ABSTRACT

Gluten-rich foods are staple foods in many countries because they are nutritious, tasty and cosmopolitan, but lately, concerns are rife about the safety of gluten, necessitating an in-depth investigation. This study, therefore, evaluated the toxicity of two gluten-rich foods, namely wheat (Triticum aestivum) and barley (Hordeum vulgare). Eighteen (18) mixed-sex experimental rats (Rattus norvegicus) were divided into 3 groups of 6 rats each. Group 1 was made the control, while groups 2 and 3 were fed ad libitum barley and wheat diets, respectively. The rats were monitored daily for 60 days, after which blood samples were taken for hematological and liver function tests. The livers, hearts, kidneys, and ovaries of the rats were also collected for histopathological examination. The hematological parameters of the test rats, including the packed cell volume (PCV), hemoglobin (Hb), white blood cells (WBC), red blood cells (RBC), and lymphocytes (LYM) had no statistical significance (p>0.05), while the liver enzymes, including the alkaline phosphatase (ALP), alanine aminotransferase (ALT), total protein (TP), and albumin (ALB) were significantly elevated. There were no histopathological changes in the livers, kidneys, hearts, and ovaries of the test rats compared with the control. The rats in the wheat group completed 2 reproductive cycles, while the barley and control rats made 1 cycle each. On average, the number of offspring per birth of the control was 8, while the barley and wheat groups had 9 and 12, respectively. The offspring survival rate of the control was 90%, whereas the barley and wheat rats had 89.91 and 90.20%, respectively. The results obtained showed that the gluten diets did not induce any serious side effect in the treated rats and even enhanced the health of the rats, particularly the reproductive performance. Gluten-rich foods are therefore considered safe and healthy for gluten-tolerant individuals.

Keywords: ALP, Gluten, Histopathology, PCV, Wheat.

Introduction

Gluten is a compound name given to several distinct but related proteins, grouped into a fraction formed by alcohol-soluble prolamins and another fraction formed by alcohol-insoluble glutelins (Wieser et al., 1998). Gluten can also be classified into sulfur-rich (S-rich), sulfur-poor (S-poor) and high-molecular-weight proteins (Balakireva and Zamyatnin, 2016). Gluten is the main storage protein of cereals such as wheat (Triticum aestivum), barley (Hordeum vulgare), rye (Secale cereal), and oats (Avena sativa) (Biesiekierski, 2017). Gluten cannot be denatured
by heat and so it is used as a food additive to improve texture, flavor, and moisture retention (Kucek et al., 2015). Because of these properties, gluten is present in products such as processed meat, reconstituted seafood, candies, ice cream, butter, seasonings, stuffings, marinades, and confectionery, among others (Kucek et al., 2015).

Gluten-rich diets form an important part of human daily energy intake and nutritional requirements. For example, wheat is the major cereal in some countries and is particularly increasingly popular in developing nations (Balk et al., 2019). According to FAO (2019), world cereal production may reach a record of 2722 million tons in 2019, of which wheat, maize, and barley would account for most of the rise. The acceptability of wheat is owing to its adaptability, high yield potential, and gluten content responsible for the viscoelasticity of dough processed into bread, pasta, noodles, etc. (Shewry, 2009). Wheat is also rich in amino acids, minerals, vitamins, beneficial phytochemicals, and fibre (Shewry, 2009). Barley is another highly adaptable gluten food, which ranked 4th in the term of production behind wheat, maize, and rice (Zhou, 2010). Barley is widely consumed as food and drink because of its high nutritional content, particularly, it is a rich source of carbohydrates and beta-glucan compared to other cereals (Noaman, 2017).

However, there is an ongoing debate on the health safety of gluten-rich diets. Some studies, including Lerner et al. (2017) and Schalk et al. (2017) implicated gluten diets in hypersensitivity reactions such as celiac disease, non-celiac gluten sensitivity, and cytotoxic and inflammatory effects. On the other hand, several studies such as Neyrinck et al. (2012) and Shewry and Hey (2015) linked gluten-rich diets with some health benefits such as reduced heart disease and stroke, development of type 2 diabetes, and increased probiotic activities. This controversy has led to a significant increase in the adoption of gluten-free diets in the last few decades (Niland and Cash, 2018). Thus, an in-depth study becomes imperative to provide information towards the evaluation of health risks of gluten consumption and formulate palliative strategies if found toxic. This will go a long way to restore the confidence of consumers. This study, therefore, evaluated the toxicity of gluten-rich wheat and barley in experimental rats (Rattus norvegicus).

