be no vertical $\chi_V$ as above and thus proves (a).

\[\blacksquare\]

4. PROOF OF MAIN THEOREM

We begin this section with a general statement about non-commutative weights associated to certain gradings of an arbitrary (i.e. not necessarily maximal) Dyck path, here we make no boundedness assumptions on the gradings.

**Proposition 4.1.** Let $D$ be any Dyck path with edges $E = H \sqcup V$, where $H = \{h_1, \ldots, h_n\}$ with $a_1 \geq 1$ and $V = \{v_1, \ldots, v_\alpha\}$ denote the sets of horizontal and vertical edges of $D$. Write $E = \{1, 2, \ldots, a_1 + a_2\}$ for the edges of $D$ taken in the natural order. Let $\omega : E \to \mathbb{Z}_{\geq 0}$ be any grading of $D$. Given $q_{ij} \in \mathbb{R}$ for $i \in \{1, 2\}$ and $j \in \mathbb{Z}_{\geq 0}$, define non-commutative weights

\[\text{(13)}\]

\[
\text{wt}_\omega(e) = \begin{cases} 
q_1 \omega(e) Y^{\omega(e)} X^{-1} & \text{if } e \in H; \\
q_2 \omega(e) X^{\omega(e)+1} Y^{-1} & \text{if } e \in V;
\end{cases}
\]

and let $Y_D(\omega) = \text{wt}_\omega(1) \text{wt}_\omega(2) \cdots \text{wt}_\omega(a_1 + a_2)$. Assume $\omega$ is compatible and satisfies the following:

1. the local shadow path $D(h_1;\omega_H) = D$ with $f_{\omega_H}(D) = 0$;
2. for any other vertical grading $\chi_V \in C(\omega_H)$ and any vertical edge $v_i \in V$ so that $\chi_V(v_s) = \omega_V(v_s)$ for $s < t$, we have $\chi_V(v_t) \leq \omega_V(v_t).

Then $Y_D(\omega) = p X^{-1}$, where $p = \prod_{i=1}^{a_1} q_1 \omega(h_i) \cdot \prod_{t=1}^{a_2} q_2 \omega(v_t).$
Proof. We first note that the coefficient $p$ is immediate from the definition of the non-commutative edge weights in equation (13). Thus we assume all $q_{i,j} = 1$ for the remainder of the proof.

We work by induction on $a_2$. For $a_2 = 0$, assumption 1 implies $a_1 = 1$ and $\omega_H(h_1) = 0$. The claim follows in this case directly from the definition of the non-commutative edge weights in equation (13).

Suppose $a_2 \geq 1$ and consider $h_i \in \text{supp}(\omega_H)$ with $i$ maximal. Let $v_r \in V$ denote the next vertical edge after $h_i$, i.e. the path $h_i v_r$ consists of several consecutive horizontal edges, say $d$ of them, followed by a single vertical edge. By assumption 1, we have $r < a_2$. By assumption 2, we have $\omega_V(v_r) = d - 1$ so that

\[
\omega_V(v_r) = (Y^\omega_{H(h_i)} X^{-1})^{d-1} (X^d Y^{-1} X^{-1}) = Y^\omega_{H(h_i)-1} X^{-1}.
\]

Let $\tilde{D}$ be the Dyck path obtained from $D$ by replacing the path $h_i v_r$ by a single horizontal edge. Write $\tilde{E} = \tilde{H} \cup \tilde{V}$ for the edges of $\tilde{D}$, where $\tilde{H} = \{h_i, \ldots, h_{a_1-d+1}\}$ and $\tilde{V} = \{\tilde{v}_1, \ldots, \tilde{v}_{a_2-1}\}$ denote the horizontal and vertical edges of $\tilde{D}$. Define a grading $\tilde{\omega} : \tilde{E} \to \mathbb{Z}_{\geq 0}$ by

\[
\tilde{\omega}_H(h_i) = \begin{cases} 
\omega_H(h_i) & \text{if } j < i; \\
\omega_H(h_i) - 1 & \text{if } j = i; \\
0 & \text{if } j > i;
\end{cases} \quad \tilde{\omega}_V(\tilde{v}_s) = \begin{cases} 
\omega_V(v_s) & \text{if } s < r; \\
\omega_V(v_{s+1}) & \text{if } s \geq r.
\end{cases}
\]

It is not hard to see that $\tilde{\omega}$ satisfies assumptions 1 and 2, thus by induction we have $Y_{\tilde{D}}(\tilde{\omega}) = X^{-1}$. By (14), we have $Y_D(\omega) = Y_{\tilde{D}}(\tilde{\omega})$ and so $Y_D(\omega) = X^{-1}$ as desired. \qed

Now we turn to the proof of Theorem 1.3 and return to our standard boundedness assumptions on gradings.

Lemma 4.2. Let $\omega : E_m \to \mathbb{Z}_{\geq 0}$ be a piecewise compatible grading of $D_m$, $m \geq 3$, which is not compatible. Denote by $h_i \in H_m$ the blocking edge of $\omega_H$. Set

\[
d = |\text{supp}(\omega_H) \cap h_i v_{m-1,2}| \quad \text{and} \quad t = |\text{supp}(\omega_V) \cap h_i v_{m-1,2}|.
\]

Then for any $h \in (\tilde{H}, h_{i-1+d})_H$, we have $Y_D(h; \omega_H)(\omega) = pX^{-1}$, where $p = \omega_{D(h; \omega_H)}(h_{i-1+d}) = \omega_{D(h; \omega_H)}(h_{i-1+d})$.

Proof. Since $h_i$ is blocking, no local shadow path $D(h; \omega_H)$ for $h \in (\tilde{H}, h_{i-1+d})_H$ contains $v_{m-1,2}$. Thus Lemma 3.14 shows $\omega|_{D(h; \omega_H)}$ is compatible. By definition of local shadow paths, $\omega|_{D(h; \omega_H)}$ satisfies condition 1 of Proposition 4.1. Condition 2 follows directly from Corollary 3.24. The conclusion immediately follows since the only edges in $D(h; \omega_H)$ for $h \in (\tilde{H}, h_{i-1+d})_H$ whose non-commutative weights have nontrivial coefficients are $h_{i-1+d}$ and $v_{m-1,2-t+1}$. \qed

This leads to the following result which is key to our induction argument.

Corollary 4.3. Let $\omega : E_m \to \mathbb{Z}_{\geq 0}$ be a piecewise compatible grading of $D_m$, $m \geq 3$, which is not compatible. Write $h_i$ for the blocking edge of $\omega_H$ and assume $\tilde{f}_{\omega_H}(h_i; v_{m-1,2}) = 0$. Set

\[
d = |\text{supp}(\omega_H) \cap h_i v_{m-1,2}| \quad \text{and} \quad t = |\text{supp}(\omega_V) \cap h_i v_{m-1,2}|.
\]

Then $Y_{h_i v_{m-1,2}}(\omega) = p Y X^{-1} X^{-1}$, where $p = \omega_H(h_{i-1+d}) \omega_V(v_{m-1,2-t+1})$.

Proof. We distinguish two cases as in the proof of Theorem 3.20. First consider the case $\text{ht}(h_i) \geq u_{m-1,2} - d_1$ in which one of the following holds: $m = 3$ with $d_1 \neq 1$, $m = 4$ with $d_1, d_2 \neq 1$, or $m = 5$ with $d_2 \neq 1$. In each of these cases $\text{supp}(\omega_H) \cap h_i v_{m-1,2} = \{h_i\}$ and by assumption $\omega_H(h_i) = u_{m-1,2} - \text{ht}(h_i)$. We use the description of $\omega$ from the proof of Theorem 3.20 in each case.
For $m = 3$ with $d_1 \neq 1$, set $\delta = 1$ if $h_i$ is immediately followed by a vertical edge and $\delta = 0$ otherwise. Then we have

$$Y_{h_1v_{u_{m-1,2}}}(\omega) = (p_1,\omega_H(h_i)Y^{\omega_H(h_i)}X^{-1})(XY^{-1}X^{-1})^\delta (X^{-1})^{\omega_v(v_{u_{m-1,2,t+1}})}$$

$$\times (p_2,\omega_V(v_{u_{m-1,2,t+1}})X^{\omega_V(v_{u_{m-1,2,t+1}})+1}Y^{-1}X^{-1})$$

$$\times [(X^{-1})^{d_2}(X^{d_2+1}Y^{-1}X^{-1})]^{\omega_H(h_i)-2-\delta} (X^{-1})^{d_1} (X^{d_2+1}Y^{-1}X^{-1})$$

$$= p(Y^{\omega_H(h_i)-1-\delta}X^{-1})[XY^{-\omega_H(h_i)+2+\delta}X^{-1}] (X^2Y^{-1}X^{-1})$$

