Abstract

Insa and Pauer presented a basic theory of Gröbner basis for differential operators with coefficients in a commutative ring in 1998, and a criterion was proposed to determine if a set of differential operators is a Gröbner basis. In this paper, we will give a new criterion such that Insa and Pauer’s criterion could be concluded as a special case and one could compute the Gröbner basis more efficiently by this new criterion.

Keywords:
Gröbner basis, rings of differential operators.

1. Introduction

Many investigations have been done on Gröbner basis in rings of differential operators (Adams and Loustaunau, 1994; Björk, 1979; Galligo, 1985; Mora, 1986; Oaku and Shimoyama, 1994), but the coefficients are in fields (of rational functions), rings of power series, or rings of polynomials over a field. For example, Mora gave an introduction to commutative and non-commutative Gröbner bases, which includes Gröbner bases for Weyl algebra (Mora, 1994). As in Insa and Pauer’s paper, the rings of coefficients in this paper are general commutative rings, which is the main difference from other existing works.

In Insa and Pauer’s paper (Insa and Pauer, 1998), the results of Buchberger on Gröbner basis in polynomial rings have been extended to the theory of Gröbner basis for differential operators. A criterion was presented to determine if a set of differential operators is a Gröbner basis, and a basic method for computing the Gröbner basis was also proposed. Pauer generalized the theory to a class of rings which includes rings of differential operators with coefficients in noetherian rings (Pauer, 2007).

For computing the Gröbner basis of a set of differential operators, instead of computing the generators of the syzygy module generated by their initials, Insa and Pauer’s method needs to compute the generators of many syzygy modules generated by their leading coefficients. Thus, Insa and Pauer’s method leads to many unnecessary computations. In order to improve the efficiency, Zhou and Winkler proposed some techniques to reduce the computations on the syzygies (Zhou and Winkler, 2007).

In this paper, a new criterion is proposed for computing Gröbner basis in the ring of differential operators with coefficients in a general commutative ring.
The new criterion bases on the following simple fact: Let \( f, g \) be two differential operators, then
\[
fg = gf + h,
\]
where \( fg \) and \( gf \) have the same degree, but \( h \) has less degree than \( fg \) or \( gf \). The above equation implies that even though the multiplication in the rings of differential operators is not commutative, the products \( fg \) and \( gf \) still have the same initial. According to this fact, it suffices to consider the generators of the syzygy module in a commutative ring which is deduced from the ring of differential operators. With these generators, a new criterion is proposed to determine if a set of differential operators is a Gröbner basis. This new result generalizes the Insa and Pauer’s original theorem such that their theorem can be concluded as a special case of the new theorem. Furthermore, the results of this paper can extend naturally to the rings that preserve the same fact.

Then the proposed criterion also leads to an efficient method for computing Gröbner bases in the rings of differential operators. This new method considers fewer s-polynomials than those in Insa and Pauer’s method as well as Zhou and Winkler’s improved version. So it is not surprising that this new method will have better efficiency than others.

This paper is organized as follow. Section 2 includes some preliminaries of the Gröbner Basis in the rings of differential operators. The Insa and Pauer’s theorem comes in section 3. In section 4, the new criterion is presented in detail. And some algorithmic problems are discussed in section 5. The paper is concluded in section 6.

2. Gröbner Basis in Rings of Differential Operators

Let \( K \) be a field of characteristic zero, \( \mathbb{N} \) the set of non-negative integers, \( n \in \mathbb{N} \) a positive integer and \( K[X] := K[x_1, \ldots, x_n] \) (resp. \( K(X) := K(x_1, \ldots, x_n) \)) the ring of polynomials (resp. the field of rational functions) in \( n \) variables over \( K \). Let \( \frac{\partial}{\partial x_i} : K(X) \to K(X) \) be the partial derivative by \( x_i \) for \( 1 \leq i \leq n \).

Let \( \mathcal{R} \) be a noetherian \( K \)-subalgebra of \( K(X) \) which is stable by \( \frac{\partial}{\partial x_i} \) for \( 1 \leq i \leq n \), i.e. \( \frac{\partial}{\partial x_i}(r) \in \mathcal{R} \) for all \( r \in \mathcal{R} \). Important examples for \( \mathcal{R} \) are \( K[X], K(X) \) and \( K[X]_M := \{ f \in K(X) \mid f \in K[X], g \in M \} \) where \( M \) is a subset of \( K[X] \setminus \{0\} \) closed under multiplication.

Assume the linear equations over \( \mathcal{R} \) can be solved, i.e.

1. for all \( g \in \mathcal{R} \) and all finite subsets \( F \subset \mathcal{R} \), it is possible to decide whether \( g \) is an element of \( \mathcal{R}(F) \), and if yes, it is available to obtain a family \( (d_f)_{f \in F} \) in \( \mathcal{R} \) such that \( g = \sum_{f \in F} d_f f \);
2. for all finite subsets \( F \subset \mathcal{R} \), a finite system of generators of the \( \mathcal{R} \)-module

\[
\{ (s_f)_{f \in F} \mid \sum_{f \in F} s_f f = 0, s_f \in \mathcal{R} \}
\]

can be computed.