Materials and Methods

Description of the Study Site

This study was carried out in Birnin Kebbi, Kebbi State, northwestern Nigeria (Figure 1). Birnin Kebbi is the capital of Kebbi State and the headquarters of Gwandu emirate on longitude 12º21’N and longitude 4º36’E (Ajala et al., 2019). The state is bordered by Katsina and Zamfara State in the west, Sokoto State up north, Niger State in the south as well as Niger and Benin Republic in the east. The people of the state are predominantly farmers and cattle breeders and are famous in the country for cereal production.

The natural vegetation of the state is an intermix of Sudan and Guinea Savannah. However, long-term anthropogenic activities have changed the natural vegetation of the area. On average, Birnin Kebbi has a monthly and an annual rainfall of 112.21 mm and 787.53 mm, respectively, with a rainy season spanning through April and October, and reaching the peak periods in June, July, August, and September (Ismail and Oke, 2012). The average temperature is 26 ºC but could rise above 40 ºC in the peak of the hot season (March-July) and fall as low as 21 ºC during the harmattan, between December and February (Gulma, 2013).

Source of Animal Material

Guide of care and use of animals in research and teaching of the Animal Ethics Committee of Federal University Birnin Kebbi, Nigeria, were
followed in this study. Eighteen (18) mixed-sex rats, aged 50 days and weight 200 ± 10 g were sourced from the Department of Biology, Federal University Birnin Kebbi, Nigeria in December 2018. The rats were maintained in metal cages and allowed to acclimatize to the ambient conditions for 14 days before the study began. The rats had free access to water and corn feeds.

**Collection and Preparation of Wheat and Barley Diets**

Some quantities of wheat and barley grains were purchased from Jos and Birnin Kebbi, both in Nigeria in February 2019. The grains were identified by a curator in the Department of Botany’s Herbarium, University of Lagos, Nigeria. Samples of the authenticated materials with voucher numbers LUH 8654 and LUH 8655 for *T. aestivum* and *H. vulgare*, respectively, were kept in the herbarium. The grains were ground into coarse feeds using a mortar and pestle and kept in a desiccator before use.

**Study Design**

The rats were divided into three (3) groups, comprising 6 rats each (3 males and 3 females). Group 1 was made the control and rats in the group were administered corn meals, while groups 2 and 3 were fed barley and wheat *ad libitum*, respectively. The rats were monitored daily for 60 days, after which they were sedated with chloroform in a bell-shaped glass jar and blood samples were taken for hematological and liver function tests. The rats were then sacrificed by cervical dislocation and selected internal organs, including the livers, hearts, kidneys, and ovaries, were collected for histopathological examination. All the reagents used for the experiments were sourced from chemicals of pure analytical grades.

**Evaluation of Reproductive Performance**

The reproductive performance of the rats was evaluated from the numbers of reproductive cycle completed by females in each group and the number of offspring born per birth. The offspring survival rate in each group was also calculated by taking the percentage of offspring that survived from the total offspring born per female.

**Hematological Tests**

**Determination of Packed Cell Volume (PCV)**

The PCV was determined by the micro-hematocrit centrifuge method described by Bull and Hay (2001). Two-third of a capillary tube was filled with each of the blood samples and one end of the tube was sealed using a Bunsen burner flame to prevent leakage, before and during spinning in the hematocrit centrifuge machine. The capillary tubes were labeled, arranged in the micro-hematocrit centrifuge machine, and centrifuged at 12000 rpm for five minutes. The centrifugation separated the blood plasma from the red blood cells in the tubes, which was then measured using a micro-hematocrit reader.

**Determination of Hemoglobin (Hb)**

The Hb content was measured using the cyanmethemoglobin method as described by Hope *et al.* (2019). About 0.02 ml blood was transferred into a test tube containing 5 ml Drabkin’s reagent. The solution was mixed thoroughly and allowed to stand for 10 minutes at 250 °C to allow cyanmethaemoglobin to form. The mixture was then transferred into a cuvette and read on a spectrophotometer at a wavelength of 540nm. The reading recorded was compared with a pre-calibrated chart to obtain the actual Hb values in g/dl.

