Abstract

We prove that for the dyadic maximal operator $M$ and every locally integrable function $f \in L^1_{\text{loc}}(\mathbb{R}^d)$ with bounded variation, also $Mf$ is locally integrable and $\text{var} Mf \leq C_d \text{var} f$ for any dimension $d \geq 1$. It means that if $f \in L^1_{\text{loc}}(\mathbb{R}^d)$ is a function whose gradient is a finite measure then so is $\nabla Mf$ and $\|\nabla Mf\|_{L^1(\mathbb{R}^d)} \leq C_d \|\nabla f\|_{L^1(\mathbb{R}^d)}$.

We also prove this for the local dyadic maximal operator.

1 Introduction

Let $d \in \mathbb{N}$ and $\Omega$ be an open set in $\mathbb{R}^d$. For every locally integrable function $f \in L^1_{\text{loc}}(\Omega)$ we define the dyadic local maximal function by

$$M_\Omega f(x) = \sup_{x \in Q \subset \Omega, Q \subset \Omega} \frac{1}{\mathcal{L}(Q)} \int_Q f$$

where the supremum is taken over all dyadic cubes that contain $x$ and whose closure is contained in $\Omega$. With minor modifications we may also demand $Q$ or its interior to be contained in $\Omega$ instead, see Remark [14]. Various maximal operators have been investigated. The most well known are the uncentered Hardy-Littlewood maximal operator which averages over all balls centered in $x$, and the centered Hardy-Littlewood maximal operator which averages over all balls that contain $x$.

The regularity of a maximal operator was first studied in [17], where Kinnunen proved for the Hardy-Littlewood maximal operator that for $p > 1$ and $f \in W^{1,p}(\mathbb{R}^d)$ also the bound $\|\nabla Mf\|_p \leq C_{d,p} \|\nabla f\|_p$ holds, from which it follows that the Hardy-Littlewood maximal operator is bounded on $W^{1,p}(\mathbb{R}^d)$. His proof fails for $p = 1$. Note that also $\|\nabla Mf\|_1 \leq C_{d,1} \|\nabla f\|_1$ fails for any nonvanishing $f \in L^1(\mathbb{R}^d)$ because $Mf \in L^1(\mathbb{R}^d)$. So in 2004 Hajlasz and Onninen asked in [16] whether for $f \in W^{1,1}(\mathbb{R}^d)$ the Hardy-Littlewood maximal function satisfies $\nabla Mf \in L^1(\mathbb{R}^d)$ and $\|\nabla Mf\|_1 \leq C_d \|\nabla f\|_1$. This question for various maximal operators has become a well known problem and has been subject to lots of research, but has so far remained essentially unanswered in dimensions larger than one.

Here is the main result of this paper.

Key words and phrases. Maximal function, variation, dyadic cubes.
Theorem 1.1. Let $d \in \mathbb{N}$ and $\Omega$ be an open subset of $\mathbb{R}^d$. Let $f \in L^1_{\text{loc}}(\Omega)$ with $\text{var}_\Omega f < \infty$. Then $M_\Omega f \in L^1_{\text{loc}}(\Omega)$ and

$$\text{var}_\Omega M_\Omega f \leq C_d \text{var}_\Omega f$$

where $C_d$ depends only on $d$.

Note that we can for example take $\Omega = \mathbb{R}^d$. Theorem 1.1 answers the question of Hajlasz and Onninen for the dyadic maximal operator in the appropriate sense because it is clear that the gradient of the dyadic maximal function usually does not exist as a function in $L^1(\mathbb{R}^d)$. It also means that $\|\nabla Mf\|_p \leq C_{d,p} \|\nabla f\|_p$ does not make sense for any $p$ for the dyadic maximal operator. However for $p = 1$ it actually suffices also for the uncentered Hardy-Littlewood maximal operator to prove $\text{var} Mf \leq C_{d,p} \text{var} f$, because under this assumption $f \in W^{1,1}(\mathbb{R}^d)$ implies $\nabla Mf \in L^1(\mathbb{R}^d)$. This is due to Panu Lathi [21]. In this sense Theorem 1.1 is the first full answer to the question of Hajlasz and Onninen for any maximal operator in dimensions larger than one to the best of our knowledge.

In [27] we already proved Theorem 1.1 for characteristic functions for the dyadic and the uncentered Hardy-Littlewood maximal operator. This paper also makes use of Lemma 2.4 which is a variant of the relative isoperimetric inequality established in [27].

In one dimension for $L^1(\mathbb{R})$ the gradient bound has already been proven in [26] by Tanaka for the uncentered maximal function, and later in [20] by Kurka for the centered Hardy-Littlewood maximal function. The latter proof turned out to be much more complicated. In [3], Aldaz and Pérez Lázaro improved Tanaka’s bound to the sharp $\|\nabla Mf\|_{L^1(\mathbb{R})} \leq \|\nabla f\|_{L^1(\mathbb{R})}$ for the uncentered Hardy-Littlewood maximal function. In [15] Luiro has proven the gradient bound for the uncentered maximal operator for radial functions in $W^{1,1}(\mathbb{R}^d)$. In [2] Aldaz and Pérez Lázaro have done the same for block decreasing functions.

As a first step towards weak differentiability, Hajlasz and Malý proved in [15] that for $f \in L^1(\mathbb{R}^d)$ the centered Hardy-Littlewood maximal function is approximately differentiable. In [11] Aldaz, Colzani and Pérez Lázaro prove bounds on the modulus of continuity for all dimensions. A related question is whether the maximal operator is a continuous operator. Luiro proves in [22] that for $p > 1$ the uncentered maximal operator is continuous on $W^{1,p}(\mathbb{R}^d)$. There is ongoing research for the endpoint case $p = 1$. For example Carneiro, Madrid and Pierce proved in [11] that for the uncentered maximal function $f \mapsto \nabla Mf$ is continuous $W^{1,1}(\mathbb{R}) \to L^1(\mathbb{R})$.

