Abstract

The exotic baryon $\Theta^+(uudds)$ is studied with microscopic calculations in a quark model by using a method of antisymmetrized molecular dynamics (AMD). We predict narrow states, $J^\pi = 1/2^+(I = 0)$, $J^\pi = 3/2^+(I = 0)$, and $J^\pi = 3/2^-(I = 1)$, which nearly degenerate in a low-energy region of the $uudds$ system. We discuss $NK$ decay widths and estimate them to be $\Gamma < 7$ for the $J^\pi = \{1/2^+, 3/2^+\}$, and $\Gamma < 1$ MeV for the $J^\pi = 3/2^-$ state.

The evidence of an exotic baryon $\Theta^+$ has recently been reported by several experimental groups. This discovery proved the existence of the multiquark hadron, whose minimal quark content is $uudds$ as given by the decay modes. The study of pentaquarks has become a hot subject in hadron physics. A chiral soliton model [1] predicted a narrow $\Theta^+(J^\pi = 1/2^+)$ state whose parity contradicts the naive quark model expectation. Theoretical studies were done to describe $\Theta^+$ by many groups [2,3]. The spin parity of $\Theta^+$ is not only a open problem but also a key property to understand the dynamics of pentaquark systems.

In this paper we would like to clarify the mechanism of the existence of narrow pentaquark states. We try to extract a simple picture for the pentaquark baryon with levels, width, spin-parity and structure from explicit calculation. In order to achieve this goal, we study the pentaquark with a flux-tube model [6,7] based on strong coupling QCD, by using a AMD method [4,5].
In the flux-tube model, the interaction energy of quarks and anti-quarks is given by the energy of the string-like color-electric flux, which is proportional to the minimal length of the flux-tube connecting quarks and anti-quarks at long distances supplemented by perturbative one-gluon-exchange (OGE) interaction at short distances. For the $q^4\bar{q}$ system the flux-tube configuration has an exotic topology, Fig.1(c), in addition to an ordinary meson-baryon topology, Fig. 1(d). An important point is that the transition between the different flux-tube topologies (c) and (d) is strongly suppressed because it takes place only in higher order. (In 1991, Carlson and Pandharipande studied exotic hadrons in the flux-tube model [8] and calculated a few $q^4\bar{q}$ states with very limited quantum numbers.)

We apply the AMD method to the flux-tube model and calculate the $uudd\bar{s}$ system. The AMD is a variational method to solve a finite many-fermion system. One of the advantages of this method is that the spatial and spin degrees of freedom for all particles are independently treated. This method can successfully describe various types of structure such as shell-model-like structure and clustering (correlated nucleons) in nuclear physics [4,5]. With the AMD method we calculate all the possible spin parity states of $uudd\bar{s}$ system, and analyze the wave function to estimate the decay widths of the obtained states with a method of reduced width amplitudes.

In the present calculation, the quarks are treated as non-relativistic spin-$\frac{1}{2}$ Fermions. We use a Hamiltonian as $H = H_0 + H_I + H_f$, where $H_0$ is the kinetic energy of the quarks, $H_I$ represents the short-range OGE interaction between the quarks and $H_f$ is the energy of the flux tubes. $H_0$ and $H_I$ are represented as follows:

$$H_0 = \sum_i m_i + \sum_i \frac{p_i^2}{2m_i} - T_0, \quad (1)$$

$$H_I = \alpha_c \sum_{i<j} F_i^\alpha F_j^\alpha \left[ \frac{1}{r_{ij}} - \frac{2\pi}{3m_i m_j} s(r_{ij}) \sigma_i \cdot \sigma_j \right], \quad (2)$$

where $m_i$ (the $i$-th quark mass) is $m_q$ for a $u$ or $d$ quark and $m_s$ for a $\bar{s}$ quark, and $T_0$ denotes the kinetic energy of the center-of-mass motion. Here, we do not take into account the mass difference between $ud$ and $s$ in the second term of $H_0$, for simplicity. $\alpha_c$ is the quark-gluon coupling constant, and $F_i^\alpha$ is the generator of color $SU(3)$. In $H_I$, we take only the dominant
terms, Coulomb and color-magnetic terms, and omit other terms.