$$= pYXY^{-1}X^{-1}.$$  

For $m = 4$ with $d_1, d_2 \neq 1$ or $m = 5$ with $d_2 = 1$, we have $p = 1$ and so

$$Y_{h_1v_{u_{m-1,2}}}(\omega) = (Y^{d_1}X^{-1})(XY^{-1}X^{-1})^{1+\delta_1} [(X^{-1})^{d_1} (X^{d_1+1}Y^{-1}X^{-1})]^{d_1,2-\delta_1}$$

$$\times (X^{-1})^{d_1,1-\delta_1} (X^{d_1+1}Y^{-1}X^{-1})$$

$$= (Y^{d_1,1-\delta_1}X^{-1})[XY^{-d_1+2+\delta}X^{-1}] (X^2Y^{-1}X^{-1})$$

$$= pYXY^{-1}X^{-1}.$$  

Now suppose $ht(h_i) < u_{m-1,2} - d_1$ so that $|\text{supp}(\omega_H) \cap h_1v_{u_{m-1,2}}| > 1$ and, by Theorem 3.20(iii), $ht(h_{i+1}) = ht(h_i) + \delta_1$. By Lemma 4.2, we have $Y_{D(h_{i+1},\omega_H)}(\omega) = pX^{-1}$. As in the proof of Theorem 3.20, we have $\omega_H(h_i) = d_1$ and $\omega_V(v_{u_{m-1,2}}) = d_2$ for $0 \leq \ell \leq d_1 - \delta_1$. Combining these observations, we get

$$Y_{h_1v_{u_{m-1,2}}}(\omega) = (Y^{d_1}X^{-1})(XY^{-1}X^{-1})^{1+\delta_1} [(X^{-1})^{d_1} (X^{d_1+1}Y^{-1}X^{-1})]^{d_1,2-\delta_1}$$

$$\times [(X^{-1})^{d_1} (X^{d_1+1}Y^{-1}X^{-1})]^{d_1,2-\delta_1} (X^{-1})^{d_1} (X^{d_1+1}Y^{-1}X^{-1})$$

$$= p(Y^{d_1,1-\delta_1}X^{-1})[XY^{-d_1+2+\delta}X^{-1}] (X^2Y^{-1}X^{-1})$$

$$= pYXY^{-1}X^{-1}.$$  

For $m \geq 1$, we consider summands of $Y_{D_m}$ given as follows:

$$Y_{D_m} = \sum_{\omega_H, H \to [0,d_1]} Y_{D_m}(\omega_H), \quad Y_{D_m}(\omega_H) := \sum_{\omega_V \in C(\omega_H)} Y_{D_m}(\omega_H, \omega_V).$$

Our goal will be to understand the action of $F_{P_\omega}$ on each of these summands. The first step is given by the following factorization results which allow for an induction argument.

**Lemma 4.4.** Let $\omega_H : H_m \to [0,d_1]$ be a horizontal grading of $D_m$, $m \geq 3$. Write

$$Y_{D_m}^{pc}(\omega_H) = \sum_{\omega \in E_m \to \mathbb{Z}_{\geq 0}} Y_{D_m}(\omega),$$

where the sum ranges over piecewise compatible gradings $\omega$ of $D_m$ for which $\omega|_{H_m} = \omega_H$. Then there is the following factorization:

$$Y_{D_m}^{pc}(\omega_H) = Y_{D_m-1}(\omega_{H,1}) Y_{D_m-1}(\omega_{H,2}) \cdots Y_{D_m-1}(\omega_{H,d_m-1-\delta_m}) p X^{H_{m-2-\delta_m}} Y_{D_m-1}(\omega_{H,d_m-\delta_m}),$$

where

$$p = \begin{cases} (-2 |V_{m-2-\delta_m}|, H_{m-2-\delta_m}, -|V_{m-2-\delta_m}|, P_{1,2}, -|V_{m-2-\delta_m}|) & \text{if } d_2 = 1 \text{ and } m > 3; \\ (-1 |V_{m-2-\delta_m}|, P_{1,1}, -|V_{m-2-\delta_m}|) & \text{if } d_2 > 1 \text{ or } m = 3. \end{cases}$$

Algebraic Combinatorics, Vol. 2 #6 (2019)
Proof. By the assumptions on the horizontal grading $\omega_{H,d_{m}\rightarrow \delta_{m}}$ of $D_{m-1}$ from Definition 3.11, each term contributing to $Y_{D_{m-1}}(\omega_{H,d_{m}\rightarrow \delta_{m}})$ begins with the monomial $p^{-1}X^{-|H_{m-2}\rightarrow \delta_{m}}}$ associated to the initial $D_{m-2}\rightarrow \delta_{m}$ subpath of $D_{m-1}$. To see the coefficient $p^{-1}$, we observe the following:

- when $d_{2} > 1$, there are $|V_{m-2}\rightarrow \delta_{m}|$ horizontal edges of $D_{m-2}\rightarrow \delta_{m}$ which are immediately followed by a single vertical edge and all other horizontal edges are not immediately followed by any vertical edges;
- when $d_{2} = 1$, each horizontal edge is immediately followed by a vertical edge and so there are $|V_{m-2}\rightarrow \delta_{m}| - |H_{m-2}\rightarrow \delta_{m}|$ horizontal edges of $D_{m-2}\rightarrow \delta_{m}$ which are immediately followed by exactly two vertical edges (see Corollary 2.8) and the remaining $|H_{m-2}\rightarrow \delta_{m}| - |V_{m-2}\rightarrow \delta_{m}|$ horizontal edges are immediately followed by a single vertical edge.

Using the notation of Definition 2.9, for any grading $\omega : E_{m} \rightarrow \mathbb{Z}_{\geq 0}$ there is the factorization

$$Y_{D_{m}}(\omega) = Y_{h_{1,1}v_{m-2,\rightarrow 2,1}}(\omega) \cdot Y_{h_{1,d_{m}-1,\rightarrow \delta_{m},v_{m-2,\rightarrow 2,1}d_{m}-1,\rightarrow \delta_{m}}(\omega)} \cdot Y_{u_{m-2,\rightarrow \delta_{m},+1,\rightarrow \delta_{m},v_{m-2,\rightarrow 2,0}-\delta_{m}}(\omega)}.$$

The result then immediately follows from the definition of piecewise compatible gradings in Definition 3.11. \qed

Using Remark 3.13 instead of Definition 3.11, we obtain a similar factorization for piecewise compatible gradings of $D_{m+1}'$. Below we use the notation $Y'_{D_{m}'}(\omega_{\nu}) := \sum_{\omega_{\nu} \in C(\omega_{\nu})} Y'_{D_{m}'}(\omega_{H',\omega_{\nu}})$ for a vertical grading $\omega_{\nu} : V_{m}' \rightarrow [0,d_{1}]$. Note that $d_{m+1}' = d_{m}$, $d_{m}' = d_{m-1}$, and so $\delta_{m+1}' = \delta_{m}$ when $m \geq 3 + \delta_{m+1}'$.

**Lemma 4.5.** Let $\omega_{\nu} : V_{m+1}' \rightarrow [0,d_{1}]$ be a vertical grading of $D_{m+1}'$ for $m \geq 3 + \delta_{m+1}'$. Write

$$Y'_{D_{m+1}'}(\omega_{\nu}) = \sum_{\omega' : E_{m+1}' \rightarrow \mathbb{Z}_{\geq 0}} Y'_{D_{m+1}'}(\omega'),$$

where the sum ranges over piecewise compatible gradings $\omega'$ of $D_{m+1}'$ for which $\omega'\vert_{V_{m+1}'} = \omega_{\nu}$. Then there is the following factorization:

$$Y'_{D_{m+1}'}(\omega_{\nu}) = Y'_{D_{m}'}(\omega_{\nu,1})Y'_{D_{m}'}(\omega_{\nu,2}) \cdots Y'_{D_{m}'}(\omega_{\nu,\delta_{m}-1})pX_{Y'_{D_{m}'}(\omega_{\nu,d_{m}-1})X^{-1}Y'_{D_{m}'}(\omega_{\nu,d_{m}-\delta_{m}})},$$

where

$$p = \begin{cases} \frac{|H_{m-2}\rightarrow \delta_{m}|-2|H_{m-2}\rightarrow \delta_{m}|}{|V_{m-2}\rightarrow \delta_{m}|}, & \text{if } d_{2} = 1; \\ \frac{|H_{m-2}\rightarrow \delta_{m}|}{|V_{m-2}\rightarrow \delta_{m}|}, & \text{if } d_{2} > 1. \end{cases}$$