The regularity of maximal operators has also been studied on other spaces and for other maximal operators. We focus on the endpoint $p = 1$. For example in [12] Carneiro and Svaiter and in [8] Carneiro and González-Riquelme consider convolution maximal operators associated to certain partial differential equations. They prove $\|\nabla Mf\|_{L^1(\mathbb{R}^d)} \leq C_d \|\nabla f\|_{L^1(\mathbb{R}^d)}$ for $d = 1$, and for $d > 1$ if $f$ is radial. In [9] Carneiro and Hughes proved the discrete result $\|\nabla Mf\|_{l^1(\mathbb{Z}^d)} \leq C_d \|f\|_{l^1(\mathbb{Z}^d)}$ for centered and uncentered maximal operators. This bound does not hold on $\mathbb{R}^d$ but is weaker than the yet unknown $\|\nabla Mf\|_{l^1(\mathbb{Z}^d)} \leq C_d \|\nabla f\|_{l^1(\mathbb{Z}^d)}$, due to $\|\nabla f\|_{l^1(\mathbb{Z}^d)} \leq C_d \|f\|_{l^1(\mathbb{Z}^d)}$. In [19] Kinnunen and Tuominen work in the metric setting. They prove the boundedness of a discrete maximal operator in the H"{a}l"{a}sz Sobolev space $M^{1,1}$. In [25] Prez, Picon, Saari and Sousa consider Hardy-Sobolev spaces instead of Sobolev spaces. They prove the boundedness of certain convolution maximal operators on $H^{1,p}$ for a sharp range of exponents, including $p = 1$. The study of the regularity of the fractional maximal operators was initiated by Kinnunen and Saksman in [18]. It does not map from $L^p(\mathbb{R}^d)$ to $L^p(\mathbb{R}^d)$ but the exponent changes, so also the endpoint question, formulated in [10], looks a little different. It remains unanswered, but there is partial progress, similarly as for the Hardy-Littlewood maximal operator; see for example [6, 9, 10, 24]. For more background
information on the regularity of maximal operators there is a survey \cite{Carneiro} by Carneiro.

The dyadic maximal operator has enjoyed a bit less attention than its continuous counterparts, such as the centered and the uncentered Hardy-Littlewood maximal operator. Dyadic cubes are usually way easier to deal with than balls, but the dyadic version still serves as a model case for the continuous versions since they share many properties. A classical example is the Hardy-Littlewood maximal inequality, where the proofs are identical for both types of maximal operators, after the Vitali Covering Lemma is applied for the continuous version, which however is the most complicated part of the proof. The most recent example is \cite{27}, which proves $\text{var } M1_E \leq C_d \text{var } 1_E$ for the dyadic maximal operator and the uncentered Hardy-Littlewood maximal operator. The proof for the dyadic maximal operator is much easier, but the same proof strategy also works for the uncentered maximal operator. But similar to the above example, the tools used make that strategy work are more involved than the strategy in the first place. Therefore this paper may raise hope that the variation boundedness also holds for continuous maximal operators. For the centered Hardy-Littlewood maximal operator another strategy would be necessary though, because both the proofs in \cite{27} and here rely on the fact that the levels sets $\{Mf > \lambda\}$ of the maximal functions can be written as the union of all balls/dyadic cubes $X$ with $\int_X f > \lambda \mathcal{L}(X)$, which does not hold for the centered Hardy-Littlewood maximal function.

For $f \in L^1_{\text{loc}}(\Omega)$ it already follows from well-known theory that $M_{\Omega}f \in L^1_{\text{loc}}(\Omega)$. We state it in Theorem 1.1 because it is a prerequisite to define the variation of $M_{\Omega}f$. Define $L^1_{\text{loc}}(\Omega)$ to be the set of all functions $f$ such that for each measurable and bounded set $U$ we have that $\int_U |f|$ is finite. Note that $L^1_{\text{loc}}(\Omega) \subset L^1_{\text{loc}}(\Omega)$. For $f \in L^1_{\text{loc}}(\Omega)$ define

$$\tilde{M}_{\Omega}f(x) = \sup_{x \in Q, Q \subset \Omega} \frac{1}{\mathcal{L}(Q)} \int_Q f.$$  

For local maximal operators such as $\tilde{M}_{\Omega}$, $L^1_{\text{loc}}(\Omega)$ is not the correct domain of definition because $f \in L^1_{\text{loc}}(\Omega)$ does not imply that $M_{\Omega}f$ is finite almost everywhere. This has already been observed in footnote (2) of \cite[p. 170]{16}. Instead the following variant of Theorem 1.1 holds true.

**Theorem 1.2.** Let $f \in L^1_{\text{loc}}(\Omega)$ with $\text{var } f < \infty$. Then $\tilde{M}_{\Omega}f \in L^1_{\text{loc}}(\Omega)$ and

$$\text{var } \tilde{M}_{\Omega}f \leq C_d \text{var } f.$$

**Remark 1.3.** Theorem 1.1 and Theorem 1.2 also extend to the maximal function of the absolute value due to $\text{var } M_{\Omega}(|f|) \leq C_d \text{var } |f| \leq C_d \text{var } f$.

Typically, the maximal operator integrates over $|f|$ instead of $f$. That is because traditionally the maximal function is used for $L^p$ estimates for which the absolute value of a function matters. However here we are looking at regularity properties and didn’t see a major reason to restrict like that.

**Remark 1.4.** As will be visible from the proof, Theorem 1.1 and Theorem 1.2 actually hold for all maximal operators of the form

$$Mf(x) = \sup_{x \in Q, Q \subset \Omega} \frac{1}{\mathcal{L}(Q)} \int_Q f,$$

where $Q$ is a collection of dyadic cubes $Q$ with $\overline{Q} \subset \Omega$ or $\hat{Q} \subset \Omega$ respectively, and $f$ is such that $Mf \geq f$ a.e. in $\Omega$. The constant is the same as in Theorem 1.1, in particular it only depends on $d$.  

3
Remark 1.5. The discrete version of Theorem 1.1 also holds on \( \mathbb{Z}^d \). This is a consequence of the correspondence between a function \( f \) on \( \mathbb{Z}^d \) and \( \hat{f} = \sum_{z \in \mathbb{Z}^d} f(z) 1_{[0,1]^d} \) on \( \mathbb{R}^d \).

The main step towards the proof of Theorem 1.1 is the following finite version.

**Proposition 1.6.** Let \( Q \) be a finite set of dyadic cubes which contains all parents of cubes in \( Q \) that lie within \( \bigcup_{Q \in Q} Q \subset \Omega \). Let \( \Omega \) be open with \( \bigcup_{Q \in Q} \hat{Q} \subset \Omega \). Let \( f \in L^1(\Omega) \) and denote

\[
M_Q f(x) = \max \left\{ f(x), \frac{1}{L(Q)} \int_Q f : x \in Q \in Q \right\}.
\]

Then

\[
\text{var}_\Omega M_Q f \leq C_d \text{var}_\Omega f. \tag{1}
\]

We first prove Proposition 1.6 because it allows us to set aside convergence issues. In the proof of Theorem 1.1 we only use Proposition 1.6 with \( \Omega = \bigcup_{Q \in Q} \hat{Q} \).