The partial differential operator \( D_i \) is defined as the restriction of \( \frac{\partial}{\partial x_i} \) to \( \mathcal{R} \) for \( 1 \leq i \leq n \). Let \( \mathcal{A} := \mathcal{R}[D] = \mathcal{R}[D_1, \ldots, D_n] \) be the \( \mathcal{R} \)-subalgebra of \( \text{End}_k(\mathcal{R}) \) generated by \( \text{id}_\mathcal{R} = 1 \).
and $D_1, \ldots, D_n$. Then the ring $\mathcal{A}$ is “a ring of differential operators with coefficients in $\mathcal{R}$”, while the elements of $\mathcal{A}$ are called “differential operators with coefficients in $\mathcal{R}$” [Insa and Pauer 1998]. It is well known that $\mathcal{A}$ is a left-noetherian associative $\mathcal{R}$-algebra, so the ideals in $\mathcal{A}$ always refer to the left-ideals of $\mathcal{A}$ in this paper.

$\mathcal{A}$ is a non-commutative $K$-algebra with fundamental relations:

$$x_ix_j = x_jx_i, \ D_iD_j = D_jD_i \text{ for } 1 \leq i, j \leq n,$$

and

$$D_ir - rD_i = D_i(r), \ r \in \mathcal{R}.$$

For a simple example, let $\mathcal{A} = (k[x_1, x_2])[D_1, D_2]$, then

$$x_1x_2 = x_2x_1, \ D_1D_2 = D_2D_1 \text{ and } D_1x_1x_2 - x_1x_2D_1 = D_1(x_1x_2) = x_2.$$

And for any $f \in \mathcal{A}$, $f$ can be written uniquely as a finite sum

$$f = \sum_{\alpha \in \mathbb{N}^n} r_\alpha D^\alpha, \ \text{where } r_\alpha \in \mathcal{R}.$$

Let $\prec$ be an admissible order on $\mathbb{N}^n$, i.e. a total order on $\mathbb{N}^n$ such that $0 \in \mathbb{N}^n$ is the smallest element and $\alpha \prec \beta$ implies $\alpha + \gamma \prec \beta + \gamma$ for all $\alpha, \beta, \gamma \in \mathbb{N}^n$. Then for a differential operator $0 \neq f = \sum_{\alpha \in \mathbb{N}^n} r_\alpha D^\alpha \in \mathcal{A}$, the degree, leading coefficient and initial are defined as:

$$\deg(f) := \max_{\prec} \{\alpha \mid r_\alpha \neq 0\} \in \mathbb{N}^n,$$

$$\lc(f) := r_{\deg(f)},$$

$$\init(f) := \lc(f)D^{\deg(f)}.$$

If $F$ is a subset of $\mathcal{A}$, define:

$$\deg(F) := \{\deg(f) \mid f \in F, f \neq 0\},$$

$$\init(F) := \{\init(f) \mid f \in F, f \neq 0\}.$$

It is easy to check $\mathcal{A}$ has the following properties. Let $f, g, h \in \mathcal{A}$:

**Associativity:**

$$(fg)h = f(gh).$$

**Distributivity:**

$$f(g + h) = fg + fh \text{ and } (f + g)h = fh + gh.$$

There is another property about $\mathcal{A}$ which will be used frequently in this paper. Let $\init(f) = r_fD^{\alpha_f}$ and $\init(g) = r_gD^{\alpha_g}$, $r_f, r_g \in \mathcal{R}$, then

$$\deg(fg) = \deg(f) + \deg(g), \ \lc(fg) = \lc(f)\lc(g) \text{ and } \init(fg) = r_fr_gD^{\alpha_f+\alpha_g}.$$
Definition 2.1. Let $J$ be an ideal in $A$ and $G$ a finite subset of $J \setminus \{0\}$. Then $G$ is a Gröbner basis of $J$ w.r.t. $\prec$ iff for all $f \in J$,

$$\text{lc}(f) \in \mathcal{R}(\text{lc}(g) \mid g \in G, \text{deg}(f) \in \text{deg}(g) + \mathbb{N}^n).$$

Example 2.2. If $J = A\langle f \rangle \subset A$ and $f \neq 0$, then $\{f\}$ is a Gröbner basis of $J$.

3. Insa and Pauer’s Theorem

In order to compute the Gröbner basis, a division (or reduction) in $A$ is necessary. In theory, there may exist various kinds of divisions in $A$. The following division is the one presented by Insa and Pauer in Insa and Pauer, 1998.

Proposition 3.1 (Division in $A$). Let $F$ be a finite subset of $A \setminus \{0\}$ and $g \in A$. Then there exist a differential operator $r \in A$ and a family $(h_f)_{f \in F}$ in $A$ such that:

(i). $g = \sum_{f \in F} h_f f + r$, ($r$ is “a remainder of $g$ after division by $F$”),
(ii). for all $f \in F$, $h_f f = 0$ or $\text{deg}(h_f f) \leq \text{deg}(g)$,
(iii). $r = 0$ or $\text{lc}(r) \notin \mathcal{R}(\text{lc}(f) \mid \text{deg}(r) \in \text{deg}(f) + \mathbb{N}^n)$.