**Determination of White (WBC) and Red Blood Cells (RBC)**

The WBC and RBC were estimated using the improved Neubauer hemocytometer as described by Cheekurthy (2019). The blood samples were diluted at a ratio 1:200 with ammonium oxalate and Hayem’s solution and added to the hemocytometer chamber. The WBC being bigger
was counted from the four corner squares of the chamber. To estimate the RBC, the small squares in the middle of the chamber were zoomed, and the RBC counted.

**Determination of Lymphocytes**

The lymphocyte cells were estimated as described by Heather and Tim (2016). A drop of each blood sample was smeared on a clean glass slide and stained with a Wright-Giemsa dye, which helped to differentiate the sub-types of the WBC in the sample. The number of lymphocyte cells was then calculated using an automated blood count machine.

**Liver Function Tests**

**Determination of Alanine Amino Transferase (ALT)**

The ALT activity was estimated by colorimetric method described by Mirmiran et al. (2019). The blood samples were centrifuged at 3000 rpm for 5 minutes to separate the blood serum. A reagent, 2, 4 dinitrophenyl hydrazine was added to the blood serum, producing pyruvate hydrazine. The ALT was measured using a Cobas Mira Plus CC Chemistry Analyzer (Switzerland), based on the colorimetric measurement of pyruvate hydrazine formed.

**Determination of Aspartate Aminion Transferase (AST)**

The same colorimetric method used to determine the ALT activity was also used for the AST. However, the reagent, 2, 4 dinitrophenyl hydrazine was replaced with 2, 4 nitrophenyl hydrazine, producing oxaloacetate hydrazine. The colorimetric measurement of the oxaloacetate hydrazine concentration was used to estimate the AST activity.

**Determination of Alkaline Phosphatase (ALP)**

The ALP activity was determined using the spectrophotometric method described by Bergmeyer and Bernt (1974). About 0.02 ml of the blood serum was added to 1.0 ml diethanolamine buffer, pH 9.9, magnesium chloride (MgCl₂), and a substrate, p-nitrophenyl phosphate. The mixture produced was stirred, and the absorbance was taken over 1, 2 and 3 minutes using a timer at 405 nm in a spectrophotometer. Change in absorbance taken after 2 and 3 minutes was used to determine the final absorbance of ALP.

**Determination of Total Protein (TP)**

The Biuret method described by Layne (1957) was used to determine the TP. About 0.02 ml of the blood sample was treated with an equal volume of 1% sodium hydroxide followed by a few drops of aqueous copper (II) sulfate. The mixture was stirred and incubated for 10 minutes at room temperature, after which the absorbance of the colored solution was read at 546 nm.

**Determination of Albumin (ALB)**

The bichromatic digital endpoint method described by Kelly (1979) was used to determine the ALB concentrations. About 1.0 ml of Brom cresol purple (BCP) was added to 0.02 ml of the blood serum, producing BCP–ALB complexes. The change in the absorbance at 600 nm was measured with a spectrophotometer and considered the concentration of ALB in the sample.

**Histopathological Examination**

The tissues were prepared for histological examination based on the method of Geoffrey (2019). About 5 mm sample of each selected organ was fixed in 10% formal saline for 8 hours, after which they were dehydrated with ethanol. A xylene solution was used to absorb the ethanol to enable infiltration by paraffin wax heated at 55° C. Thin sections about 6 μ thick were then cut from the wax-embedded tissues and placed on clean glass slides. The slides were stained with hematoxylin and eosin and viewed with a light microscope.
Data Analysis

The Statistical Package for Social Science (SPSS) version 20 for Windows was used for all the analyses. Comparison of data among the test and control groups was done using the student’s t-test. P<0.05 was considered statistically significant.