**Remark 1.7.** In Proposition 1.6 we could also prove \( \text{var}_U M_Q f \leq C_d \text{var}_U f \) for any Borel set \( U \subset \Omega \) with \( \bigcup_{Q \in Q} \hat{Q} \subset U \) because as noted in [4, Theorem 3.40], the corea formula Lemma 2.1 also holds for Borel sets.

I would like to thank my supervisor, Juha Kinnunen for all of his support, Panu Lahti for repeated reading of and advice on the manuscript, and Olli Saari for his idea on how to prove \( M_{\Omega} f \in L^1_{\text{loc}}(\Omega) \) more quickly. The author has been supported by the Vilho, Yrjö and Kalle Väisälä Foundation of the Finnish Academy of Science and Letters.

## 2 Setup

We work in the setting of sets of functions of bounded variation, as in Evans-Gariepy [13], Section 5. For an open set \( \Omega \subset \mathbb{R}^d \), a function \( f \in L^1_{\text{loc}}(\Omega) \) is said to have locally bounded variation if for each open and compactly supported \( V \subset \Omega \) we have

\[
\sup \left\{ \int_V f \div \varphi : \varphi \in C^1_c(V; \mathbb{R}^d), |\varphi| \leq 1 \right\} < \infty.
\]

Such a function comes with a measure \( \mu \) and a function \( \nu : \Omega \to \mathbb{R}^d \) that has \( |\nu| = 1 \) \( \mu \)-a.e. such that for all \( \varphi \in C^1_c(\Omega; \mathbb{R}^d) \) we have

\[
\int_V f \div \varphi = \int_V \varphi \nu \, d\mu.
\]

We define the variation of \( f \) in \( \Omega \) by

\[
\text{var}_\Omega f = \mu(\Omega).
\]

Recall the definition of the set of dyadic cubes

\[
\bigcup_{n \in \mathbb{Z}} \{ [x_1, x_1 + 2^n) \times \ldots \times [x_d, x_d + 2^n) : i = 1, \ldots, n, x_i \in 2^n \mathbb{Z} \}.
\]

For a dyadic cubes \( Q \) denote by \( l(Q) \) the sidelength of \( Q \). For a locally integrable function \( f \) denote

\[
f_Q = \int_Q f = \frac{1}{L(Q)} \int_Q f.
\]
For a set $Q$ of dyadic cubes denote 
\[ \bigcup Q = \bigcup_{Q \in Q} Q \]
as is commonly used in set theory. By $a \lesssim b$ we mean that there exists a constant $C_d$ that depends only on the dimension $d$ such that $a \leq C_d b$. For a measurable set $E \subset \mathbb{R}^d$ we define the measure theoretic boundary by
\[ \partial E = \{ x : \limsup_{r \to 0} \frac{\mathcal{L}(B(x, r) \setminus E)}{r^d} > 0, \limsup_{r \to 0} \frac{\mathcal{L}(B(x, r) \cap E)}{r^d} < 0 \} \]
and the measure theoretic closure by
\[ \overline{E} = \{ x : \limsup_{r \to 0} \frac{\mathcal{L}(B(x, r) \cap E)}{r^d} > 0 \} \].

We denote the topological interior, boundary and closure by $\overset{\circ}{E}$, $\partial E$, $E$. Note that for finite unions of cubes the measure theoretic boundary, closure and interior agree with the respective topological quantities.

As in [27], our approach to the variation is the the coarea formula.

**Lemma 2.1** (Theorem 3.40 in [4]). Let $\Omega \subset \mathbb{R}^d$ be open. Let $f \in L^1_{\text{loc}}(\Omega)$. Then
\[ \text{var}_\Omega f = \int_\mathbb{R} \mathcal{H}^{d-1}(\partial_s \{ f > \lambda \} \cap \Omega) \, d\lambda. \]

We need the following elementary decomposition of the measure theoretic boundary of the union of two sets.

**Lemma 2.2** (Lemma 1.7 in [27]). Let $A, B \subset \mathbb{R}^d$ be measurable. Then
\[ \partial_s (A \cup B) \subset \partial_s A \setminus \overline{E} \cup \partial_s B \setminus \overline{E} \cup (\partial_s A \cap \partial_s B). \]

The proof of Lemma 2.2 is straightforward and can be found in [27].

A central tool is the relative isoperimetric inequality. In Theorem 5.11 in [13] it is stated for balls, but it also holds for cubes, see Theorem 107 in [14].

**Lemma 2.3.** Let $Q, E \subset \mathbb{R}^d$ be a cube and a measurable set with $\mathcal{L}(E \cap Q) \leq \frac{1}{2} \mathcal{L}(Q)$. Then
\[ \mathcal{L}(E \cap Q)^{d-1} \lesssim \mathcal{H}^{d-1}(\partial_s E \cap Q)^d. \]

The following result from [27] is closely related to the relative isoperimetric inequality.

**Lemma 2.4** (Proposition 3.1 in [27]). Let $E \subset \mathbb{R}^d$ be measurable and $Q$ a cube (or a ball) with $\mathcal{L}(E \cap Q) = \lambda \mathcal{L}(Q)$. Then
\[ \mathcal{H}^{d-1}(\partial Q \setminus E) \lesssim \lambda^{-\frac{d-1}{d}} \mathcal{H}^{d-1}(\partial_s E \cap Q). \]

In the proof of Proposition 1.6 we split the variation of $M_Q f$ into two pieces. One piece can be bounded using Lemma 2.4. Bounding the second piece is the main contribution of this paper. We formulate it as follows.
Proposition 2.5. Let $f$ and $Q$ be as in Proposition 1.6. For each $\lambda \in \mathbb{R}$ let $Q_\lambda$ be the set of maximal cubes of $\{Q \in Q : f_Q > \lambda\}$. Then

$$\sum_{Q \in Q} \int_{\lambda : Q \in Q_\lambda, \mathcal{L}(Q \cap \{f > \lambda\}) < 2^{-d - 2} \mathcal{L}(Q)} \mathcal{H}^{d-1}(\partial Q) d\lambda \lesssim \text{var}_{\bigcup \{Q : Q \in Q\}} f$$