**Proof.** By the assumptions on the vertical grading $\omega_{\nu,d_{m}-\delta_{m}}$ from Remark 3.13, each term contributing to $Y'_{D_{m}'}(\omega_{\nu,d_{m}-\delta_{m}})$ begins with the monomial $p^{-1}X^{-|V_{m-1}-\delta_{m}|}X^{-1}$ associated to the initial $D'_{m-1}-\delta_{m}$ subpath of $D_{m}'$. The coefficient $p^{-1}$ here can be seen as follows. Applying Lemma 2.3(a), we see that the structure of $D'_{m-1}-\delta_{m}$ is determined by the structure of $D_{m-2}-\delta_{m}$ observed in the last part of the previous proof. More precisely, we have the following:

- when $d_{2} > 1$, there are $|V_{m-2}\rightarrow \delta_{m}|$ vertical edges of $D_{m-1}-\delta_{m}$ which are immediately preceded by $d_{1} - 1$ horizontal edges and all other vertical edges are immediately followed by $d_{1}$ horizontal edges;
when \( d_2 = 1 \), there are \( |V_{m-2-\delta_m}| - |H_{m-2-\delta_m}| \) vertical edges of \( D'_{m-1-\delta_m} \) which are immediately preceded by \( d_1 - 2 \) horizontal edges and the remaining \( 2|H_{m-2-\delta_m}| - |V_{m-2-\delta_m}| \) vertical edges are immediately preceded by \( d_1 - 1 \) horizontal edges.

Then observe that in the computation of \( Y_{D_m}^{\prime} (\omega_{V',m-\delta_m}) \) the coefficients are given by \( p_{2,d_1-k} = p_{1,k} \) for \( k = 1, 2 \).

The analogous factorization in the special case where \( m = 3 \) and \( \delta'_m = 1 \) is handled in the following result which is proven exactly as Lemma 4.4.

**Lemma 4.6.** Suppose \( d_2 = 1 \). Let \( \omega_{V'} : V'_4 \to [0,d_1] \) be a vertical grading of \( D'_4 \). Write

\[
Y_{D'_4}^{\prime \prime} (\omega_{V'}) = \sum_{\omega : E'_4 \to \mathbb{Z}_{\geq 0}} Y_{D'_4}^{\prime} (\omega'),
\]

where the sum ranges over piecewise compatible gradings \( \omega' \) of \( D'_4 \) for which \( \omega'|_{V'_4} = \omega_{V'} \). Then there is the following factorization:

\[
Y_{D'_4}^{\prime \prime} (\omega_{V'}) = Y_{D'_4}^{\prime} (\omega_{V',1}) Y_{D'_4}^{\prime} (\omega_{V',2}) \cdots Y_{D'_4}^{\prime} (\omega_{V',d_1-2}) X Y_{D'_4}^{\prime} (\omega_{V',d_1-1}).
\]

The factorizations above concerned sums over piecewise compatible gradings. Our goal is to understand sums over compatible gradings, however it will be easier to first focus on piecewise compatible gradings which are not compatible.

**Lemma 4.7.** Let \( \omega_{H} : H_m \to [0,d_1] \) be a horizontal grading of \( D_m \), \( m \geq 3 \), for which there exists a vertical grading \( \omega_{V'} : V_m \to [0,d_2] \) of \( D_m \) so that \( (\omega_H, \omega_{V'}) \) is piecewise compatible but not compatible. Write

\[
Y_{D_m}^{\prime \prime} (\omega_H) = \sum_{\omega : E_m \to \mathbb{Z}_{\geq 0}} Y_{D_m} (\omega),
\]

where the sum ranges over piecewise compatible gradings \( \omega \) of \( D_m \) which are not compatible and satisfy \( \omega|_{H_m} = \omega_H \). Let \( h_1 \in H_m \) denote the blocking edge of \( \omega_H \) and set

\[
d = |\text{supp}(\omega_H) \cap h_1 v_{m-1,2}| \quad \text{and} \quad t = |\text{supp}(\omega_{V'}) \cap h_1 v_{m-1,2}|.
\]

Let \( s = \left\lfloor \frac{t}{m-1,2} \right\rfloor \) denote the index so that \( h_1 \in H_{m,s} \). Define a horizontal grading \( \chi_H : H_{m-1} \to [0,d_1] \) of \( D_{m-1} \) with \( \chi_H(h) = \omega_{H,s}(h) \) for \( h \in (h_1, \overline{h_1})_H \) and \( \chi_H(h) = \ell \) for \( h \in (\ell v_{m-2,2}, \overline{\ell v_{m-2,2}})_H \) if \( h \) is immediately followed by exactly \( \ell \) vertical edges in this copy of \( D_{m-1} \). Then there is the following factorization:

\[
Y_{D_m}^{\prime \prime} (\omega_H) = Y_{D_{m-1}} (\omega_{H,1}) \cdots Y_{D_{m-1}} (\omega_{H,s-1}) Y_{D_{m-1}} (\chi_H) p_1 X^{|h_1 v_{m-2,2},1|} p_2 Y X Y^{-1} X^{-1},
\]

where \( p_2 = p_{1,\omega_H(h_1-1,4)} p_{2,d_2-\omega_{V'}(v_{m-1,2,1},1)} \) and

\[
p_1 = \begin{cases} p_{1,1} & \text{if } d_2 = 1; \\ p_{1,2} & \text{if } d_2 > 1. \end{cases}
\]

**Proof.** Using the notation of Definition 2.9, for any grading \( \omega : E_m \to \mathbb{Z}_{\geq 0} \) there is the factorization

\[
Y_{D_m} (\omega) = Y_{h_1,1} v_{m-2,2,1} (\omega) \cdots Y_{h_1,t-1} v_{m-2,2,t-1} (\omega) Y_{h_1,t} (\omega) Y_{h_1,v_{m-1,2}} (\omega).
\]

By definition of \( \chi_H \), every term of \( Y_{D_{m-1}} (\chi_H) \) ends with the monomial \( p_1^{-1} X^{-|h_1 v_{m-2,2},1|} \).
Theorem 3.20 shows that any piecewise compatible grading \( \omega : E'_m \to \mathbb{Z}_{\geq 0} \) of \( D'_m \) which is not compatible agrees with \( (\omega'_H, \omega'_V) \) on the path \( h_i v_{m-1, z} \). The result then immediately follows from Corollary 4.3 and the definition of piecewise compatible gradings in Definition 3.11.

The next result gives an analogous factorization for sums over piecewise compatible gradings of \( D'_{m+1} \) which are not compatible.

**Lemma 4.8.** Let \( \omega' : V'_{m+1} \to [0, d_1] \) be a vertical grading of \( D'_{m+1}, m \geq 3 \), for which there exists a horizontal grading \( \omega'_{H'} : H'_{m+1} \to [0, d_2] \) of \( D'_{m+1} \) so that \( (\omega'_{H'}, \omega'_V) \) is piecewise compatible but not compatible. Write

\[
Y^{nc}_{D'_{m+1}}(\omega') = \sum_{\omega : E'_{m+1} \to \mathbb{Z}_{\geq 0}} Y^{nc}_{D'_{m+1}}(\omega),
\]

where the sum ranges over piecewise compatible gradings \( \omega \) of \( D'_{m+1} \) which are not compatible and satisfy \( \omega|_{V'_{m+1}} = \omega'_V \). Let \( h_j' \in H'_{m+1} \) denote the blocking edge of \( \omega'_{H'} \), where \( \text{ht}(h_j') = i - 1 \), and set

\[
d = |\text{supp}(\omega'_V) \cap h_j' v_{m,2}'| \quad \text{and} \quad t = |\text{supp}(\omega'_{H'}) \cap h_j' v_{m,2}'|.
\]

Let \( s = \left\lceil \frac{t}{d_1} \right\rceil \) denote the index so that \( h_j' \in H'_{m+1,s} \). Define a horizontal grading \( \chi' : V' \to [0, d_1] \) of \( D'_m \) with \( \chi'(u') = \omega'_{s}(u') \) for \( u' \in (h_i' h_j')_V \) and \( \chi'(v') = t \) if \( v' \) is immediately preceded by exactly \( t \) horizontal edges in this copy of \( D'_m \). Then there is the following factorization:

\[
Y^{nc}_{D'_{m+1}}(\omega') = Y^{nc}_{D'_m}(\omega'_{V,1}) \cdots Y^{nc}_{D'_m}(\omega'_{V,s-1}) Y^{nc}_{D'_m}(\chi') p_1 X^{|h_j' v_{m-1,2}'|} Y X^{-1} \cdots p_2 Y X Y^{-1} X^{-1},
\]

where \( p_2 = p_1, d = \omega'(v_{m,2}' - d_1) \) and \( p_2, d_2 = \omega'(h_{j-1,i}) \) and

\[
p_1 = \begin{cases} \frac{|h_i v_{m-2,2}'|}{|v_{m-2,2}'|} & \text{if } d_2 = 1; \\ \frac{|h_i v_{m-2,2}'|}{|h_i v_{m-2,2}'|} & \text{if } d_2 > 1; \\ \frac{|h_i v_{m-2,2}'|}{|h_i v_{m-2,2}'|} & \text{if } d_2 = 1; \\ \frac{|h_i v_{m-2,2}'|}{|h_i v_{m-2,2}'|} & \text{if } d_2 > 1; \end{cases}
\]

with \( h_i v_{m-2,2}' \) being the subpath in the \( s \)-th copy of \( D_{m-1} \) inside \( D_m \).