Results and Discussion

Effects of Gluten-Rich Diets on Hematological Parameters

Table 1 shows the hematological profile of the rats fed wheat and barley diets. Compared with the control, no significant differences (p>0.05) were observed in the blood counts (PCV, Hb, WBC, RBC, and LYM) of the treated groups. This suggests that gluten had no effect on blood parameters, which are major health indices of animals, including humans. Hansen et al. (2018) reported similar findings between gluten and non-gluten fed individuals regarding leukocytes, lymphocytes, neutrophils, and monocytes counts. Gluten-rich whole grains have antioxidants and blood-forming vitamins and minerals such as the B vitamins, iron, copper, zinc, magnesium (Havard School of Public Health, 2019). But a study by Kooy-Winkelaar et al. (2017) indicated that gluten can interact with immune cells to produce cytokines, which predispose to cancer of the WBC. This condition, however, was observed in gluten-sensitive individuals, indicating that it may not occur in non-sensitive individuals.

Effects of Gluten-Rich Diets on Liver Enzymes

The effects of the gluten-rich diets in the liver enzymes of the treated rats are revealed in Table 2. In comparison with the control, the liver enzymes of the treated rats were altered at the end of the administration. The changes were significant (p<0.05) in the ALP, ALT, TP, and ALB of the rats fed barley as well as ALP, ALT, and TP of the rats administered wheat. However, the levels of the enzymes remained within the normal ranges. This shows that gluten consumption may not cause serious biochemical problems. According to Gasteyger et al. (2008), a low-calorie diet (like the gluten-rich diets) may cause transient increases in...

Figure 1: Maps Showing Locations of Birnin Kebbi, Nigeria
liver enzymes, especially in females. Metwally and Farahat (2015) reported similar observations in the liver enzymes, including the TP, ALB, and globulin of birds fed a rice gluten diet. Hansen et al. (2018) also found no differences in the levels of glucose and lipid metabolism between individuals placed on gluten diets and non-gluten diets.

**Effects of Gluten-Rich Diets on Reproductive Performance**

Table 3 describes the effects of wheat and barley diets on the reproductive activities of the treated rats. During the 60-day feed administration, the rats fed the wheat diet completed two reproductive cycles, while the barley and control rats made one. The wheat-fed rats also had the highest number of offspring per birth (12), followed by barley (9), and control rats (8), respectively. The offspring survival rate of the rats was highest in the wheat group (90.20%), followed by the control rats (90.00%), and barley rats (89.91%), respectively. These results suggest that certain substances in gluten or gluten-containing diets can boost reproductive activities in animals, including humans. According to Neyrinck et al. (2012) and Tojo et al. (2014), gluten may act as a prebiotic, boosting the growth of beneficial gut bacteria such as the bifidobacteria, which modulates important metabolic and physiological functions. Through this mechanism, the gluten diets might boost the rats’ metabolic and physiological activities related to reproductive performances. In addition, whole grains containing gluten, such as the wheat and barley contain selenium, zinc, and magnesium as well as tocols, which stimulate vitamin E activity (Brigid, 2004; Shewry and Hey, 2015). Selenium, zinc, magnesium and vitamin E are very important in reproductive activities. The normal offspring survival rates of the treated rats showed the health-protective role of gluten. In a study that evaluated the effects of gluten, groups with the highest intakes of gluten-containing diets had lower rates of type 2 diabetes and deaths (Mellen et al., 2008).

**Histopathological Effects of the Gluten-Rich Diets**

Plates 1-4 describe the histology of the rats treated with wheat and barley diets. The kidney tissues of the control and rats treated with wheat and barley diets showed normal glomeruli and tubules [Plate 1 (a, b, and c)], while normal cardiac myocytes were found in the heart tissues of the control and rats administered wheat and barley [Plate 2 (a, b, and c)]. The liver tissues of the control rats showed normal hepatocytes, which were also observed in the livers of the rats fed wheat and barley [Plate 3 (a, b, and c)]. Plate 4 (a, b, and c) showed that the ovaries of the control and barley rats had normal ovarian follicles, while normal papillary luminal architecture was observed in the rats fed wheat. These results showed that gluten did not induce any histopathological effects. Lebwohl et al. (2017) reported similar findings in which long-term consumption of gluten did not induce any heart injury. Viljamaa et al. (2005) and Guidetti et al. (2001) also reported no increased risk of autoimmune diseases following gluten diets consumption. In a study that monitored the effects of a low-gluten diet on immune and inflammatory responses, no changes were seen in the concentrations of systemic inflammatory markers in serum (Hansen et al., 2018). According to Kumar (2011) and Rosell (2012), gluten diets contain a considerable amount of carbohydrates, protein, calcium, iron, zinc, magnesium, phosphorus, potassium, phytochemicals, and vitamins B and E, all which protect and repair tissues.
Table 1: Hematological Parameters of Rats Feed with Wheat and Barley