Proof of Proposition 1.6. For each $\lambda$, denote by $Q_\lambda$ the set of maximal cubes in $Q$ with $f_Q > \lambda$. Then $Q_\lambda$ consists of disjoint cubes and

$$\{M_Q f > \lambda\} = \bigcup Q_\lambda \cup \{f > \lambda\}.$$

By Lemmas 2.1 and 2.2 we get

$$\text{var}_\Omega M_Q f = \int_{-\infty}^\infty \mathcal{H}^{d-1}(\partial \{M_Q f > \lambda\} \cap \Omega) d\lambda$$

$$= \int_{-\infty}^\infty \mathcal{H}^{d-1}(\partial \big(\bigcup Q_\lambda \cup \{f > \lambda\}\big) \cap \Omega) d\lambda$$

$$\leq \int_{-\infty}^\infty \mathcal{H}^{d-1}(\partial \big(\bigcup Q_\lambda \setminus \{f > \lambda\}\big) \cap \Omega) d\lambda + \mathcal{H}^{d-1}(\partial \{f > \lambda\} \cap \Omega) d\lambda$$

$$\leq \int_{-\infty}^\infty \mathcal{H}^{d-1}(\partial \big(\bigcup Q_\lambda \setminus \{f > \lambda\}\big)) d\lambda + \text{var}_\Omega f.$$

It remains to estimate the first summand. We split it into two parts.

$$\int_{-\infty}^\infty \mathcal{H}^{d-1}(\partial \big(\bigcup Q_\lambda \setminus \{f > \lambda\}\big)) d\lambda \leq \int_{-\infty}^\infty \sum_{Q \in Q} \mathcal{H}^{d-1}(\partial Q \setminus \{f > \lambda\}) d\lambda$$

$$= \sum_{Q \in Q} \int_{\lambda : Q \in Q_\lambda} \mathcal{H}^{d-1}(\partial Q \setminus \{f > \lambda\}) d\lambda$$

$$= \sum_{Q \in Q} \int_{\lambda : Q \in Q_\lambda, \mathcal{L}(Q \cap \{f > \lambda\}) \geq 2^{-d - 2} \mathcal{L}(Q)} \mathcal{H}^{d-1}(\partial Q \setminus \{f > \lambda\}) d\lambda$$

$$+ \sum_{Q \in Q} \int_{\lambda : Q \in Q_\lambda, \mathcal{L}(Q \cap \{f > \lambda\}) < 2^{-d - 2} \mathcal{L}(Q)} \mathcal{H}^{d-1}(\partial Q \setminus \{f > \lambda\}) d\lambda.$$

The second summand in the previous display is bounded by Proposition 2.5. The first summand can be bounded using Lemma 2.3.

$$\sum_{Q \in Q} \int_{\lambda : Q \in Q_\lambda, \mathcal{L}(Q \cap \{f > \lambda\}) \geq 2^{-d - 2} \mathcal{L}(Q)} \mathcal{H}^{d-1}(\partial Q \setminus \{f > \lambda\}) d\lambda$$

$$\lesssim \sum_{Q \in Q} \int_{\lambda : Q \in Q_\lambda, \mathcal{L}(Q \cap \{f > \lambda\}) \geq 2^{-d - 2} \mathcal{L}(Q)} \mathcal{H}^{d-1}(\partial \{f > \lambda\} \cap Q) d\lambda$$

$$\leq \int_{-\infty}^\infty \sum_{Q \in Q_\lambda} \mathcal{H}^{d-1}(\partial \{f > \lambda\} \cap \hat{Q}) d\lambda.$$
\[
\leq \int_{-\infty}^{\infty} \mathcal{H}^{d-1}(\partial \{f > \lambda\} \cap \bigcup \{Q : Q \in Q\}) \, d\lambda \\
= \text{var}_{\bigcup \{\hat{Q} : Q \in Q\}} f
\]

3 Proof of Proposition 2.5

For a set \(Q\), a dyadic cube \(Q\) and \(r, \lambda \geq 0\) abbreviate the statement

\[Q\text{ is a maximal dyadic cube of } \{P : f_P > \lambda\},\]

which also satisfies \(\mathcal{L}(\{f > \lambda\} \cap Q) < r \mathcal{L}(Q)\)

by \(\varphi(Q, Q, \lambda, r)\). Then Proposition 2.5 claims

\[
\sum_{Q \in Q} \hat{\int}_{\lambda_0}^{\infty} \mathcal{H}^{d-1}(\partial Q) \, d\lambda \lesssim \text{var} f.
\]

Proposition 3.1. Let \(Q_0\) be a dyadic cube, \(\lambda_0 \in \mathbb{R}\) and \(f \in L^1(Q_0)\) with \(\mathcal{L}(\{f > \lambda_0\} \cap Q_0) \leq 2^{-d-1} \mathcal{L}(Q_0)\). Then

\[
\mathcal{L}(Q_0)(f_{Q_0} - \lambda_0) \leq 2^{d+1} \int_{\lambda_0}^{\infty} \sum_{P : \varphi(P, 2^{-d-2}, \lambda_0, 1/2)} \mathcal{L}(P \cap \{f > \lambda\}) \, d\lambda.
\]

Proof. For each \(\lambda \in \mathbb{R}\) denote by \(Q_\lambda\) the set of all maximal cubes \(Q \subset Q_0\) with \(f_{Q} > \lambda\). Recall that

\[
\int_{\lambda_0}^{\infty} \mathcal{L}(\{f > \lambda\}) \, d\lambda = \int_{\lambda_0}^{\infty} \mathcal{L}(\{f > \lambda\} \cap \bigcup Q_\lambda) \, d\lambda.
\]

(2)

Let \(Q\) be the set of dyadic cubes \(Q \subset Q_0\) with \(f_{Q} \leq \lambda_0\) or \(\mathcal{L}(\{f > f_{Q}\} \cap Q) > 2^{-d-1} \mathcal{L}(Q)\) and denote by \(\hat{Q}\) the set of maximal cubes of \(Q\). Then

\[
\int_{\lambda_0}^{\infty} \mathcal{L}(\{f > \lambda\} \cap \bigcup Q) \, d\lambda - \int_{-\infty}^{\lambda_0} \mathcal{L}(\{f < \lambda\} \cap \bigcup Q) \, d\lambda
\]

\[
= \sum_{Q \in \hat{Q}} \int_{\lambda_0}^{\infty} \mathcal{L}(\{f > \lambda\} \cap Q) \, d\lambda - \int_{-\infty}^{\lambda_0} \mathcal{L}(\{f < \lambda\} \cap Q) \, d\lambda
\]