This definition of division in $A$ is also used in the new theorem presented in the next section. Based on this division, a Gröbner basis in $A$ has the following property Insa and Pauer, 1998.

Proposition 3.2. Let $J$ be an ideal in $A$, $G$ a Gröbner basis of $J$ and $f \in A$. Then $f \in J$ iff a remainder of $f$ after division by $G$ is zero.

Then the next theorem proposed by Insa and Pauer provides a criterion for checking if a set of differential operators is a Gröbner basis.

Theorem 3.3 (Insa and Pauer’s theorem). Let $G$ be a finite subset of $A \setminus \{0\}$ and $J$ the ideal in $A$ generated by $G$. For $E \subset G$, let $S_E$ be a finite set of generators of the $\mathcal{R}$-module

$$\text{Syz}_{\mathcal{R}}(E) := \{(s_e)_{e \in E} \mid \sum_{e \in E} s_e \text{lc}(e) = 0\} \subset \mathcal{R}(\mathcal{R}^{|E|}).$$

Then the following assertions are equivalent:

(i). $G$ is a Gröbner basis of $J$.
(ii). For all $E \subset G$ and for all $(s_e)_{e \in E} \in S_E$, a remainder of

$$\text{SPoly}(E, (s_e)_{e \in E}) := \sum_{e \in E} s_e D^{m(E) - \text{deg}(e)} e$$

after division by $G$ is zero, where

$$m(E) := (\max_{e \in E} \text{deg}(e), \cdots, \max_{e \in E} \text{deg}(e)_n) \in \mathbb{N}^n.$$
According to this theorem, one is able to compute the Gr"obner basis of $A \langle F \rangle$ for any subset $F \subset A$. All needed to do is to check the remainder of $\sum_{e \in E} s_e D^{m(E) - \deg(e)} e$ after division by $F$ is zero or not for all $E \subset F$. If there does exist a remainder $r$ which is not zero, then expand $F$ to $F' := F \cup \{r\}$ and repeat the process for $F'$. The procedure terminates exactly when all the remainders are zero. The terminality of this algorithm can be proved in a similar way as the general Gr"obner basis algorithm.

During the above computing process, in order to seek non-zero remainders w.r.t. the subsets of $F$, one needs to compute the generators of $\text{Syz}(E)$ for all $E \subset F$, which is really expensive. In view of this, Zhou and Winkler proposed a trick to avoid some unnecessary computations ([Zhou and Winkler, 2007]). In their paper, they show that if the elements in $E$ have some special properties, then instead of computing the generators of $\text{Syz}(E)$, it only suffices to calculate the generators of $\text{Syz}(E')$ for some $E' \subset E$. Since the new theorem in the current paper generalizes Insa and Pauer’s theorem in a different way from Zhou and Winkler, the details of their method are omitted here. For interesting readers, please see ([Zhou and Winkler, 2007]).

4. The New Theorem for Gr"obner Basis in Rings of Differential Operators

The differential operator

$$\text{SPoly}(E, (s_e)_{e \in E}) = \sum_{e \in E} s_e D^{m(E) - \deg(e)} e$$

in (ii) of the Insa and Pauer’s theorem is denoted as a “generalized s-polynomial” w.r.t. the subset $E \subset G$ in ([Zhou and Winkler, 2007]), as it plays the same role as the general s-polynomials.

However, this generalized s-polynomial in Insa and Pauer’s theorem is constructed quite strangely, since it is not created by the syzygies of init($G$) in the traditional way but results from the set $S_E$, which is a set of generators of $\{(s_e)_{e \in E} \mid \sum_{e \in E} s_e \text{lc}(e) = 0\}$. With a further study, one will find the reason easily. That is, the syzygy of init($G$) is extremely difficult to define and even harder to compute, as $A$ is a non-commutative ring. This explains why Insa and Pauer concentrate on the syzygy of lc($E$) in $R$ instead.

At this point, it is natural to ask: do we really need the syzygy of init($G$)? The answer is NO!

By revisiting the proof of Insa and Pauer’s theorem carefully, in order to show $G$ is a Gr"obner basis, it suffices to consider the differential operators which are generated by $G$ and possibly have new initials. So all we need to do is to eliminate the present initials of $G$ and to try to create all possible new initials in $A \langle G \rangle$. Fortunately, the syzygy of init($G$) is not the only one that could do this job, since the ring $A$ has the Quasi-Commutativity.

With these considerations in mind, let discuss a commutative ring $B$ first which is deduced from the Quasi-Commutative ring $A$.

Let $B := R[Y] = R[y_1, \ldots, y_n]$, which is generated by $\text{id}_R = 1$ and $y_1, \ldots, y_n$. $B$ is a commutative $K$-algebra with fundamental relations:

$$x_i x_j = x_j x_i, \quad y_i y_j = y_j y_i \quad \text{and} \quad x_i y_j = y_j x_i \quad \text{for} \quad 1 \leq i, j \leq n.$$
For any \( f \in B \), \( f \) can also be written uniquely as a finite sum \( f = \sum_{\alpha} r_{\alpha} Y^\alpha \), where \( r_{\alpha} \in \mathbb{R} \). Similarly, the degree, leading coefficient and initial are defined as: \( \text{deg}(f) := \max_{\alpha} \{ \alpha \mid r_{\alpha} \neq 0 \} \in \mathbb{N} \), \( \text{lc}(f) := r_{\text{deg}(f)} \) and \( \text{init}(f) := Y^\text{deg}(f) \) respectively.