| Parameters | Control | Wheat | Barley |
|------------|---------|-------|--------|
| PCV (L L⁻¹) | 0.28 ± 0.05ᵃ | 0.29 ± 0.06ᵃ | 0.29 ± 0.05ᵃ |
| Hb (g dL⁻¹) | 10.80 ± 1.60ᵃ | 10.90 ± 2.11ᵃ | 11.33 ± 2.90ᵃ |
| WBC (mc mm⁻³) | 4210 ± 157ᵃ | 4157 ± 205ᵃ | 4001 ± 200ᵃ |
| RBC (mc mm⁻³) | 4.99 ± 1.10ᵃ | 5.10 ± 1.88ᵃ | 5.19 ± 1.50ᵃ |
| LYM (c µL⁻¹) | 83.00 ± 10ᵃ | 81.00 ± 8.0ᵃ | 83.00 ± 9.0ᵃ |

Values were expressed as mean ± SD (n=6); values along the row with the same superscript as the control are not statistically different at p<0.05 (student’s t-test); PVC = packed cell volume; Hb = hemoglobin; WBC = white blood cells; LYM = lymphocytes.

Table 2: Levels of the Liver Enzymes of Rats Treated with Wheat and Barley Diets

| Diet | ALP (U L⁻¹) | AST (U L⁻¹) | ALT (U L⁻¹) | TP (g dL⁻¹) | ALB (g dL⁻¹) |
|------|-------------|-------------|-------------|-------------|-------------|
| Control | 21.00 ± 1.00 | 11.67 ± 1.53 | 13.00 ± 1.00 | 7.00 ± 1.00 | 4.07 ± 1.53 |
| Barley | 17.67* ± 2.52 | 12.67 ± 2.52 | 07.67* ± 3.06 | 9.43* ± 2.41 | 3.73* ± 1.15 |
| Wheat | 15.33* ± 2.52 | 11.67 ± 1.53 | 07.33* ± 1.53 | 7.80* ± 1.72 | 4.06 ± 1.53 |

Values were expressed as Mean ± SD (n=6); values with an asterisk (*) on the same column are statistically different from control at p<0.05 (Student’s t-test). ALP = Alkaline Phosphatase; AST = Aspartate Amnion Transferase; ALT = Alanine Amino Transferase; TP = Total Protein; ALB = Albumin.

Table 3: Reproductive Performance of the Rats Fed Wheat and Barley Diets

| Diet | No of Reproductive Cycles in 60 Days | Offspring Per Birth | Offspring Survival Rate (%) |
|------|-----------------------------------|-------------------|---------------------------|
| Control | 1 | 8 | 90.00 |
| Barley | 1 | 9 | 89.91 |
| Wheat | 2 | 12 | 90.20 |
Plate 1: Photomicrograph of the Kidney Sections of the Control and Treated Rats (x 100)

Plate 2: Photomicrograph of the Heart Sections of the Control and Treated Rats (x 100)
Plate 3: Photomicrograph of the Liver Sections of the Control and Treated Rats (x 100)

Plate 4: Photomicrograph of the Ovary Sections of the Control and Treated rats (x 100)
Conclusion

The results obtained showed that the gluten-rich diets, wheat and barley did not adversely affect the histology as well as hematological and biochemical parameters of the treated rats at the evaluated days of study. This suggests that consumption of gluten-rich diets may not elicit harmful effects in biological systems. In addition, the study established a link between intakes of gluten-rich diets and enhanced reproductive performances. This was demonstrated by the increased number of the reproductive cycle completed by the wheat-fed rats and offspring per birth of both the wheat- and barley-fed rats. The protective role of gluten diets was also demonstrated in the normal offspring survival rates of the treated rats compared with the control. Collectively, the results showed that gluten-rich diets contain some health-boosting phytochemicals, vitamins, and minerals whose absence may initiate diseases in the body. This further suggests that the reported adverse effects of gluten consumption in some studies could be that the individuals were allergic or intolerant to gluten.