**Proof.** By definition of \( \chi' \), every term of \( Y^{nc}_{D'_m}(\chi') \) ends with the monomial \( p_1^{-1} X Y^{-|h_j' v_{m-1,2}'|} X^{-1} \). To see the coefficient \( p_1^{-1} \), note that by Lemma 2.3 the structure of \( D'_m \) is determined by the structure of \( D_{m-1} \).

Theorem 3.20 shows that any piecewise compatible grading \( \omega : E'_{m+1} \to \mathbb{Z}_{\geq 0} \) of \( D'_{m+1} \) which is not compatible agrees with \( (\omega'_{H'}, \omega'_V) \) on the path \( h_i' v_{m,2}' \). The result then immediately follows from Corollary 4.3 and the definition of piecewise compatible gradings in Definition 3.11. \( \square \)

### 4.1. Proof of Main Theorem

We work by induction on \( m \geq 1 \). From the definition of the non-commutative weights in equation (4), we immediately see

\[
Y_{D_1} = P_1(Y) X^{-1} = F_{P_1}(Y) = Y_1
\]

and

\[
Y_{D_2} = \sum_{\ell=0}^{d_2} (P_1(Y) X^{-1})^{d_2-\ell} (X^{-1})^{\ell} \left( p_{2, d_2-\ell} X^{\ell+1} Y^{-1} X^{-1} \right) = P_2((P_1(Y) X^{-1}) X Y^{-1} X^{-1} = F_{P_1} F_{P_2}(Y) = Y_2.
\]
Write \( Y_{D_2} = \sum_{\omega_H : H_2 \to [0, d_1]} Y_{D_2}(\omega_H) \). We will show that \( F_{P_0}(Y_{D_2}(\omega_H)) = Y'_{D_3}(\varphi_2^*\omega_H) \) for each horizontal grading \( \omega_H : H_2 \to [0, d_1] \). Fix a horizontal grading \( \omega_H : H_2 \to [0, d_1] \). If \( \text{supp}(\omega_H) = \emptyset \), then

\[
Y_{D_3}(\omega_H) = (X^{-1})^{d_2} P_0(X) X Y^{-1} X^{-1}
\]

and so

\[
F_{P_0}(Y_{D_2}(\omega_H)) = (XY^{-1}X^{-1})^{d_2} (X P_0(Y) X^{-1})(XY X^{-1})(P_0(Y) X^{-1})^{-1} (XY^{-1}X^{-1})
\]

\[
= (XY^{-1}X^{-1})^{d_2} XY XY^{-1} X^{-1}
\]

\[
= (XY^{-1}X^{-1})^{d_2-1} X^2 Y^{-1} X^{-1}
\]

\[
= Y'_{D_3}(\varphi_2^*\omega_H).
\]

Suppose \( \text{supp}(\omega_H) \neq \emptyset \). Let \( h_i \) be the last horizontal edge in \( \text{supp}(\omega_H) \). Then \( (\omega_H, \omega_V) \) will be compatible if and only if \( \omega_V(v_1) \leq d_2 - i \). This gives

\[
Y_{D_2}(\omega_H) = (p_{1, \omega(h_1)} Y^\omega(h_1) X^{-1}) \cdots (p_{1, \omega(h_i)} Y^\omega(h_i) X^{-1}) (X^{-1})^{d_2-i} \sum_{\ell=0}^{d_2-i} p_{2, d_2-\ell} X^\ell Y^{-1} X^{-1}.
\]

Applying \( F_{P_0} \) gives

\[
F_{P_0}(Y_{D_2}(\omega_H)) = (p_{1, \omega(h_1)} (P_0(Y) X^{-1})^\omega(h_1) XY^{-1} X^{-1}) \cdots (p_{1, \omega(h_i)} (P_0(Y) X^{-1})^\omega(h_i) XY^{-1} X^{-1})
\]

\[
\times (XY^{-1}X^{-1})^{d_2-i} \sum_{\ell=0}^{d_2-i} p_{2, d_2-\ell} (XY X^{-1})^{\ell+1} (P_0(Y) X^{-1})^{-1} (XY^{-1}X^{-1})
\]

\[
= (P_0(Y) X^{-1})^{\omega(h_1)} (X^{-1})^{d_1-\omega(h_1)} (p_{1, \omega(h_1)} X^{d_1-\omega(h_1)+1} Y^{-1} X^{-1}) \cdots (P_0(Y) X^{-1})^{\omega(h_i)-1}
\]

\[
\times \left( \sum_{\ell=0}^{d_2-i} p_{2, d_2-\ell} X^{\ell} Y^{-1} \right) (X^{-1})^{d_1-\omega(h_1)} (p_{1, \omega(h_1)} X^{d_1-\omega(h_1)+1} Y^{-1} X^{-1})
\]

\[
= Y'_{D_3}(\varphi_2^*\omega_H).
\]

Suppose \( m \geq 3 \) and let \( \omega_H : H_m \to [0, d_1] \) be a horizontal grading of \( D_m \). Following Theorem 3.20, there are two cases to consider.

(a) Suppose that \( (\omega_H, \omega_V) \) is compatible for every piecewise compatible grading \( (\omega_H, \omega_V) \) of \( D_m \). Then Lemma 4.4 shows there is the factorization

\[
(\dagger) \quad Y_{D_m}(\omega_H) = Y_{D_{m-1}}(\omega_{H, 1}) Y_{D_{m-1}}(\omega_{H, 2}) \cdots Y_{D_{m-1}}(\omega_{H, d_m-1-\delta_m}) p X^{\mid H_{m-2-\delta_m} \mid} Y_{D_{m-1}}(\omega_{H, d_m-\delta_m}),
\]

where

\[
p = \begin{cases} p_{1, 1} |V_{m-2-\delta_m}| - 2 |H_{m-2-\delta_m}| & p_{1, 2} |H_{m-2-\delta_m}| - |V_{m-2-\delta_m}| \text{ if } d_2 = 1; \\
p_{1, 1} |V_{m-2-\delta_m}| & p_{1, 2} |H_{m-2-\delta_m}| \text{ if } d_2 > 1.
\end{cases}
\]

If \( m \geq 3 + \delta_{m+1} \), we may apply Lemma 4.5 to conclude by induction that

\[
F_{P_0}(Y_{D_m}(\omega_H)) = Y'_{D_{m+1}}(\varphi_2^*\omega_H).
\]

It remains to consider the case \( m = 3 \) with \( \delta_3 = 1 \), i.e. \( d_2 = 1 \). In this case \( D_2 \) consists of a single horizontal edge followed by a single vertical edge and, by Corollary 2.4(c), \( D_3 \) consists of \( d_1 - 1 \) copies of \( D_2 \) followed

Algebraic Combinatorics, Vol. 2 #6 (2019)
by a single vertical edge, in particular $D_3$ ends with two consecutive vertical edges. The factorization (1) still holds in this case and by induction we have $F_{P_0}(Y_{D_2}(\omega_H,r)) = Y_{D_2}'(\varphi_2^r \omega_H)$ for $1 \leq r \leq d_1$. In particular, by Lemma 4.6 to see that $F_{P_0}(Y_{D_2}(\omega_H)) = Y_{D_2}'(\varphi_3^r \omega_H)$ it suffices to compare $F_{P_0}(Y_{D_2}(\omega_H,d_1-1)p_X Y_{D_2}(\omega_H,d_1))$ with $X Y_{D_2}'(\omega_{V',d_1-1})$, where we write $\omega_{V'} = \varphi_3^r \omega_H$.