\[
= \sum_{Q \in \hat{Q}} \mathcal{L}(Q)(f_{Q} - \lambda_0)
\]

\[
\leq \sum_{Q \in \hat{Q}, f_{Q} > \lambda_0} \mathcal{L}(Q)(f_{Q} - \lambda_0)
\]

\[
\leq 2^{d+1} \sum_{Q \in \hat{Q}, f_{Q} > \lambda_0} \mathcal{L}(\{f > f_{Q}\} \cap Q)(f_{Q} - \lambda_0)
\]

\[
\leq 2^{d+1} \sum_{Q \in \hat{Q}, f_{Q} > \lambda_0} \int_{\lambda_0}^{f_{Q}} \mathcal{L}(\{f > \lambda\} \cap Q) \, d\lambda
\]
\[ = 2^{d+1} \int_{\lambda_0}^{\infty} \mathcal{L} \left( \bigcup_{Q \in \tilde{Q}, f_Q \geq \lambda} \{ f > \lambda \} \cap Q \right) d\lambda. \]

By (3) and (2) we get

\[ (f_{Q_0} - \lambda_0) \mathcal{L}(Q_0) = \int_{\lambda_0}^{\infty} \mathcal{L}(\{ f > \lambda \}) d\lambda - \int_{-\infty}^{\lambda_0} \mathcal{L}(\{ f < \lambda \}) d\lambda \]
\[ + \int_{\lambda_0}^{\infty} \mathcal{L}(\{ f > \lambda \} \setminus \bigcup Q) d\lambda - \int_{-\infty}^{\lambda_0} \mathcal{L}(\{ f < \lambda \} \setminus \bigcup Q) d\lambda \]
\[ \leq 2^{d+1} \int_{\lambda_0}^{\infty} \mathcal{L} \left( \bigcup_{Q \in \tilde{Q}, f_Q \geq \lambda} \{ f > \lambda \} \cap Q \right) d\lambda + \int_{\lambda_0}^{\infty} \mathcal{L}(\{ f > \lambda \} \setminus \bigcup Q) d\lambda \]
\[ \leq 2^{d+1} \int_{\lambda_0}^{\infty} \mathcal{L}(\{ f > \lambda \} \setminus \bigcup \tilde{Q} \cup \bigcup_{Q \in \tilde{Q}, f_Q \geq \lambda} \{ f > \lambda \} \cap Q) d\lambda \]
\[ = 2^{d+1} \int_{\lambda_0}^{\infty} \mathcal{L}(\{ f > \lambda \} \setminus \bigcup \{ Q \in \tilde{Q}, f_Q < \lambda \}) d\lambda \]
\[ = 2^{d+1} \int_{\lambda_0}^{\infty} \mathcal{L}(\{ f > \lambda \} \setminus \bigcup \tilde{Q} \cup \bigcup_{Q \in \tilde{Q}, f_Q < \lambda} \{ f > \lambda \} \cap Q) d\lambda \]
\[ \leq 2^{d+1} \int_{\lambda_0}^{\infty} \mathcal{L}(\{ f > \lambda \} \cap \bigcup \{ Q \in \tilde{Q} : \exists P \in \tilde{Q} \cap Q \}) d\lambda \]
\[ = 2^{d+1} \int_{\lambda_0}^{\infty} \sum_{Q \in \tilde{Q}, P \in Q : Q \subseteq P} \mathcal{L}(\{ f > \lambda \} \cap Q) d\lambda. \]

It remains to show that if \( Q \in \tilde{Q} \lambda \) such that for all \( P \in \tilde{Q} \) we do not have \( Q \subseteq P \), then \( \mathcal{L}(\{ f > f_Q \} \cap Q) \leq \mathcal{L}(Q)/2 \). If \( Q = Q_0 \) then this is true by assumption. If \( Q \not\subseteq Q_0 \) then the dyadic parent \( P \) of \( Q \) is contained in \( Q_0 \) and not in \( \tilde{Q} \). Therefore

\[ \mathcal{L}(\{ f > f_Q \} \cap Q) \leq \mathcal{L}(\{ f > f_Q \} \cap P) \]
\[ \leq \mathcal{L}(\{ f > f_P \} \cap P) \]
\[ \leq 2^{-d-1} \mathcal{L}(P) \]
\[ = \frac{\mathcal{L}(Q)}{2}. \]

\[ \square \]

**Corollary 3.2.** Let \( Q_0 \) be a dyadic cube, \( \lambda_0 \in \mathbb{R} \) and \( f \in L^1(Q_0) \) with \( \mathcal{L}(\{ f > \lambda_0 \} \cap Q_0) \leq 2^{-d-2} \mathcal{L}(Q_0) \). Then

\[ \mathcal{L}(Q_0) (f_{Q_0} - \lambda_0) \leq 2^{d+2} \int_{f_{Q_0}}^{\infty} \sum_{P : P \cap (Q_{2^q Q_0, \lambda, 1/2})} \mathcal{L}(P \cap \{ f > \lambda \}) d\lambda. \]
Proof. We have
\[
\int_{\lambda_0}^{f_Q} \mathcal{L}\{f < \lambda\} \cap Q_0 \, d\lambda \leq \int_{\lambda_0}^{f_Q} 2^{-d-2} \mathcal{L}(Q_0) \, d\lambda = 2^{-d-2} \mathcal{L}(Q_0)(f_{Q_0} - \lambda_0).
\]
so that we get
\[
\mathcal{L}(Q_0)(f_{Q_0} - \lambda_0) \leq 2 \left[ \mathcal{L}(Q_0)(f_{Q_0} - \lambda_0) - 2^{d+1} \int_{\lambda_0}^{f_Q} \mathcal{L}\{f > \lambda\} \cap Q_0 \, d\lambda \right].
\]
Since \(\mathcal{L}\{f > \lambda_0\} \cap Q_0 \leq 2^{-d-2} \mathcal{L}(Q_0) < 2^{-d-1} \mathcal{L}(Q_0)\) we can apply Proposition 3.1 to estimate \(\mathcal{L}(Q_0)(f_{Q_0} - \lambda_0)\) on the right hand side of the previous display and obtain
\[
\mathcal{L}(Q_0)(f_{Q_0} - \lambda_0) \leq 2 \left[ 2^{d+1} \int_{\lambda_0}^{\infty} \sum_{P: \varphi(P, 2^d Q, f, \lambda_0)} \mathcal{L}\{f > \lambda\} \cap P \, d\lambda - 2^{d+1} \int_{\lambda_0}^{f_Q} \mathcal{L}\{f > \lambda\} \cap Q_0 \, d\lambda \right]
\]
\[
\leq 2^{d+2} \int_{f_{Q_0}}^{\infty} \sum_{P: \varphi(P, 2^d Q, f, \lambda_0)} \mathcal{L}\{f > \lambda\} \cap P \, d\lambda.
\]
And we need a short argument.