Since \( Y \) commute with \( X \) and the linear equations over \( \mathbb{R} \) are solvable, it is easy to check the linear equations over \( B \) can be solved as well, which means the generators of \( \text{Syz}_B(F) := \{ (s_f)_{f \in F} \mid \sum_{f \in F} s_f \text{init}(f) = 0, s_f \in B \} \) can be computed, where \( F \subset B \setminus \{0\} \).

With a little care, the only difference between \( B \) and \( A \) is that \( B \) is commutative and \( A \) is not. The following map bridges the two rings easily. Let \( \sigma \) be a map from \( B \) to \( A \) such that for any \( \sum_{\alpha} r_{\alpha} Y^\alpha \in B \) where \( r_{\alpha} \in \mathbb{R} \),

\[
\sigma(\sum_{\alpha} r_{\alpha} Y^\alpha) = \sum_{\alpha} r_{\alpha} D^\alpha \in A.
\]

By the definition of \( \sigma \), the following properties hold for all \( f, g \in B \):

\[
\begin{align*}
\text{deg}(f) &= \text{deg}(\sigma(f)), \\
\text{lc}(f) &= \text{lc}(\sigma(f)), \\
\sigma(\text{init}(f)) &= \text{init}(\sigma(f)), \\
\text{deg}(fg) &= \text{deg}(\sigma(fg)) = \text{deg}(\sigma(f)\sigma(g)), \\
\text{lc}(fg) &= \text{lc}(\sigma(fg)) = \text{lc}(\sigma(f)\sigma(g)), \\
\sigma(\text{init}(fg)) &= \text{init}(\sigma(fg)) = \text{init}(\sigma(f)\sigma(g)).
\end{align*}
\]

But remark that \( \sigma(fg) \neq \sigma(f)\sigma(g) \).

It is also very easy to check \( \sigma \) is a \( \mathbb{R} \)-homomorphism, i.e. for \( f, g \in B \) and \( r \in \mathbb{R} \),

\[
\sigma(rf + g) = r\sigma(f) + \sigma(g).
\]

All the above properties will be used frequently in the proof of the new theorem.

Before presenting the new theorem, let study some properties of the ring \( B \) first. These properties will be used in the proof of the new theorem as well. We start with the following definition.

**Definition 4.1.** An element \( (s_f)_{f \in F} \in S(F) \) is homogeneous of degree \( \alpha \), where \( \alpha \in \mathbb{N}^n \), provided that

\[
(s_f)_{f \in F} = (c_f Y^{\alpha_f})_{f \in F},
\]

where \( c_f \in \mathbb{R} \) and \( \alpha_f + \text{deg}(f) = \alpha \) whenever \( c_f \neq 0 \).
The following two lemmas are well-known. For details, please see [Cox et al., 1996].

**Lemma 4.2.** Syz\(_B\)(\(F\)) has a set of homogeneous generators, i.e. there exists a finite set \(C_F \subset S(F)\) such that each element of \(C_F\) is homogeneous and Syz\(_B\)(\(F\)) = \(B\langle C_F \rangle\).

**Lemma 4.3.** Let \(C_F\) be a set of homogeneous generators of Syz\(_B\)(\(F\)). If \((s_f)_{f \in F} \in \text{Syz}_B(F)\) is homogeneous of degree \(\alpha\), then there exists a family \((r_s)_{s \in C_F}\) where \(r_s \in B\), such that

\[
(s_f)_{f \in F} = \sum_{s \in C_F} r_s s
\]

and \(r_s s\) is homogeneous of degree \(\alpha\) for all \(s \in C_F\).

Now, it is time to present the new theorem.

**Theorem 4.4 (Main theorem).** Let \(G\) be a finite subset of \(A \setminus \{0\}\) and \(J\) the ideal in \(A\) generated by \(G\). For each \(g \in G\), assume init\(\{g\} = c_g D^{\alpha_g}\) where \(c_g \in R\) and \(\alpha_g \in N^n\). Let \(C_G\) be a set of homogeneous generators of Syz\(_B\)(\(H_G\)) where \(H_G = \{c_g Y^{\alpha_g} \mid g \in G\}\) ⊂ \(B\) and \(C_G\) is called a set of commutative syzygy generators of init\(\{G\}\) for short. Then the following assertions are equivalent:

(i). \(G\) is a Gröbner basis of \(J\).

(ii). For all \((s_g)_{g \in G} \in C_G\) where \(s_g \in B\) and hence \(\sigma(s_g) \in A\), a remainder of

\[
\text{CSPoly}((s_g)_{g \in G}) := \sum_{g \in G} \sigma(s_g) g
\]

after division by \(G\) is zero.

**Proof:**

\((i) \Rightarrow (ii)\): It follows from Proposition 3.2.