There are two cases to consider. If $\omega(h_{d_1-1}) = 0$, we have $Y_{D_2}(\omega_H,d_1-1) = (X^{-1})p_X(X)XY^{-1}X^{-1}$ and so

$$F_{P_0}(Y_{D_2}(\omega_H,d_1-1)) = (XY^{-1}X^{-1})(X^{-1})p_X(Y)X^{-1}(X^{-1})p_X(Y)X^{-1}X^{-1}(XY^{-1}X^{-1})X^{-1}Y^{-1}X^{-1} = X^2 Y^{-1}X^{-1}.$$  

The same calculation shows $F_{P_0}(Y_{D_2}(\omega_H,d_1)) = X^2 Y^{-1}X^{-1}$ by the assumptions on $\omega_H,d_1$ in Definition 3.11. But then, since $p = 1$ in this case, we have

$$F_{P_0}(Y_{D_2}(\omega_H,d_1-1)p_X Y_{D_2}(\omega_H,d_1)) = (X^2 Y^{-1}X^{-1})(X^{-1})p_X(Y)X^{-1}(X^{-1})p_X(Y)X^{-1}X^{-1}(XY^{-1}X^{-1})X^{-1}Y^{-1}X^{-1} = X(X^{-1})d_1^{-1}(X^{-1})d_1^{-1}X^{-1},$$

which is exactly $X Y_{D_2}'(\omega_{V',d_1-1})$.

When $h_{d_1-1} \in \text{supp}(\omega_H)$, we have $Y_{D_2}(\omega_H,d_1-1) = p_{1,\omega(h_{d_1-1})}(XY^{-1}X^{-1})X^{-1}$ so that

$$F_{P_0}(Y_{D_2}(\omega_H,d_1-1)) = (P_0(Y)X^{-1})\omega(h_{d_1-1})^{-1}(X^{-1})d_1^{-1}-(\omega(h_{d_1-1})^{-1}p_{1,\omega(h_{d_1-1})}(X^{-1})d_1^{-1}-(\omega(h_{d_1-1})^{-1}X^{-1}X^{-1}.$$  

We saw above that $F_{P_0}(Y_{D_2}(\omega_H,d_1)) = X^2 Y^{-1}X^{-1}$ and so

$$F_{P_0}(Y_{D_2}(\omega_H,d_1-1)p_X Y_{D_2}(\omega_H,d_1)) = (P_0(Y)X^{-1})\omega(h_{d_1-1})^{-1}(X^{-1})d_1^{-1}-(\omega(h_{d_1-1})^{-1}p_{1,\omega(h_{d_1-1})}(X^{-1})d_1^{-1}-(\omega(h_{d_1-1})^{-1}X^{-1}X^{-1},$$

which is exactly $X Y_{D_2}'(\omega_{V',d_1-1})$. The claim then follows by induction from Lemma 4.6.

(b) Suppose there exists a vertical grading $\omega^*_V : V_m \to [0,d_2]$ of $D_m$ so that $(\omega_H, \omega^*_V)$ is piecewise compatible, but not compatible. By Theorem 3.20, there must exist a blocking edge $h_i$ for $\omega_H$. Set

$$d = |\text{supp}(\omega_H) \cap h_i v_{u_{m-1,2}}| \quad \text{and} \quad t = |\text{supp}(\omega^*_V) \cap h_i v_{u_{m-1,2}}|.$$  

By Proposition 3.10 and Proposition 3.16, $(\Omega_m, \omega^*_V, \varphi^*_m \omega_H)$ is a piecewise compatible grading of $D_{m+1}$ which is not compatible. Let $D(v_{u_{m-2,2}}' \varphi^*_m \omega_H) = h_j \varphi^*_m v_{u_{m-2,2}}$ and observe that $ht(h_j) = i - 1$ by definition of $\Omega_m$. By Proposition 3.18, Lemma 3.7, and Corollary 3.23, we have

$$|\text{supp}(\Omega_m \omega^*_V) \cap h_j \varphi^*_m v_{u_{m-2,1}}| = |\text{rhsh}(\varphi^*_m \omega_H) \cap h_j \varphi^*_m v_{u_{m-2,1}}| = |\text{rhsh}(\omega_H) \cap h_i v_{u_{m-1,2}}| = |\text{supp}(\omega^*_V) \cap h_i v_{u_{m-1,2}}|.$$  

Moreover, we have

$$|\text{supp}(\varphi^*_m \omega_H) \cap h_j \varphi^*_m v_{u_{m-2,1}}| = u_{m,1} - i + 1 - |\text{supp}(\omega_H) \cap h_i v_{u_{m-1,2}}| + \delta,$$

where $\delta = 0$ if $\omega_H(h_i-1) = d_1$ and $\delta = 1$ otherwise. If then follows from the definitions of $\varphi^*_m$ and $\Omega_m$ that the coefficients $p_2$ agree in Lemma 4.7 and Lemma 4.8.
Using the notation of Lemma 4.4 and Lemma 4.7, we have
\[ Y_{D_m}(\omega_H) = Y_{D_m}^{pc}(\omega_H) - Y_{D_m}^{nc}(\omega_H). \]

By induction we have \( F_{P_k}(Y_{D_{m-1}}(\omega_{H,r})) = Y_{D_{m-1}}(\phi_{m-1}^*(\omega_{H,r})) \) for \( 1 \leq r \leq d_m - d_0 \), and \( F_{P_k}(Y_{D_{m-1}}(\chi_H)) = Y_{D_{m-1}}^T(\chi_V) \). It follows that
\[ F_{P_k}(Y_{D_{m+1}}^{nc}(\omega_H)) = Y_{D_{m+1}}^{nc}(\phi_{m}^*(\omega_H)) \quad \text{and} \quad F_{P_k}(Y_{D_{m+1}}^{nc}(\omega_H)) = Y_{D_{m+1}}^{nc}(\phi_{m}^*(\omega_H)), \]
Since \( Y_{D_{m+1}}^{nc}(\phi_{m}^*(\omega_H)) = \phi_{m+1}^*(\omega_{H}) - Y_{D_{m+1}}^{nc}(\phi_{m}^*(\omega_H)) \), the result follows.

**Remark 4.9.** Our proof of the Main Theorem developed a combinatorial model for the analogue (2) of initial cluster mutations. It would be interesting and highly non-trivial to understand the direct combinatorial interpretation for the non-commutative exchange relations (3).

## 5. Specializations

In this section we consider the specialization to quantum generalized cluster variables. Assume \( v \in k \) is transcendental over \( Q \). Define the quantum torus algebra \( T := T_v = k[Z_1, Z_2 : Z_1Z_2 = vZ_2Z_1] \) and let \( F \) denote the skew-field of fractions of \( T \). It will be convenient to consider elements \( Z^a : v^{a_1}Z_1^{a_1}Z_2^{a_2} \) for \( a = (a_1, a_2) \in Z^2 \), these form a \( k \)-basis of \( F \).

Recall the notation (1) for the polynomials \( P_k, k \in Z \). Consider quantum generalized cluster variables \( Z_k^{(\alpha)} \in F, \alpha, k \in Z \), defined recursively by
\[ Z_1^{(\alpha)} = Z_1, \quad Z_2^{(\alpha)} = Z_2, \quad Z_k^{(\alpha)}Z_{k+1}^{(\alpha)} = P_{\alpha+k}(vZ_k^{(\alpha)}). \]

Observe that equation (20) immediately implies \( Z_k^{(\alpha)}Z_{k+1}^{(\alpha)} = v^2Z_{k+1}^{(\alpha)}Z_k^{(\alpha)} \) for all \( \alpha, k \in Z \).

For a fixed \( \alpha \in Z \), the quantum generalized cluster algebra \( A_k^{(\alpha)}(P_1, P_2) \subset F \) is the \( k \)-subalgebra generated by the \( Z_k^{(\alpha)}, k \in Z \). Although they are defined as elements of \( F \), the quantum generalized cluster variables actually live in \( T \). We give a direct proof here, however the combinatorial construction below provides an alternate proof. See [1] for a proof of this result in the special case when \( P_1 = T_1 \) and \( P_2 = T_2 \).