Lemma 3.3. Let \(Q\) be a set of dyadic cubes which contains all parents of cubes in \(Q\) that lie within \(Q\). Let \(P, Q, \mu, \lambda\) with \(\varphi(Q, Q, \mu, 2^{-d-2}), f_Q < \lambda < f_P\) and \(\varphi(P, 2^d Q, \lambda, \frac{1}{2})\). Then \(\varphi(P, 2^d Q, \lambda, \frac{1}{2})\) and \(Q \supset P\).

Note that \(\varphi(P, 2^d Q, \lambda, \frac{1}{2})\) is not the same as \(\varphi(P, Q, \lambda, \frac{1}{2})\). The difference is that \(2^d Q\) also contains all ascendants of the dyadic cubes in \(Q\). The assumption on \(Q\) however says that all ancestors \(P\) of dyadic cubes \(Q \in Q\) that are in \(2^d Q\) are also in \(Q\).

Proof of Lemma 3.3. Note that \(\mu < f_Q < \lambda\). \(P \subset Q\) follows from \(\varphi(P, 2^d Q, \lambda, \frac{1}{2})\). From \(\varphi(Q, Q, \mu, 2^{-d-2})\) and the assumption on \(Q\) we get that there is no cube \(P\) in \(\bigcup Q\) other than \(Q\) that contains \(Q\) and has \(f_P > \lambda\). Thus all such maximal \(P \subset \bigcup Q\) with \(f_P > \lambda\) that touch \(Q\) have to be contained in \(Q\). This means from \(\varphi(P, 2^d Q, \lambda, \frac{1}{2})\) we can conclude \(\varphi(P, 2^d Q, \lambda, \frac{1}{2})\).

Proof of Proposition 2.5 Recall that for \(\mu \in \mathbb{R}, Q_{\mu}\) is the set of all maximal cubes of \(\{Q \in Q : f_Q > \mu\}\). Let \(Q \in Q\) and assume there is a \(\mu \in \mathbb{R}\) with \(Q \in Q_{\mu}\) and \(\mathcal{L}(Q \cap \{f > \mu\}) < 2^{-d-2} \mathcal{L}(Q)\). Then for
\[
\lambda_Q = \max \left\{ \inf \{\lambda : \mathcal{L}\{f > \lambda\} \cap Q < 2^{-d-2} \mathcal{L}(Q)\}, \max \{f_P : P \in Q, Q \subset P\} \right\}
\]
we have \(\lambda_Q < f_Q\) and \(Q\) and \(\lambda_Q\) satisfy the premise of Corollary 3.2 Therefore
\[
\int_{\mu : Q \in Q_{\mu}, \mathcal{L}(Q \cap \{f > \mu\}) < 2^{-d-2} \mathcal{L}(Q)} \mathcal{H}^{d-1}(\partial \mu) \, d\mu = (f_Q - \lambda_Q) \mathcal{H}^{d-1}(\partial Q)
\]
\[
\leq \frac{2^{d+2}}{l(Q)} \int_{f_Q}^{\infty} \sum_{P: \varphi(P, 2^d Q, f, \lambda_0)} \mathcal{L}\{f > \lambda\} \cap P \, d\lambda.
\]
and we get
\[
\sum_{Q \in \mathcal{Q}} \int_{\mu : Q \in \mathcal{Q}_\mu} \mathcal{L}(Q \cap \{f > \mu\}) < 2^{-d-2} \mathcal{L}(Q) \, \mathcal{H}^{d-1}(\partial Q) \, d\mu \\
\leq 2^{d+2} \int_0^\infty \sum_{Q : \exists \mu > 0 \varphi(Q, \mathcal{Q}, \mu, 2^{-d-2}), \lambda > \mu, f} \left( \sum_{P : \varphi(P, 2^Q, \lambda, 1/2)} \frac{\mathcal{L}(\{f > \lambda\} \cap P)}{l(Q)} \right) \, d\lambda.
\]

Lemma 3.3 says that we can rearrange the sums as follows
\[
\sum_{Q : \exists \mu > 0 \varphi(Q, \mathcal{Q}, \mu, 2^{-d-2}), \lambda > \mu, f} \left( \sum_{P : \varphi(P, 2^Q, \lambda, 1/2)} \frac{\mathcal{L}(\{f > \lambda\} \cap P)}{l(Q)} \right) \leq \sum_{P : \varphi(P, 2^Q, \lambda, 1/2)} \sum_{Q \supset P} \frac{\mathcal{L}(\{f > \lambda\} \cap P)}{l(Q)}.
\]

Further note that
\[
\sum_{Q \supset P} \frac{1}{l(Q)} \leq 2 \frac{1}{l(P)}
\]

and that by \(\mathcal{L}(\{f > \lambda\} \cap P) \leq \mathcal{L}(P)/2\) and Lemma 2.3 we have
\[
\frac{\mathcal{L}(\{f > \lambda\} \cap P)}{l(P)} \leq \mathcal{L}(\{f > \lambda\} \cap P)^{1 - \frac{d}{2}} \lesssim \mathcal{H}^{d-1}(\partial \{f > \lambda\} \cap P).
\]

Combining the previous four displays we can conclude
\[
\sum_{Q \in \mathcal{Q}} \int_{\mu : Q \in \mathcal{Q}_\mu} \mathcal{L}(Q \cap \{f > \mu\}) < 2^{-d-2} \mathcal{L}(Q) \, \mathcal{H}^{d-1}(\partial Q) \, d\mu \\
\leq \int_0^\infty \sum_{P : \varphi(P, 2^Q, \lambda, 1/2)} \mathcal{H}^{d-1}(\partial \{f > \lambda\} \cap P) \, d\lambda \\
\leq \int_0^\infty \mathcal{H}^{d-1}(\partial \{f > \lambda\} \cap \bigcup \{\hat{Q} : Q \in \mathcal{Q}\}) \, d\lambda \\
= \text{var}_{\{\hat{Q}, Q \in \mathcal{Q}\}} f.
\]

This finishes the proof. \(\square\)

4 Approximating the full maximal operator

We need an approximation result to conclude Theorem 1.1 from Proposition 1.6.