\[ H_f = \sigma L_f - M^0 \]

where \( \sigma \) is the string tension, \( L_f \) is the minimum length of the flux tubes, and \( M^0 \) is the zero-point energy. \( M^0 \) depends on the topology of the flux tubes and is necessary to fit the \( q\bar{q} \), \( q^3 \) and \( q^4\bar{q} \) potential. In the present calculation, we adjust the \( M^0 \) to fit the absolute masses for each of 3q-baryon and pentaquark. For the meson and 3q-baryon systems, the flux tube configurations are given as Fig. 1(a) and (b). For the pentaquark system, the different types of flux-tube configurations appear as shown in Fig. 1(e), (f), and (d), which correspond to the states, \(|\Phi_{(e)}\rangle = |[ud][ud]\bar{s}\rangle\), \(|\Phi_{(f)}\rangle = |[uu][dd]\bar{s}\rangle\), and \(|\Phi_{(d)}\rangle = |(qqq)_{1}(qqq)_{1}\rangle\), respectively (\( [qq] \) is defined by color anti-triplet of \( qq \)). In the present calculation of energy variation, we neglect the transitions among \(|\Phi_{(e)}\rangle\), \(|\Phi_{(f)}\rangle\) and \(|\Phi_{(d)}\rangle\) and solve 5q wave functions within the model space (e) or (f), which corresponds to the confined states. It is reasonable because the transitions are suppressed as mentioned before. In the practical calculations of the string potential \( \langle \Phi | H_f | \Phi \rangle \), the minimum length of the flux tubes \( L_f \) is approximated by a linear combination of two-body distances as \( L_f \approx \frac{1}{2}(r_{12} + r_{23} + r_{31}) \) for a 3q-baryon, and \( L_f \approx \frac{1}{2}(r_{12} + r_{34}) + \frac{1}{3}(r_{13} + r_{14} + r_{23} + r_{24}) + \frac{1}{3}(r_{11} + r_{12} + r_{13} + r_{14}) \) for \( \Phi_{(e)} \) or \( \Phi_{(f)} \) of the pentaquark systems. We note that the confinement is reasonably realized by the approximation for \( \Phi_{(e,f)} \) as follows. The flux-tube configuration (e)(or f) consists of seven bonds and three junctions. In the limit that the length(\( R \)) of any one bond becomes much larger than other bonds, the approximated \( \langle H_f \rangle \) behaves as a linear potential \( \sigma R \). It means that all the
quarks and anti-quarks are bounded by the linear potential with the tension $\sigma$. Therefore, the approximation for $\Phi_{(e)}$ or $\Phi_{(f)}$ is a natural extension of the usual approximation for $3q$-baryons. It is easily proved that the approximations are equivalent to $\langle \Phi | H_f | \Phi \rangle \approx \langle \Phi | \hat{O} | \Phi \rangle$, where $\hat{O} \equiv -\frac{3}{4}\sigma \sum_{i<j} F_{ij} F_{ij} - M^0$, within each of the flux-tube configurations.

We solve the eigenstates of the Hamiltonian with a variational method in the AMD model space [4,5]. We take a base AMD wave function in a quark model as follows.

$$\Phi(Z) = (1 \pm P)A \left[ \phi_{Z1} \phi_{Z2} \cdots \phi_{ZN_q} X \right], \quad \phi_{Zi} \propto e^{-\frac{1}{2\sigma^2}(r - \sqrt{2}bZ_i)^2}, \quad (3)$$

where $1 \pm P$ is the parity projection operator, $A$ is the anti-symmetrization operator, and the spatial part $\phi_{Zi}$ of the $i$-th single-particle wave function is written by a Gaussian with the center $Z_i$ ($Z_i$ is a complex parameter). $X$ is the spin-isospin-color function. For the pentaquark($uudd\bar{s}$) system, $X$ is expressed as

$$X = \sum_{m_1, m_2, m_3, m_4, m_5} c_{m_1 m_2 m_3 m_4 m_5} \langle m_1 m_2 m_3 m_4 m_5 | s \rangle \otimes \{ | udud\bar{s} \rangle \text{ or } | uudd\bar{s} \rangle \} \otimes \epsilon_{abc}\epsilon_{def} \langle abce | c \rangle, \quad (4)$$

where $| udud\bar{s} \rangle$ and $| uudd\bar{s} \rangle$ correspond to the configurations $[ud][ud]\bar{s}$ and $[uu][dd]\bar{s}$ in Fig.1, respectively. Here, $| a \rangle_C (a = 1, 2, 3)$ denotes the color function, and $| m \rangle_S (m = \uparrow, \downarrow)$ is the intrinsic-spin function. Since we are interested in the confined states, we adopt those model space for the color configurations $(qq)_{3}(qq)_{3}\bar{q}$, but do not use the meson-baryon configurations $(qqq)_{1}(q\bar{q})_{1}$. The variational parameters are $Z = \{Z_1, Z_2, \cdots, Z_5\}$ and $c_{m_1 m_2 m_3 m_4 m_5}$ which specify the spatial and spin configurations. The energy variation for $Z$ is performed by a frictional cooling method, and the coefficients $c_{m_1 m_2 m_3 m_4 m_5}$ are determined by diagonalization of Hamiltonian and norm matrices. After the energy variation, the intrinsic-spin and parity $S^\pi$ eigen wave function $\Phi(Z)$ for the lowest state is obtained for each $S^\pi$.