**Theorem 5.1.** Each quantum generalized cluster variable \( Z_k^{(\alpha)} \) is an element of \( T \subset F \).

**Proof.** Consider the monomial \( v^{d_{\alpha+k}}Z_{k-1}^{(\alpha)}(Z_{k+2}^{(\alpha)})^{d_{\alpha+k}}. \) Expanding \( Z_{k-1} \) in terms of \( Z_k^{(\alpha)} \) and \( Z_{k+1}^{(\alpha)} \) using equation (20) gives \( v^{d_{\alpha+k}}Z_{k-1}^{(\alpha)}(Z_{k+2}^{(\alpha)})^{d_{\alpha+k}} \) as
\[ v^{d_{\alpha+k}}P_{\alpha+k}(vZ_k^{(\alpha)})(Z_{k+2}^{(\alpha)})^{d_{\alpha+k}} = v^{-d_{\alpha+k}}P_{\alpha+k}(vZ_k^{(\alpha)})(Z_{k+2}^{(\alpha)})^{d_{\alpha+k}}(Z_{k+1}^{(\alpha)})^{-1} \]
\[ = \sum_{i=0}^{d_{\alpha+k}}P_{\alpha+k,i}v^{-d_{\alpha+k+i}}[(Z_k^{(\alpha)})^i(Z_{k+2}^{(\alpha)})^i - 1](Z_{k+2}^{(\alpha)})^{d_{\alpha+k}-i}(Z_{k+1}^{(\alpha)})^{-1} \]
\[ + P_{\alpha+k+2}(v^{-1}Z_{k+2}^{(\alpha)})(Z_{k+1}^{(\alpha)})^{-1} \]
\[ = \sum_{i=0}^{d_{\alpha+k}}P_{\alpha+k,i}v^{d_{\alpha+k-i}}[(Z_k^{(\alpha)})^i(Z_{k+2}^{(\alpha)})^i - 1](Z_{k+1}^{(\alpha)})^{-1}(Z_{k+2}^{(\alpha)})^{d_{\alpha+k-i}} \]
\[ + (Z_{k+1}^{(\alpha)})^{-1}P_{\alpha+k+2}(vZ_{k+2}^{(\alpha)}). \]
But for $0 \leq i \leq d_{\alpha}$, the term $(Z_k^{(\alpha)})^i(Z_{k+1}^{(\alpha)})^{i-1}$ above is a polynomial in $Z_{k+1}^{(\alpha)}$ with no constant term and so $[(Z_k^{(\alpha)})^i(Z_{k+1}^{(\alpha)})^{i-1}]$ is a polynomial in $Z_{k+1}^{(\alpha)}$. Thus we may solve for $Z_{k+1}^{(\alpha)} = (Z_{k+1}^{(\alpha)})^{-1}P_{\alpha+k+2}(vZ_{k+2}^{(\alpha)})$ above and see that this generalized cluster variable can be written as a polynomial in $k[Z_{k-1}^{(\alpha)}, Z_{k}^{(\alpha)}, Z_{k+1}^{(\alpha)}, Z_{k+2}^{(\alpha)}]$. A similar calculation shows $Z_{k-2}^{(\alpha)} \in k[Z_{k-1}^{(\alpha)}, Z_{k}^{(\alpha)}, Z_{k+1}^{(\alpha)}, Z_{k+2}^{(\alpha)}]$. Then by induction we see $Z_k^{(\alpha)} \subset k[Z_0^{(\alpha)}, Z_1^{(\alpha)}, Z_2^{(\alpha)}, Z_3^{(\alpha)}] \subset T$ for all $\alpha, k \in \mathbb{Z}$.

\begin{remark}
5.2
\end{remark}

The following specialization result will provide a combinatorial construction of the cluster variable can be written as a polynomial in $\mathbb{Z}$.

Theorem 5.3. For $m, \alpha \in \mathbb{Z}$, we have $\pi_v(X_m^{(\alpha+1)}) = vZ_m^{(\alpha+1)}$.

\begin{proof}
We work by induction on $m$. Since $X_0^{(\alpha)} = X$ and $X_1^{(\alpha)} = QY$ for all $\alpha \in \mathbb{Z}$, the cases $m = 0, 1$ follow immediately from equation (21).

For any nonzero polynomial $P \in k[z]$, define a $k$-linear automorphism $\mu_P : F \to F$ given by $\mu_P(Z_1) = Z_2$ and $\mu_P(Z_2) = Z_1P(vZ_1)$. These satisfy the functional identities $\pi_v \circ F \circ \pi_v = \mu_P \circ \pi_v$. Note that $\mu_P^{-1}(Z_1) = P(vZ_1)Z_1^{-1}$ and $\mu_P^{-1}(Z_2) = Z_1$ so that $\pi_v \circ F^{-1} = \mu_P^{-1} \circ \pi_v$.

Moreover, observe that $\mu_{P_{\alpha+2}}(Z_2) = Z_{3}^{(\alpha)}$ and $\mu_{P_{\alpha+1}}^{-1}(Z_1) = Z_{0}^{(\alpha)}$ for $\alpha \in \mathbb{Z}$. By the symmetry of the exchange relations (20), these imply $\mu_{P_{\alpha+2}}(Z_{m}^{(\alpha+1)}) = Z_{m+1}^{(\alpha)}$ and $\mu_{P_{\alpha+1}}^{-1}(Z_{m+1}^{(\alpha-1)}) = Z_{m}^{(\alpha)}$ for any $\alpha, m \in \mathbb{Z}$. Indeed, by induction on $m \geq 3$ we have

$Z_{m+1}^{(\alpha)} = (Z_{m}^{(\alpha)})^{-1}P_{\alpha+m}(vZ_{m}) = \mu_{P_{\alpha+2}}^{-1}(Z_{m-2}^{(\alpha)})^{-1}P_{\alpha+m}(vZ_{m})$

Similarly, by induction on $m \leq -2$ we have

$Z_{m+1}^{(\alpha)} = (Z_{m}^{(\alpha)})^{-1}P_{\alpha+m}(vZ_{m}) = \mu_{P_{\alpha+1}}^{-1}(Z_{m+2}^{(\alpha)})^{-1}P_{\alpha+m}(vZ_{m})$

Thus, by induction on $m \geq 1$ we see

$\pi_v(X_{m}^{(\alpha+1)}) = \pi_v(F_{P_{\alpha+2}}(X_{m}^{(\alpha+2)})) = \mu_{P_{\alpha+2}}^{-1}(\pi_v(X_{m}^{(\alpha+2)})) = \mu_{P_{\alpha+2}}^{-1}(vZ_m^{(\alpha+1)})$

\end{proof}
and by induction on \(m \leq -1\) we see
\[
\pi_v \left( X_m^{(a+1)} \right) = \pi_v \left( F_{n+1}^{-1} \left( X_m^{(a)} \right) \right) = \mu_{F_{n+1}}^{-1} \left( \pi_v \left( X_{m+1}^{(a)} \right) \right) = \mu_{F_{n+1}}^{-1} \left( v Z_m^{(a+1)} \right) = v Z_m^{(a)}.
\]

Applying the quantum specialization \(\pi_v\) to Theorem 1.3, Theorem 5.3 gives the following combinatorial construction of the quantum generalized cluster variables \(Z_m^{(a)}\). For notational convenience, we restrict to the quantum generalized cluster variables \(Z_m := Z_m^{(3)}\).

**Corollary 5.4.**

1. For \(m \geq 3\), the quantum generalized cluster variable \(Z_m\) is computed as follows:

   \[
   Z_m = \sum_{\omega \in D_{m-2} \cap \mathbb{Z}_{\geq 0}} p_\omega v^{1-u_{m-2,1} - u_{m-3,2} + \gamma_\omega + \beta_\omega} Z(-u_{m-2,1} + |\omega|_H, -u_{m-3,2} + |\omega|_V),
   \]

   where
   - the sum ranges over \((d_1, d_2)\)-bounded compatible gradings \(\omega\) of \(D_{m-2}\);
   - \(p_\omega = \prod_{l=1}^{m-2,1} p_{1, \omega(l)} \prod_{l=1}^{m-3,2} p_{2, \omega(l)} \prod_{l=1}^{m-3,2} p_{2, \omega(l)}(v_i)\);
   - \(\gamma_\omega = \sum_{e < e' \in E_{m-2}} \gamma_\omega(e, e')\) for

2. For \(m \leq 0\), the quantum generalized cluster variable \(Z_m\) is computed as follows:

   \[
   Z_m = \sum_{\omega \in D'_{m+1} \cap \mathbb{Z}_{\geq 0}} p_\omega' v^{-1 + u'_{-m+1,1} + u'_{-m,2} + \gamma'_\omega + \beta'_\omega} Z(-u'_{-m,2} + |\omega|_H', -u'_{-m+1,1} + |\omega|_V'),
   \]

   where
   - the sum ranges over \((d_2, d_1)\)-bounded compatible gradings \(\omega\) of \(D'_{m+1}\);
   - \(p'_\omega = \prod_{l=1}^{m+1,1} p_{2, \omega(l)} \prod_{l=1}^{m+2,2} p_{1, \omega(l)}(v_i')\);
   - \(\gamma'_\omega = \sum_{e < e' \in E'_{m+1}} \gamma'_\omega(e, e')\) for

\[
\gamma'_\omega(e, e') = \begin{cases} 0 & \text{if } e \in V'_{-m+1} \cap \text{supp}(\omega|_V') \text{ or } e' \in H'_{m+1} \cap \text{supp}(\omega|_H'); \\ -2\omega(e)\omega(e') & \text{if } e \in \text{supp}(\omega|_V') \text{ and } e' \in \text{supp}(\omega|_H'); \\ 2\omega(e) & \text{if } e \in \text{supp}(\omega|_V') \text{ and } e' \in V'_{m+1}; \\ 2\omega(e') & \text{if } e \in H'_{m+1} \text{ and } e' \in \text{supp}(\omega|_H'); \\ -2 & \text{if } e \in H'_{m+1} \text{ and } e' \in V'_{m+1}; \\ \end{cases}
\]
\[ \beta'_\omega(e, e') = \sum_{e < e' \in E_{-m+1}} \beta'_\omega(e, e') \]

\[ = \left\{ \begin{array}{ll}
\omega(e) \omega(e') + 1 & \text{if } e \in H'_{-m+1} \text{ and } e' \in V'_{-m+1} \text{ or } e \in V'_{-m+1} \text{ and } e' \in H'_{-m+1}; \\
-(\omega(e) + \omega(e')) & \text{if } e, e' \in H'_{-m+1} \text{ or } e, e' \in V'_{-m+1}.
\end{array} \right. \]

**Proof.** We prove part 1, the proof of part 2 is essentially the same where the roles of \( X \) and \( Y \) are interchanged in equation (4).