\((ii) \Rightarrow (i)\): Let \(h \in J\). It suffices to show:

\[
lc(h) \in R\langle \text{lc}(g) \mid g \in G, \text{deg}(h) \in \text{deg}(g) + N^n \rangle.
\]

For a family \((f_g)_{g \in G}\) in \(A\), define

\[
\delta((f_g)_{g \in G}) := \max\{\text{deg}(f_g) + \text{deg}(g) \mid g \in G\}.
\]

Since \(h \in J\), there exists a family \((h_g)_{g \in G}\) in \(A\) such that \(h = \sum_{g \in G} h_g g\). Choose \((h_g)_{g \in G}\) such that

\[
\delta := \delta((h_g)_{g \in G}) \text{ is minimal,}
\]

which implies if \((h'_g)_{g \in G}\) is such that \(h = \sum_{g \in G} h'_g g\), then \(\delta \leq \delta((h'_g)_{g \in G})\).

Let \(E := \{g \in G \mid \text{deg}(h_g) + \text{deg}(g) = \delta\} \subset G\).

**Case 1:** deg\(\{h\} = \delta\). Then

\[
\text{init}(h) = \sum_{g \in E} \text{init}(h_g g) \text{ and } \text{lc}(h) = \sum_{g \in E} \text{lc}(h_g) \text{lc}(g) \in R\langle \text{lc}(g) \mid g \in E \rangle.
\]
If \( g \in E \), then \( \deg(h) = \delta = \deg(h_g) + \deg(g) \) and hence \( \deg(h) \in \deg(g) + \mathbb{N}^n \). Therefore, \( \text{lc}(h) \in \mathbb{R} \text{lc}(g) \mid g \in G, \deg(h) \in \deg(g) + \mathbb{N}^n \).

**Case 2:** \( \deg(h) < \delta \). Then

\[
\sum_{g \in E} \text{init}(h_g)g = 0, \text{ which implies } \sum_{g \in E} \text{lc}(h_g)g = 0.
\]

Combined with the fact that \( \deg(h_g) + \deg(g) = \delta \) for \( g \in E \), it follows

\[
0 = \sum_{g \in E} \text{lc}(h_g)gY^\delta = \sum_{g \in E} \text{lc}(h_g)gY^{\deg(h_g)}\text{lc}(g)Y^{\deg(g)} \in B.
\]

Denote

\[
t_g := \begin{cases} \text{lc}(h_g)gY^{\deg(h_g)}, & g \in E, \\ 0, & g \in G \setminus E. \end{cases}
\]

Notice that

\[
\sigma(t_g) := \begin{cases} \text{init}(h_g), & g \in E, \\ 0, & g \in G \setminus E. \end{cases}
\]

Then \( (t_g)_{g \in G} \) is a homogeneous element of \( \text{Syz}_B(H_G) \) with degree \( \delta \). Since \( C_G \) is a set of homogeneous generators of \( \text{Syz}_B(H_G) \), by lemma [13] there exists a family \( (r_s)_{s \in C_G} \) where \( r_s \in B \), such that \( (t_g)_{g \in G} = \sum_{s \in C_G} r_s\sigma(s) \) and \( r_s\sigma(s) \) is homogeneous of degree \( \delta \), i.e. for \( \forall g \in G \),

\[
t_g = \sum_{s \in C_G} r_s\sigma(s), \text{ where } \sigma(s) = (s_g)_{g \in G},
\]

and for \( \forall g \in G, \forall s \in C_G \),

\[
\deg(r_s) + \deg(s_g) + \deg(g) = \delta \text{ whenever } r_s\sigma(s) \neq 0.
\]

**Remark** that all \( t_g, r_s, s_g \in B \).

Now

\[
h = \sum_{g \in G} h_gg = \sum_{g \in E} h_gg + \sum_{g \in G \setminus E} h_gg
\]

\[
= (\sum_{g \in E} h_gg - \sum_{g \in G} \sum_{s \in C_G} \sigma(r_s)\sigma(s_g)g) + \sum_{g \in G} \sum_{s \in C_G} \sigma(r_s)\sigma(s_g)g + \sum_{g \in G \setminus E} h_gg. \tag{1}
\]

For the **FIRST** sum in (1),

\[
\sum_{g \in E} h_gg - \sum_{g \in G} \sum_{s \in C_G} \sigma(r_s)\sigma(s_g)g = \sum_{g \in E} \text{init}(h_g)g - \sum_{g \in G} \sum_{s \in C_G} \sigma(r_s)\sigma(s_g)g + \sum_{g \in E} (h_g - \text{init}(h_g))g
\]

\[
= \sum_{g \in G} \sigma(t_g)g - \sum_{g \in G} \sum_{s \in C_G} \sigma(r_s)\sigma(s_g)g + \sum_{g \in E} (h_g - \text{init}(h_g))g
\]

\[
= \sum_{g \in G} (\sigma(t_g) - \sum_{s \in C_G} \sigma(r_s)\sigma(s_g))g + \sum_{g \in E} (h_g - \text{init}(h_g))g
\]