In the numerical calculation, the linear and Coulomb potentials are approximated by seven-range Gaussians. We use the parameters, $\alpha_c = 1.05$, $\Lambda = 0.13$ fm, $m_q = 0.313$ GeV, $\sigma = 0.853$ GeV/fm, and $\Delta m_s = m_s - m_q = 0.2$ GeV. The quark-gluon coupling constant $\alpha_c$ is chosen so as to fit the $N$ and $\Delta$ mass difference. The string tension $\sigma$ is adopted to
adjust the excitation energy of \( N^*(1520) \). The width parameter \( b \) is chosen to be 0.5 fm. By choosing \( M_0 \) as \( M_0^0 = 972 \) MeV, the masses of \( N, N^*(1520) \) and \( \Delta \) are fitted \([10]\), and the masses of \( \Lambda, \Sigma \) and \( \Sigma^*1385 \) are well reproduced with these parameters.

Now, we apply the AMD method to the \( uudd\bar{s} \) system. For each spin parity, we calculate energies of the \([ud][ud]\bar{s}\) and \([uu][dd]\bar{s}\) states and adopt the lower one. In table.I, the calculated results are shown. We adjust the zero-point energy of the string potential \( M_0 \) as \( M_0^4 = 2385 \) MeV to fit the absolute mass of the recently observed \( \Theta^+ \). This \( M_0^4 \) for pentaquark system is chosen independently of \( M_0^3 \) for 3q-baryon. If \( M_0^4 = \frac{5}{3} M_0^3 \) is assumed as Ref.\([8]\), the calculated mass of the pentaquark is around 2.2 GeV, which is consistent with the result of Ref.\([8]\).

The most striking point in the results is that the \( S^\pi = 3/2^- \) and \( S^\pi = 1/2^+ \) states nearly degenerate with the \( S^\pi = 1/2^- \) states. The \( S^\pi = 1/2^+ \) correspond to \( J^\pi = 1/2^+ \) and \( 3/2^+ \) with \( S = 1/2, L = 1 \), and the \( S^\pi = 3/2^- \) is \( J^\pi = 3/2^- (S = 3/2, L = 0) \). The lowest state \( J^\pi = 1/2^- (S^\pi = 1/2^-, L = 0) \) exists just below the \( J^\pi = 3/2^- \) state, however, this state, as we discuss later, is expected to be much broader than other states. Other spin-parity states are much higher than these low-lying states.

The \( LS \)-partners, \( J^\pi = 1/2^+ \) and \( 3/2^+ \) exactly degenerate in the present Hamiltonian where the spin-orbit and tensor terms are omitted. If we introduce the spin-orbit force into the Hamiltonian the \( LS \)-splitting is small in the diquark structure because the effect of the spin-orbit force from the spin-zero diquarks is very weak as discussed in Ref.\([12]\). As shown later, since the present results show that the diquark structure is realized in the \( J^\pi = 1/2^+ \) and \( 3/2^+ \) states, the \( LS \)-splitting should not be large in the \( uudd\bar{s} \) system.

Next, we analyze the spin structure of these states, and found that the \( J^\pi = \{1/2^+, 3/2^+\} (S = 1/2, L = 1) \) states consist of two spin-zero \( ud \)-diquarks, while the \( J^\pi = 3/2^- \) consists of a spin-zero \( ud \)-diquark and a spin-one \( ud \)-diquark. Since the spin-zero \( ud \)-diquark has the isospin \( I = 0 \) and the spin-one \( ud \)-diquark has \( I = 1 \) because of the color asymmetry, the isospin of the \( J^\pi = 3/2^- \) state is \( I = 1 \), while the even-parity states \( J^\pi = 1/2^+, 3/2^+ \) are \( I = 0 \). We consider that the \( J^\pi = 1/2^+ \) state corresponds to
TABLE I. Calculated masses(GeV) of the $uudd\bar{s}$ system. The expectation values of the kinetic, string, Coulomb, color-magnetic terms, and that of the color-magnetic term in $q\bar{q}$ pairs are listed. The $S^\pi = 3/2^+$ and $S^\pi = 5/2^+$ states are higher than the $S^\pi = 5/2^-$ state.