First note that we have \( X_{m-1} = QY_{m-2} \) so that \( vZ_m = \pi_v(X_{m-1}) = \nu^2 \pi_v(Y_{m-2}) \), in particular this accounts for the 1 appearing in the exponent of \( v \) in equation (22). By Theorem 1.3, we may compute \( Y_{m-2} \) by considering compatible gradings on the maximal Dyck path \( D_{m-2} \) and thus \( Z_m \) can be computed by applying the quantum projection \( \pi_v \) to equation (5). Then the exponents of \( Z_1 \) and \( Z_2 \) in equation (22) are immediate from Lemma 3.2. The coefficient \( p_{v,j} \) also follows directly from the definition of the non-commutative edge weights in equation (4), so for the remainder of the proof we assume \( p_{i,j} = 1 \) for all \( i \) and \( j \).

Note that

\[ Z^{(a_1, a_2)}(b_1, b_2) = v^{a_1 b_2 - a_2 b_1} Z^{(a_1 + b_1, a_2 + b_2)} \]

for \( a_i, b_i \in \mathbb{Z}, i = 1, 2 \). The rest of the exponent of \( v \) in equation (22) can be seen as follows:

(a) for an edge \( e \in E_{m-2} \) we have

\[ \pi_v(\text{wt}_\omega(e)) = \left\{ \begin{array}{ll}
\pi_v(Y^{\omega(e)}X^{-1}) & \text{if } e \in H_{m-2} \\
\pi_v(X^{\omega(e)+1}Y^{-1}X^{-1}) & \text{if } e \in V_{m-2}
\end{array} \right. \]

\[ = \left\{ \begin{array}{ll}
u^{-\omega(e)-1} Z_2^{-1} Z_1^{-1} X^{-1} & \text{if } e \in H_{m-2} \\
\nu^{\omega(e)+1} Z_1 Z^{-1} Z_1^{-1} & \text{if } e \in V_{m-2}
\end{array} \right. \]

\[ = \left\{ \begin{array}{ll}
u^{-1} Z^{(-1, \omega(e))} & \text{if } e \in H_{m-2}; \\
\nu^{-1} Z^{(\omega(e), -1)} & \text{if } e \in V_{m-2};
\end{array} \right. \]

The \( \nu^{-1} \) in each possibility above accounts for the terms \( -u_{m,1} \) and \( -u_{m-1,2} \) in equation (22).

(b) for \( e, e' \in E_{m-2} \), the quantity \( \gamma_\omega(e, e') \) from equation (23) records the power of \( v \) which appears when commuting powers of \( Z_2 \) appearing in \( \pi_v(\text{wt}_\omega(e)) \) past powers of \( Z_1 \) appearing in \( \pi_v(\text{wt}_\omega(e')) \);

(c) for \( e, e' \in E_{m-2} \), the quantity \( \beta_\omega(e, e') \) from equation (24) records the power of \( v \) so that

\[ \pi_v(\text{wt}_\omega(e)) \pi_v(\text{wt}_\omega(e')) = v^{\gamma_\omega(e, e') + \beta_\omega(e, e') - 1} Z^{(a_1, a_2)} \]

for appropriate \( a_1, a_2 \in \mathbb{Z} \) depending on \( e, e' \in E_{m-2} \) (the \( -2 \) here accounts for part (a) above).

Since we have \( Z_m = v \pi_v(Y_{D_{m-2}}) \), the result follows by combining the observations above. \( \Box \)

Let \( k = \mathbb{Q}(v) \) for an indeterminate \( v \). When \( p_{i,j} = 0 \) for \( i = 1, 2 \) and \( 1 \leq j \leq d_i - 1 \), the expansions of the quantum generalized cluster variables as elements of \( T \) have been computed [11] using the representation theory of valued quivers as follows. In this case, we drop the adjective “generalized” and refer to the \( Z_k^{(\alpha)} \) simply as quantum cluster variables.
Let $d = \gcd(d_1, d_2)$. Consider the quiver $\Lambda$ with vertices $\Lambda_0 = \{1, 2\}$ with $d$ arrows $a_j : 2 \to 1$, $1 \leq j \leq d$. Write $\mathbb{F}_q$ for the finite field with $q$ elements and fix an algebraic closure $\overline{\mathbb{F}}_q$ of $\mathbb{F}_q$. Let $F_{q^d_1}, F_{q^d_2}, F_{q^d} \subset \overline{\mathbb{F}}_q$ denote the extension fields of $\mathbb{F}_q$ of degree $d_1, d_2, d$, respectively. Note that $F_{q^d_1}$ and $F_{q^d_2}$ are naturally identified as vector spaces over $F_{q^d}$.

A valued representation $V = (V_1, V_2, V_3)$ of $\Lambda$ consists of $F_{q^d_1}$-vector spaces $V_i$ for $i = 1, 2$ and $F_{q^d}$-linear maps $V_{a_j} : V_2 \to V_1$ for $1 \leq j \leq d$. For representations $V = (V_1, V_2, V_3)$ and $W = (W_1, W_2, W_3)$, a morphism $\theta : V \to W$ consists of $F_{q^d}$-linear maps $\theta_j : V_i \to W_i$ for $i = 1, 2$ such that the following diagram commutes for $1 \leq j \leq d$:

$$
\begin{array}{ccc}
V_1 & \xrightarrow{\theta_j} & V_2 \\
\downarrow{a_1} & & \downarrow{a_2} \\
W_1 & \xrightarrow{W_{a_j}} & W_2
\end{array}
$$

Thus the finite-dimensioned valued representations of $\Lambda$ form a category $\text{rep}(\Lambda)$. In fact, this category is well-known to be abelian, $\mathbb{F}_q$-linear, and Krull–Schmidt. Write $\mathcal{K}(\Lambda)$ for the Grothendieck group of the category $\text{rep}(\Lambda)$, then $\mathcal{K}(\Lambda) \cong \mathbb{Z}^2$ where the class $[V] = (\dim_{q^d_1} V_1, \dim_{q^d} V_2)$ of a valued representation $V$ of $\Lambda$ gives its dimension vector. Define a $\mathbb{Z}$-bilinear pairing $\langle \cdot, \cdot \rangle : \mathcal{K}(\Lambda) \times \mathcal{K}(\Lambda) \to \mathbb{Z}$ on the natural basis $\alpha_1 = (1, 0)$ and $\alpha_2 = (0, 1)$ by

$$
\langle \alpha_i, \alpha_i \rangle = d_i, \quad \langle \alpha_1, \alpha_2 \rangle = 0, \quad \langle \alpha_2, \alpha_1 \rangle = -d_1 d_2.
$$

For a valued representation $V$ of $\Lambda$ and a dimension vector $e = (e_1, e_2) \in \mathcal{K}(\Lambda)$, write $\text{Gr}_e(V)$ for the Grassmannian of subrepresentations of $V$ with dimension vector $e$:

$$
\text{Gr}_e(V) = \{ E \subset V : [E] = e \}.
$$

The quiver Grassmannian $\text{Gr}_e(V)$ naturally embeds as a closed subvariety in the product $\text{Gr}_{e_1}(V_1) \times \text{Gr}_{e_2}(V_2)$, in particular it is a projective variety. When $V$ is rigid, i.e. $\text{Ext}^1(V, V) = 0$, Caldero and Reineke have shown [3] that $\text{Gr}_e(V)$ is smooth.

Since the field $\mathbb{F}_q$ is finite, each Grassmannian $\text{Gr}_e(V)$ is a finite set. For $V$ rigid, a result of [13] shows that the number of points in $\text{Gr}_e(V)$ can be computed by evaluating a polynomial $P_{e, V}(t) \in \mathbb{Z}[t]$ at $q = |F_q|$. Note that since $V$ is rigid, it is uniquely determined up to isomorphism by its dimension vector $[V] \in \mathcal{K}(\Lambda)$.