8
\[
= \sum_{g \in G} \sum_{s \in C_G} (\sigma(r_s g) - \sigma(r_s)\sigma(s_g))g + \sum_{g \in E} (h_g - \text{init}(h_g))g.
\]

Since \(\text{init}(\sigma(r_s g)) = \text{init}(\sigma(r_s)\sigma(s_g))\), then for \(\forall g \in G, \forall s \in C_G,\)

\[
\deg((\sigma(r_s g) - \sigma(r_s)\sigma(s_g))g) < \deg(\sigma(r_s)\sigma(s_g))g = \deg(r_s) + \deg(s_g) + \deg(g) = \delta,
\]

whenever \(r_s g \neq 0\). In case of \(r_s g = 0\) and \(\sigma(r_s)\sigma(s_g) \neq 0\), \(\text{lc}(r_s g) = 0\) implies \(\text{lc}(\sigma(r_s)\sigma(s_g)) = 0\), so the above inequation holds as well. Besides, clearly for \(\forall g \in E,\)

\[
\deg((h_g - \text{init}(h_g))g) < \deg(h_g g) = \delta.
\]

For the \textit{SECOND} sum in \(1\),

\[
\sum_{g \in G} \sum_{s \in C_G} \sigma(r_s)\sigma(s_g)g = \sum_{s \in C_G} \sigma(r_s)\left(\sum_{g \in G} \sigma(s_g)g\right).
\]

For each \(\bar{s} = (s_g)_{g \in G} \in C_G\), assume \(\bar{s}\) is homogeneous of degree \(\beta_{\bar{s}}\), then \(\beta_{\bar{s}} = \deg(\sigma(s_g)) + \deg(g)\) whenever \(\sigma(s_g) \neq 0\), and consider

\[
\sum_{g \in G} \sigma(s_g)g = \sum_{g \in G} \text{init}(\sigma(s_g)g) + \sum_{g \in G} (\sigma(s_g)g - \text{init}(\sigma(s_g)g))
\]

\[= \sum_{g \in G} \text{lc}(\sigma(s_g))\text{lc}(g)D^{\beta_{\bar{s}}} + \sum_{g \in G} (\sigma(s_g)g - \text{init}(\sigma(s_g)g)).\]

By the definition of \(C_G\) and \(\bar{s}\) is a homogeneous element of \(\text{Syz}_G(H_G)\) with degree \(\beta_{\bar{s}}\), then

\[
0 = \sum_{g \in G} s_g c_g Y^{\alpha_{\bar{s}}} = \sum_{g \in G} \text{lc}(s_g)c_g Y^{\beta_{\bar{s}}} \text{ where } \text{init}(g) = c_g D^{\alpha_{\bar{s}}}.
\]

Notice that \(\text{lc}(\sigma(s_g)) = \text{lc}(s_g)\), which implies

\[
\sum_{g \in G} \text{lc}(\sigma(s_g))\text{lc}(g)D^{\beta_{\bar{s}}} = 0.
\]

Combined with the fact \(\deg(\sigma(s_g)g - \text{init}(\sigma(s_g)g)) < \beta_{\bar{s}}\), the following inequation holds:

\[
\deg(\sum_{g \in G} \sigma(s_g)g) < \beta_{\bar{s}}.
\]

By (ii) a remainder of \(\sum_{g \in G} \sigma(s_g)g\) after division by \(G\) is zero, i.e. there exist families \((f_g(\bar{s}))_{g \in G}\) in \(\mathcal{A}\), such that

\[
\sum_{g \in G} \sigma(s_g)g = \sum_{g \in G} f_g(\bar{s})g,
\]

and \(\deg(f_g(\bar{s})g) \leq \deg(\sum_{g \in G} \sigma(s_g)g) < \beta_{\bar{s}}\). So the second sum in \(1\) turns out to be

\[
\sum_{g \in G} \sum_{s \in C_G} \sigma(r_s)\sigma(s_g)g = \sum_{g \in G} \sigma(r_s)(\sum_{g \in G} \sigma(s_g)g) = \sum_{g \in G} \sigma(r_s)(\sum_{s \in C_G} f_g(\bar{s})g).
\]
and for $\forall g \in G$, $\forall s \in C_G$,

$$\deg(\sigma(r_s)f_g(\bar{s})g) < \deg(\sigma(r_s)) + \beta_s = \delta \text{ whenever } r_s \neq 0.$$ 

For the **THIRD** sum in (1), by the definition of $E$, it is obvious that $\deg(h_gg) < \delta$ for $g \in G \setminus E$.

Based on the expressions in (2) and (3), let

$$h'_g := \begin{cases} 
\sum_{s \in C_G}(\sigma(r_s)s_g) - \sigma(r_s)(s_g) + \sigma(r_s)f_g(\bar{s})) + (h_g - \text{init}(h_g)), & g \in E, \\
\sum_{s \in C_G}(\sigma(r_s)s_g) - \sigma(r_s)(s_g) + \sigma(r_s)f_g(\bar{s})) + h_g, & g \in G \setminus E.
\end{cases}$$

Then it is easy to verify that $h = \sum_{g \in G}h'_g g$ and $\delta((h'_g)_{g \in G}) < \delta$, which is a contradiction to the minimality of $\delta$. Hence case 2 never occurs.