Lemma 4.1 (Theorem 5.2 in [13]). Let \(\Omega \subset \mathbb{R}^d\) be an open set and \(f \in L^1_{\text{loc}}(\Omega)\). Let \((f_n)\) be a sequence functions that converges to \(f\) in \(L^1_{\text{loc}}(\Omega)\). Then
\[
\text{var}_\Omega f \leq \liminf_{n \to \infty} \text{var}_\Omega f_n.
\]

Proposition 4.2. Let \(\Omega\) be open and \(f \in L^1_{\text{loc}}(\Omega)\) with \(\text{var}_\Omega f < \infty\). Then
\[
\int_{\mathbb{R}^d} \mathcal{H}^{d-1}(\partial_x \{x \in \Omega : M_\Omega f > \lambda\}) \lesssim \text{var}_\Omega f.
\]

The same holds true for \(f \in L^1_{\text{loc}}(\Omega)\) and \(\tilde{M}_\Omega f\).
Proposition 4.2 is almost Theorem 1.1. But we also need $M_{\Omega} f \in L^1_{\text{loc}}(\Omega)$ to invoke the coarea formula Lemma 2.1.

Proof of Proposition 4.2. We write down the proof of Proposition 4.2 formally for $M_{\Omega}$. For the proof for $\tilde{M}_{\Omega}$ just replace $M_{\Omega}$ by $\tilde{M}_{\Omega}$.

Take an enumeration $Q_1, Q_2, \ldots$ of all dyadic cubes whose closure/interior is contained in $\Omega$, and such that for each $n \in \mathbb{N}$, each dyadic cube $Q \subset Q_1 \cup \ldots \cup Q_n$ that contains a cube in $\{Q_1, \ldots, Q_n\}$ already belongs to $\{Q_1, \ldots, Q_n\}$. Denote $Q^n = \{Q_1, \ldots, Q_n\}$. Then $(\bigcup Q^n)_n$ is an increasing sequence of sets. Since $\Omega$ is open we have

$$\bigcup_{n} Q^n = \Omega.$$ 

For a function $g$ and $N \in \mathbb{N}$ denote the truncation of $g$ by $g_N(x) = \min \{ \max \{ g(x), -N \}, N \}$. Then for each $N \in \mathbb{N}$ we have $M_{\Omega} f_N \in L^1_{\text{loc}}(\Omega)$. Thus by Lemma 2.1

$$\hat{R} H^d - 1(\partial^* \{ x \in \Omega : M_{\Omega} f > \lambda \}) = \lim_{N \to \infty} \hat{N} H^d - 1(\partial^* \{ x \in \Omega : M_{\Omega} f > \lambda \})$$

$$= \lim_{N \to \infty} \var_{\Omega} M_{\Omega} f^N$$

$$= \lim_{N \to \infty} \lim \var_{\bigcup Q_n} M_{\Omega} f^N.$$ 

Furthermore $M_{\Omega} f^N$ is the pointwise supremum of the set of countable functions $(\overline{f_{Q_n}})_n$ and $M_{\Omega} f^N \geq \overline{f}^N$ a.e. on $\Omega$. Thus by monotone convergence $M_{\Omega} f^N$ converges to $M_{\Omega} f^N$ in $L^1_{\text{loc}}(\Omega)$ for $k \to \infty$, and hence for each $n$ in $L^1(\bigcup Q^n)$. Thus by Lemma 4.1

$$\var_{\bigcup Q_k} M_{\Omega} f^N \leq \liminf_{k \to \infty} \var_{\bigcup Q_k} M_{\Omega} f^N$$

$$\leq \liminf_{k \to \infty} \var_{\bigcup Q_k} M_{\Omega} f.$$ 

In the setting of $M_{\Omega}$ we have that $\bigcup Q_k$ is compactly contained in $\Omega$. Thus $f \in L^1(\bigcup Q_k)$. In the setting of $\tilde{M}_{\Omega}$ we have $f \in \tilde{M}_{\text{loc}}^1(\Omega)$ so that $f \in L^1(\bigcup Q_k)$ follows from $\bigcup Q_k$ being bounded. Thus in both settings we can invoke Proposition 1.11 and get

$$\var_{\bigcup Q_k} M_{\Omega} f \lesssim \var_{\Omega} f,$$

which finishes the proof. 

4.1 Membership of $L^1_{\text{loc}}(\Omega)$

Lemma 4.3. Let $Q_1, Q_2, \ldots$ be an increasing sequence of cubes and denote by $Q_\infty$ the quadrant $Q_1 \cup Q_2 \cup \ldots$. Let $f \in L^1_{\text{loc}}(Q_\infty)$ with $f \geq 0$, $\int_{Q_1} f < \infty$ and $\var_{Q_\infty} f < \infty$. Then

$$\lim_{n \to \infty} \sup_{Q_n} f_{Q_n} < \infty.$$
Proof. Since \( f_Q < \infty \) it suffices to bound \( |f_Q_n - f_Q| \) independent of \( n \). By the triangle inequality and by Poincaré’s inequality

\[
|f_Q_n - f_Q| \leq \mathcal{L}(Q)\frac{d-1}{d} \|f - f_Q\|_{L^d(Q)}
\]

\[
\leq \mathcal{L}(Q)\frac{d-1}{d} \|f - f_Q\|_{L^1(Q)}
\]

\[
\leq \mathcal{L}(Q)\frac{d-1}{d} \|f - f_Q\|_{L^\infty(Q)}
\]

\[
\leq \mathcal{L}(Q)\frac{d-1}{d} \text{var}_Q f
\]

\[
\leq \mathcal{L}(Q)\frac{d-1}{d} \text{var}_Q f < \infty.
\]

\( \square \)

**Proof of Theorem 1.1.** Let \( f \in L^1_{\text{loc}}(\Omega) \) with \( \text{var}_\Omega f < \infty \). We have \( |M_\Omega f| \leq M_\Omega |f| \) and \( \text{var}_Q f < \infty \). Hence it suffices to consider the case that \( f \geq 0 \). Let \( Q \) be a dyadic cube with \( Q \subset \Omega \). Then by Lemma 4.3

\[
c_Q = \sup_{Q \subset P \subset \Omega} f_P < \infty
\]

and on \( Q \) we have \( M_\Omega f = \max\{M_Q f, c_Q\} \). Thus by the maximal function theorem

\[
\int_Q (M_\Omega f) \frac{d}{d-1} \leq \mathcal{L}(Q)\frac{d}{d-1} + \int_Q (M_Q f) \frac{d}{d-1}
\]

\[
\leq \mathcal{L}(Q)\frac{d}{d-1} + C_d \int_Q f \frac{d}{d-1}
\]

which is finite by Sobolev embedding. Since every set \( U \) which is compactly contained in \( \Omega \) can be covered by finitely many dyadic cubes which are compactly contained in \( \Omega \), this implies \( M_\Omega f \in L^\frac{d}{d-1} (\Omega) \subset L^1_{\text{loc}}(\Omega) \). Thus Lemma 2.1 allows us to invoke Proposition 4.2 and we get

\[
\text{var}_\Omega M_\Omega f = \int_{\mathbb{R}^d} \mathcal{H}^{d-1}(\{x \in \Omega : M_\Omega f > \lambda\}) \lesssim \text{var}_\Omega f.
\]