**Theorem 5.5** ([13, Corollary 1.2]). Let $V$ be a rigid valued representations of $\Lambda$. For each dimension vector $e \in \mathcal{K}(\Lambda)$, there exists a polynomial $P_{e, V}(t) \in \mathbb{Z}[t]$ depending only on the dimension vector of $V$ so that

$$
|\text{Gr}_e(V)| = P_{e, V}(q).
$$

It was conjectured in [13] that for a rigid representation $V$ the counting polynomials $P_{e, V}(t)$ have positive coefficients and are unimodal. Corollary 5.7 proves this positivity conjecture by giving a positive combinatorial construction of these counting polynomials. It remains an interesting open question to see how this combinatorics can be used to establish unimodality.

Define the quantum cluster character of a rigid valued representation $V$ of $\Lambda$ by

$$
Z_V = \sum_{e \in \mathcal{K}(\Lambda)} v^{\langle e, v - e \rangle} P_{e, V}(t^2) Z^{(v_1 + d_2 v_2, -v_2 + d_1 (v_1 - e_1))},
$$

where $[V] = v = (v_1, v_2)$ and $e = (e_1, e_2)$. Write $P_m$ (resp. $I_m$, $m \geq 1$, for the preprojective (resp. preinjective) valued representations of $\Lambda$ (definitions can be found in [11]) where it is shown that $[P_m] = a_m$ and $[I_m] = a'_m$). Then the Laurent expansions...
of the non-initial quantum cluster variables $Z_m$, $m \in \mathbb{Z} \setminus \{1, 2\}$, can be computed as follows.

**Theorem 5.6 ([11]).** Assume the intermediate exchange coefficients $p_{i,j} = 0$ for $i = 1, 2$ and $1 \leq j \leq d_i - 1$. Then the following hold:

(a) for $m \geq 3$, the quantum cluster variable $Z_m$ is equal to $Z_{P_m - 2}$;
(b) for $m \leq 0$, the quantum cluster variable $Z_m$ is equal to $Z_{I_{m+1}}$.

Combining Corollary 5.4 with Theorem 5.6, we obtain a combinatorial construction of the counting polynomials for Grassmannians of subrepresentations in rigid valued quiver representations.

**Corollary 5.7.** For $m \geq 1$, the counting polynomials $P_{e,P_m}(t)$ and $P_{e,I_m}(t)$ are given by

\[ P_{e,P_m}(t) = \sum_{\omega : E_m \to \mathbb{Z}_{\geq 0}} t^{\gamma_{\omega}}, \]

where

- the sum ranges over $(d_1, d_2)$-bounded compatible gradings $\omega$ of $D_m$ such that $\omega(H_m) \subset \{0, d_1\}$, $\omega(V_m) \subset \{0, d_2\}$, $|\text{supp}(\omega_H)| = u_{m,1} - e_1$, and $|\text{supp}(\omega_V)| = e_2$;
- $\gamma_{\omega} = \sum_{e < e' \in E_m} \gamma_{\omega}(e, e')$ for

\[ \gamma_{\omega}(e, e') = \begin{cases} -d_1d_2 & \text{if } e \in \text{supp}(\omega_H) \text{ and } e' \in \text{supp}(\omega_V); \\
d_1 & \text{if } e \in \text{supp}(\omega_H) \text{ and } e' \in H_m \setminus \text{supp}(\omega_H); \\
d_2 & \text{if } e \in V_m \setminus \text{supp}(\omega_V) \text{ and } e' \in \text{supp}(\omega_V); \\
0 & \text{otherwise}; \end{cases} \]

and

\[ P_{e,I_m}(t) = \sum_{\omega : E_m' \to \mathbb{Z}_{\geq 0}} t^{\gamma_{\omega}}, \]

where

- the sum ranges over $(d_2, d_1)$-bounded compatible gradings $\omega$ of $D_m'$ such that $\omega(H_m') \subset \{0, d_2\}$, $\omega(V_m') \subset \{0, d_1\}$, $|\text{supp}(\omega_H')| = u_{m,1} - e_1$, and $|\text{supp}(\omega_V')| = e_2$;
- $\gamma_{\omega} = \sum_{e < e' \in E_m'} \gamma_{\omega}(e, e')$ for

\[ \gamma_{\omega}(e, e') = \begin{cases} -d_1d_2 & \text{if } e \in \text{supp}(\omega_V') \text{ and } e' \in \text{supp}(\omega_H'); \\
d_1 & \text{if } e \in \text{supp}(\omega_V') \text{ and } e' \in V_m' \setminus \text{supp}(\omega_H'); \\
d_2 & \text{if } e \in H_m' \setminus \text{supp}(\omega_H') \text{ and } e' \in \text{supp}(\omega_V'); \\
0 & \text{otherwise}. \end{cases} \]

**Proof.** We prove equation (27), the proof of equation (29) is essentially the same.

By Corollary 5.4 and Theorem 5.6, we have

\[ P_{e,P_m}(e^2) = \sum_{\omega : E_m \to \mathbb{Z}_{\geq 0}} u^{-\langle e, a_m - e \rangle + 1 - u_{m,1} - u_{m-1,2} + \gamma_{\omega} + \beta_{\omega}}, \]

where the sum ranges over all $(d_1, d_2)$-bounded compatible gradings of $D_m$ with $\omega(H_m) \subset \{0, d_1\}$, $\omega(V_m) \subset \{0, d_2\}$, $|\text{supp}(\omega_H)| = u_{m,1} - e_1$, and $|\text{supp}(\omega_V)| = e_2$.

But observe that

\[ \langle e, a_m - e \rangle = d_1e_1(u_{m,1} - e_1) + d_2e_2(u_{m-1,2} - e_2) - d_1d_2e_2(u_{m,1} - e_1) \]

*Algebraic Combinatorics, Vol. 2 #6 (2019)*
and under the assumptions on $\omega$ we have
\[ \beta_\omega = d_1 d_2 e_2 (u_{m,1} - e_1) + u_{m,1} u_{m-1,2} - d_1 e_1 (u_{m,1} - e_1) - 2 d_1 \left( \frac{u_{m,1} - e_1}{2} \right) - d_2 e_2 (u_{m-1,2} - e_2) - 2 d_2 \left( \frac{e_2}{2} \right). \]
Canceling like terms gives
\[ P_{e,P_m}(v^2) = \sum_{\omega: E_m \to \mathbb{Z}_{\geq 0}} v^{(u_{m,1}-1)(u_{m-1,2}-1) - 2 d_1 \left( \frac{u_{m,1} - e_1}{2} \right) - 2 d_2 \left( \frac{e_2}{2} \right) + \gamma_\omega}. \]
When $|\text{supp}(\omega_H)| = 0$ and $|\text{supp}(\omega_V)| = 0$, we have $\gamma_\omega = -2 |\{ e, e' \in E_m : e < e', e \in V_m, e' \in H_m \}|$. But these assumptions imply $e = (u_{m,1}, 0)$ so that $P_{e,P_m}(t) = 1$ and thus
\[ (u_{m,1} - 1)(u_{m-1,2} - 1) = 2 |\{ e, e' \in E_m : e < e', e \in V_m, e' \in H_m \}|. \]
In particular, the case $e \in V_m$ and $e' \in H_m$ can be ignored when computing $\gamma_\omega$ if we omit the term $(u_{m,1} - 1)(u_{m-1,2} - 1)$ from the exponent of $v$. Since $|\text{supp}(\omega_H)| = u_{m,1} - e_1$ and $|\text{supp}(\omega_V)| = e_2$, the cases $e, e' \in \text{supp}(\omega_H)$ and $e, e' \in \text{supp}(\omega_V)$ can also be ignored giving
\[ P_{e,P_m}(v^2) = \sum_{\omega: E_m \to \mathbb{Z}_{\geq 0}} v^{2 \gamma_\omega}. \]
This gives the result since $v$ was an indeterminate.

\begin{remark}
The exponents in equation (27) are not manifestly positive, however equation (28) giving the exponents can be refined as follows. Consider $e \in \text{supp}(\omega_H)$ and $e' \in \text{supp}(\omega_V)$ with $e < e'$ which contributes a term $-d_1 d_2$ in equation (28). The $d_2$ horizontal edges preceding $e'$ cannot be in the support of $\omega_H$ by compatibility, moreover each such horizontal edge $h$ satisfies $e < h$. In particular, these pairs $e < h$ together contribute a term $d_1 d_2$ in equation (28). Thus the negative contribution to $\gamma_\omega$ will always cancel and equation (27) indeed gives $P_{e,P_m}(t)$ as a polynomial in $t$.