The $\Theta^+(1530)$ in the flavor $\overline{10}$-plet predicted by Diakonov et al. [1]. The odd-parity state, $J^\pi = 3/2^-$ has $I = 1$, which means that this state is a member of the flavor 27-plet. We denote the $J^\pi = 1/2^+, 3/2^+(I = 0)$ by $\Theta_0^+$, and the $J^\pi = 3/2^-(I = 1)$ by $\Theta_1^+$.

Although it is naively expected that unnatural spin parity states are much higher than the natural spin-parity $1/2^-$ state, the results show the abnormal level structure of the $(uddsd)$ system, where the high spin state, $J^\pi = 3/2^-$, and the unnatural parity states, $J^\pi = \{1/2^+, 3/2^+\}$, nearly degenerate just above the $J^\pi = 1/2^-$ state. By analysing the details of these states, the abnormal level structure can be easily understood with a simple picture as follows. As shown in table I, the $J^\pi = \{1/2^+, 3/2^+\}(S = 1/2, L = 1)$ states have larger kinetic and string energies than the $J^\pi = 3/2^-(S = 3/2, L = 0)$ and $J^\pi = 1/2^-(S = 1/2, L = 0)$ states, while the former states gain the color-magnetic interaction. It indicates that the degeneracy of the even-parity states with the odd-parity states is realized by the balance of the loss of kinetic and string energies and the gain of the color-magnetic interaction. In the $J^\pi = \{1/2^+, 3/2^+\}$ and the $3/2^-$ states, the competition of the energy loss and gain can be simply understood from the point of view of the diquark structure as follows. As already mentioned by Jaffe and Wilczek [2], the relative motion between two
FIG. 2. $q$ and $\bar{q}$ density distribution in the $J^\pi = 1/2^+, 3/2^+ (S = 1/2, L = 1)$ states of $\Theta^+$. The $u$-quark density (a), $s$ density (b), and total quark-antiquark density (c) of the intrinsic state before parity projection are shown. The $d$-quark density is same as the $u$-quark density. The root-mean-square radius of $q$ and $\bar{q}$ is 0.63 fm (the nucleon size is 0.5 fm).

Spin-zero diquarks must have the odd parity ($L = 1$) because of Pauli blocking between the two identical diquarks. In the $J^\pi = 3/2^-$ state, one of the spin-zero $ud$-diquarks is broken to be a spin-one $ud$-diquark to avoid the Pauli blocking, then, the $L = 0$ is allowed because diquarks are not identical. The $L = 0$ is energetically favored in the kinetic and string terms, and the energy gain cancels the color-magnetic energy loss of a spin-one $ud$-diquark. Although we can not describe the $J^\pi = 1/2^-$ state by such a simple diquark picture, the competition of energy loss and gain in this state is similar to the $J^\pi = 3/2^-$. We remark that the existence of two spin-zero $ud$-diquarks in the $J^\pi = \{1/2^+, 3/2^+\}$ states predicted by Jaffe and Wilczek [2] is actually confirmed in our ab initio calculations. We found that the component with two spin-zero $ud$-diquarks is 97% in the present $J^\pi = \{1/2^+, 3/2^+\}$ state. In Fig.2, we show the quark and anti-quark density distributions in the $J^\pi = \{1/2^+, 3/2^+\}$ states. In the intrinsic state before parity projection, we found the spatial development of $ud-uds$ clustering, which causes a parity-asymmetric shape (Fig.2 (c)).

We estimate the $KN$-decay widths of these states by using a method of reduced width amplitudes [11]. The decay width $\Gamma$ is estimated by the product $\Gamma^0_L \times S_{fac}$, where $\Gamma^0_L(a, E_{th})$ is given by the penetrability of the barrier [10], and $S_{fac}(a)$ is the probability of the decaying particle at the channel radius $a$. In the following discussion, we use the channel radius $a = 1$ fm and the threshold energy $E_{th} = 100$ MeV. We here estimate the maximum values of the
widths, by taking into account only quark degrees of freedom. We omit the suppression of the transition between the confined state and the meson-baryon state due to the rearrangement of flux-tubes, which makes $S_{fac}$ small in general.