To sum up, the theorem is proved. □

The above theorem provides a more fundamental criterion than Insa and Pauer’s original theorem, since it suffices to consider the “s-polynomials” constructed from a set of commutative syzygy generators of $\text{init}(G)$. As we will see in the next section, Insa and Pauer’s original theorem only provides a method for computing the set $C_G$. Thus the new theorem is more essential and the Insa and Pauer’s theorem can be concluded as its natural corollary.

In fact, the main theorem extends much more generally.

**Theorem 4.5.** The main theorem is true for all rings with the quasi-commutative property.

**Proof:** In the proof of the main theorem, only the quasi-commutative property is used. □

Similar to the Insa and Pauer’s approach, one can also develop an algorithm for computing Gröbner basis of $A$ for any given $F \subseteq A$ based on the main theorem. According to theorem 4.4 it suffices to compute one set of commutative syzygy generators of $\text{init}(F)$ in the commutative ring $B$, instead of computing the generators of $\text{Syz}_R(E)$ for all subsets $E \subseteq F$. Clearly, Insa and Pauer’s method leads to more computations than needed. To illustrate this, let see the following example which is from (Zhou and Winkler, 2007).

**Example 4.6.** Let $R = \mathbb{Q}[x_1, \ldots, x_6]$, $A = R[D_1, \ldots, D_6]$ and $J$ the left ideal of $A$ generated by $F = \{f_1, f_2, f_3, f_4\}$, where $f_1 = x_1D_1 + 1$, $f_2 = x_2D_5$, $f_3 = (x_1 + x_2)D_6$, $f_4 = D_5D_6$. Let $\prec$ be the graded lexicographic order with $(1, 0, \ldots, 0) \prec (0, 1, \ldots, 0) \prec (0, \ldots, 0, 1)$.

By Insa and Pauer’s theorem, in order to compute a Gröbner basis for $A(F)$, one needs to consider the following “generalized s-polynomials” (duplicated cases are omitted):

\[
\begin{align*}
\text{SPoly}(\{f_1, f_2\}, (x_2, -x_1)) &= x_2D_5f_1 - x_1D_4f_2, \\
\text{SPoly}(\{f_1, f_3\}, (x_1 + x_2, -x_1)) &= (x_1 + x_2)D_6f_1 - x_1D_4f_3, \\
\text{SPoly}(\{f_1, f_4\}, (1, -x_1)) &= D_5D_6f_1 - x_1D_4f_4, \\
\text{SPoly}(\{f_2, f_3\}, (x_1 + x_2, -x_2)) &= (x_1 + x_2)D_6f_2 - x_2D_5f_3,
\end{align*}
\]
\[
\text{SPoly}\{(f_2, f_4), (1, -x_2)\} = D_6 f_2 - x_2 f_4.
\]
\[
\text{SPoly}\{(f_3, f_4), (1, -(x_1 + x_2))\} = D_5 f_3 - (x_1 + x_2) f_4.
\]
\[
\text{SPoly}\{(f_1, f_2, f_3), (x_2, -x_1, 0)\} = x_2 D_5 D_6 f_1 - x_1 D_4 D_6 f_2.
\]
\[
\text{SPoly}\{(f_1, f_2, f_3), (1, 1, -1)\} = D_5 D_6 f_1 + D_4 D_6 f_2 - D_4 D_5 f_3.
\]
\[
\text{SPoly}\{(f_1, f_2, f_3), (0, 1, -x_2)\} = D_4 D_6 f_2 - x_2 D_4 f_4.
\]
\[
\text{SPoly}\{(f_1, f_3, f_4), (x_1 + x_2, -x_1, 0)\} = (x_1 + x_2) D_5 D_6 f_1 - x_1 D_4 D_5 f_4.
\]
\[
\text{SPoly}\{(f_1, f_3, f_4), (1, -1, x_2)\} = D_5 D_6 f_1 - D_4 D_5 f_3 + x_2 D_4 f_4.
\]
\[
\text{SPoly}\{(f_2, f_3, f_4), (1, -1, x_1)\} = D_6 f_2 - D_5 f_3 + x_1 f_4.
\]

By Zhou and Winkler’s trick, \text{SPoly}\{(f_1, f_2, f_4), (0, 1, -x_2)\}, \text{SPoly}\{(f_1, f_3, f_4), (x_1 + x_2, -x_1, 0)\}, \text{SPoly}\{(f_1, f_3, f_4), (1, -1, x_2)\} and \text{SPoly}\{(f_2, f_3, f_4), (1, -1, x_1)\} can be removed. However, according to the new theorem, \(B = R[y_1, \ldots, y_6]\) and \(H_F = \{x_1 y_4, x_2 y_5, (x_1 + x_2)y_6, y_5 y_6\}\). Then

\[
C_F = \{\bar{s}_1, \bar{s}_2, \bar{s}_3, \bar{s}_4, \bar{s}_5\} = \{(x_2 y_5, -x_1 y_4, 0, 0), ((x_1 + x_2)y_6, 0, -x_1 y_4, 0), (y_5 y_6, 0, 0, -x_1 y_4), (0, y_6, 0, -x_2), (0, 0, y_5, -(x_1 + x_2))\},
\]
is a set of commutative syzygy generators of \(\text{init}(F)\). Therefore, in the new method, it suffices to consider:

\[
\text{CSPoly}(\bar{s}_1) = x_2 D_5 f_1 - x_1 D_4 f_2,
\]
\[
\text{CSPoly}(\bar{s}_2) = (x_1 + x_2) D_5 f_1 - x_1 D_4 f_3,
\]
\[
\text{CSPoly}(\bar{s}_3) = D_5 D_6 f_1 - x_1 D_4 f_4,
\]
\[
\text{CSPoly}(\bar{s}_4) = D_6 f_2 - x_2 f_4,
\]
\[
\text{CSPoly}(\bar{s}_5) = D_5 f_3 - (x_1 + x_2) f_4.
\]

No matter in either Insa and Pauer’s method or Zhou and Winkler’s improved version, one has to compute the remainders of \text{SPoly}\{(f_2, f_3), (x_1 + x_2, -x_2)\} and \text{SPoly}\{(f_1, f_2, f_3), (1, 1, -1)\} all the time, which are not needed any more in the new method. Therefore, the new method avoids all these unnecessary computations and hence has better efficiency.

To finish this example, it is easy to check that all the remainders of \text{CSPoly}(\bar{s}_i) after division by \(F\) are zero. So \(F\) itself is a Gröbner basis for \(\mathcal{A}(F)\).
5. On Computing $C_G$ over $\mathcal{R}[Y]$

So far, as shown by the main theorem 4.4, in order to check if a set of differential operators $G$ is a Gröbner basis for $\mathcal{A}(G)$, it only needs to consider the “$s$-polynomials” deduced by $C_G$, which is a set of commutative syzygy generators of init($G$). Now the last question is how to compute the set $C_G$ over $\mathcal{R}[Y]$?

By the definition of $C_G$, it is a set of homogeneous generators of Syz$_{\mathcal{B}}(H_G)$ which is a syzygy module of monomials in $\mathcal{B} = \mathcal{R}[Y]$. In fact, Insa and Pauer’s theorem implies a natural method to compute it. That is, the set

$$\{(s_e Y^{m(E) - \deg(e)})_{e \in E} \mid (s_e)_{e \in E} \in S_E, E \subset G\},$$

where $S_E$ is a set of generators of Syz$_{\mathcal{R}}(E) = \{(s_e)_{e \in E} \mid \sum_{e \in E} s_e \text{lcm}(e) = 0, s_e \in \mathcal{R}\}$ and $m(E) = (\max_{e \in E} \deg(e)_1, \ldots, \max_{e \in E} \deg(e)_n) \in \mathbb{N}^n$, extends to a set of generators of Syz$_{\mathcal{B}}(H_G)$ naturally. But example 4.6 shows this set is not minimal in general.

Since $\mathcal{B} = \mathcal{R}[Y]$ is a commutative ring, there are many sophisticated results on computing the syzygy of monomials in $\mathcal{B}$, such as the techniques in [Adams and Loustaunau, 1994]. Also Zhou and Winkler’s trick can be exploited for this purpose. Here we only mention two special cases.

(i). $\mathcal{R}$ is a field:
When $\mathcal{R}$ is a field, the following set

$$\{(\text{lcm}(g)^{Y^{m(f,g) - \deg(f)}}, -\text{lcm}(f)^{Y^{m(f,g) - \deg(g)}}) \mid f, g \in G\}$$

extends to a set of generators of Syz$_{\mathcal{B}}(H_G)$.

(ii). $\mathcal{R}$ is the polynomial ring $K[X]$:
Since the variables $X$ commute with $Y$, $C_G$ can be obtained by computing the generators of Syz$_{\mathcal{B}}(H_G)$ in the polynomial ring $K[X,Y]$. Notice that $H_G = \{c_g Y^{\alpha_g} \mid g \in G\} \subset K[X,Y]$. We can obtain a finite set of generators for $\{(s_g)_{g \in G} \mid \sum_{g \in G} s_g c_g Y^{\alpha_g} = 0, s_g \in K[X,Y]\}$ in the polynomial ring $K[X,Y]$ and denote it by $S$. It is straightforward to check that $S$ is also a set of generators for Syz$_{\mathcal{B}}(H_G)$ when considered in $K[X][Y]$. Then the collection of all homogeneous parts of $S$ is a set of homogeneous generators for Syz$_{\mathcal{B}}(H_G)$, since Syz$_{\mathcal{B}}(H_G)$ itself is a graded syzygy module in $(K[X][Y])^{\mathcal{H}_G}$.

6. Conclusion

In this paper, a new theorem which determines if a set of differential operators is a Gröbner basis in the ring of differential operators is proposed. This new theorem is so essential that the original Insa and Pauer’s theorem can be concluded as its natural corollary. Furthermore, based on the new theorem, a new method for computing Gröbner basis in rings of differential operators is deduced. The new method avoids many unnecessary computations naturally and hence has better efficiency than other well-known methods.