In case of even parity $J^\pi = 1/2^+, 3/2^+$ states, the $KN$ decay modes are the $P$-wave, which gives $\Gamma_{L=1}^0 \approx 100$ MeV fm$^{-1}$. We calculate the overlap between the obtained pentaquark wave function and the $K^+n$ state, and evaluate the probability as $S_{fac} = 0.034$ fm$^{-1}$. Roughly speaking, the main factors in this meson-baryon probability are the factor $1/3$ from the color configuration, the factor $1/4$ from the intrinsic spin part, and the other factor which arises from the spatial overlap. By using this value, the total width for $K^+n$ and $K^0p$ decays of the $J^\pi = 1/2^+, 3/2^+$ states is estimated to be $\Gamma < 7$ MeV. For more quantitative discussions, it is important to treat the coupling with the $KN$ continuum states, where one must take into account the suppression due to the rearrangement of flux-tube topologies.

It is interesting that the $KN$ decay width of the $J^\pi = 3/2^-$ state is extremely small due to the $D$-wave centrifugal barrier. In fact, $\Gamma_{L=2}^0 \approx 30$ MeV fm$^{-1}$ is much smaller than the $P$-wave case. Moreover, the $J^\pi = 3/2^- (S^\pi = 3/2^- L = 0)$ has no $D$-wave component, therefore, no overlap with the $KN (L = 2)$ states in the present calculation. Even if we introduce the spin-orbit or tensor forces, the $KN$ probability($S_{fac}$) in the $J^\pi = 3/2^-$ pentaquark state is expected to be minor. Consequently, the $J^\pi = 3/2^-$ state should be extremely narrow. If we assume the $S_{fac}$ in the $J^\pi = 3/2^-$ to be half of that in the $J^\pi = 1/2^+, 3/2^+$ states, the $KN$ decay width is estimated to be $\Gamma < 1$ MeV. Contrary to the narrow features of the $J^\pi = 3/2^-$ state, in case of $J^\pi = 1/2^-$, $S$-wave($L = 0$) decay is allowed and this state should be much broader.

In conclusion, we proposed a quark model in the framework of the AMD method, and applied it to the $uudd\bar{s}$ system. The level structure of the the $uudd\bar{s}$ system and the properties of the low-lying states were studied. We predicted that the narrow $J^\pi = \{1/2^+, 3/2^+\} (\Theta_{I=0})$ and $J^\pi = 3/2^- (\Theta_{I=1})$ states nearly degenerate. The widths of $\Theta_0^+$ and $\Theta_1^+$ are estimated to be $\Gamma < 7$ MeV and $\Gamma < 1$ MeV, respectively. Two spin-zero diquarks are found in the $\Theta_0^+$, which confirms Jaffe-Wilczek picture. The origin of the novel level structure is the $5q$
dynamics of the confined system bounded by the connected flux-tubes. We consider that the present results for the $J^\pi = \{1/2^+, 3/2^+\}(\Theta^+_I=0)$ states correspond to the experimental observation of $\Theta^+$, while the $\Theta^+_{I=1}$ is not observed yet. The existence of many narrow states, $J^\pi = 1/2^+, 3/2^+$, and $3/2^-$, may give an light to further experimental observations.

Concerning other pentaquarks, we give a comment on $\Xi(\bar{d}d\bar{s}s\bar{u})$. The AMD calculations indicate that the diquark structure disappears in the $\bar{d}d\bar{s}s(1/2^+)$ due to the $SU(3)$-symmetry breaking in the color-magnetic interaction. As a result, the estimated width of the $\bar{d}d\bar{s}s(1/2^+)$ state is $\Gamma \approx 100$ MeV, which is much broader than $\Theta^+(1/2^+)$. Also the $3/2^-$ state is not so narrow because a $S$-wave decay channel $\Xi^*(1530)\pi$ is open.

Finally, we would like to remind the readers that the absolute masses of the pentaquark in the present work are not predictions. We have an ambiguity of the zero-point energy of the string potential, which depends on the flux-tube topology in each of meson, $3q$-baryon, pentaquark systems. We adjust that for the pentaquarks to reproduce the observed $\Theta^+$ mass. To confirm the zero-point energy, experimental information for other pentaquark states are desired.

The authors would like to thank to T. Kunihiro, Y. Akaishi and H. En’yo for valuable discussions. This work was supported by Japan Society for the Promotion of Science and Grants-in-Aid for Scientific Research of the Japan Ministry of Education, Science Sports, Culture, and Technology.