\( \square \)

Remark 4.4. For \( f \in L^1_{\text{loc}}(\Omega) \subset L^1_{\text{loc}}(\Omega) \) the above arguments also show \( \tilde{M}_\Omega f \in L^\frac{d}{d-1} (\Omega) \) and \( \text{var}_\Omega \tilde{M}_\Omega f \lesssim \text{var}_\Omega f \).

We need more careful arguments to prove \( \tilde{M}_\Omega f \in L^1_{\text{loc}}(\Omega) \) and finish the proof of Theorem 1.2.

### 4.2 Membership of \( L^1_{\text{loc}}(\Omega) \)

Here we prove that \( \tilde{M}_\Omega f \in L^1_{\text{loc}}(\Omega) \) if \( f \in L^1_{\text{loc}}(\Omega) \). Note that for \( f \in L^1_{\text{loc}}(\Omega) \), with minor tweaks these arguments can be used as an alternative proof of \( f \in L^1_{\text{loc}}(\Omega) \).
Lemma 4.5. Let $Q$ be a dyadic cube and $f \in L^1(Q)$ with $\text{var}_Q f < \infty$ and $f \geq 0$. Then

$$\int_Q M_Q f \lesssim \int_Q f + L(Q)^{\frac{1}{p}} \text{var}_Q f.$$ 

Proof. We use the boundedness of the maximal operator on $L^{\frac{d}{d-1}}$ and the Gagliardo-Nirenberg-Sobolev inequality [13, Theorem 5.10 (ii)] for cubes. Split

$$\int_Q M_Q f = \int_Q f + \int_Q M_Q (f - f_Q)$$

and estimate

$$\int_Q M_Q (f - f_Q) \leq \left( \int_Q M_Q (f - f_Q)^{\frac{d}{d-1}} \right)^{\frac{d-1}{d}} \lesssim L(Q)^{\frac{d-1}{d}} \text{var}_Q f.$$

Lemma 4.6. Let $\Omega$ be open and $f \in L^1_{\text{loc}}(\Omega)$ with $\text{var}_\Omega f < \infty$. Then $\widetilde{M}_\Omega f \in L^1_{\text{loc}}(\Omega)$.

Proof. We have $|\widetilde{M}_\Omega f| \leq \widetilde{M}_\Omega |f|$ and $\text{var}_\Omega |f| \leq \text{var}_\Omega f < \infty$. Hence it suffices to consider the case that $f \geq 0$. Let $U \subset \Omega$ be open and bounded and depending on the setting with $\overline{U} \subset \Omega$. We have to show that $\int_U \widetilde{M}_\Omega f < \infty$. For each $\lambda \in \mathbb{R}$ let $Q'_\lambda$ be the set of cubes $Q$ that intersect $U$ and have $f_Q > \lambda$. Assume that for each $\lambda \in \mathbb{R}$ $\bigcup Q'_\lambda$ is unbounded. Since $U$ is bounded this means for each $n$ $Q''_n$ contains a nested sequence of cubes whose union is a quadrant. From those we can take a nested diagonal sequence $(Q_n)_n$ whose union is a quadrant and with $f_{Q_n} \to \infty$. But this contradicts Lemma 4.3. Hence there is a $\lambda_0$ such that $\bigcup Q'_\lambda$ is bounded. For each $\lambda \in \mathbb{R}$ let $Q_\lambda$ be the set of maximal cubes in $Q'_\lambda$. Then for $\lambda \geq \lambda_0$ we have $\bigcup Q'_\lambda = \bigcup Q_\lambda$ and

$$\int_U \widetilde{M}_\Omega f = \int_0^\infty \mathcal{L}(\{x \in U : \widetilde{M}_\Omega f > \lambda\}) \mathrm{d}\lambda$$

$$\leq \int_0^{\lambda_0} \mathcal{L}(U) \mathrm{d}\lambda + \int_{\lambda_0}^\infty \sum_{Q \in Q_\lambda_0} \mathcal{L}(\{x \in Q : \widetilde{M}_\Omega f > \lambda\}) \mathrm{d}\lambda$$

$$\leq \lambda_0 \mathcal{L}(U) + \sum_{Q \in Q_\lambda_0} \int_{\lambda_0}^\infty \mathcal{L}(\{x \in Q : \widetilde{M}_\Omega f > \lambda\}) \mathrm{d}\lambda.$$

Since $\mathcal{L}(U) < \infty$ it suffices to bound the second term in the previous display. For $x \in Q$ with $\widetilde{M}_\Omega f(x) > \lambda_0$ we have $\widetilde{M}_\Omega f(x) = M_Q f(x)$. Thus by Lemma 4.3 we have

$$\sum_{Q \in Q_\lambda_0} \int_{\lambda_0}^{\mathcal{L}(\{x \in Q : \widetilde{M}_\Omega f > \lambda\})} \mathrm{d}\lambda \lesssim \sum_{Q \in Q_\lambda_0} \int_Q f + \sum_{Q \in Q_\lambda_0} \mathcal{L}(Q)^{\frac{1}{p}} \text{var}_Q f$$

$$\leq \int_{\bigcup Q_\lambda_0} f + \mathcal{L}(\bigcup Q_\lambda_0)^{\frac{1}{p}} \text{var}_{\bigcup Q_\lambda_0} f.$$

This is finite because $\mathcal{L}(\bigcup Q_\lambda_0) < \infty$, $f \in L^1_{\text{loc}}(\Omega)$ and $\text{var}_\Omega f < \infty$. □
Proof of Theorem 1.2. By Lemma 4.6 we have $\tilde{M}_\Omega f \in L^1_{loc}(\Omega)$. Thus Lemma 2.1 allows us to invoke Proposition 4.2 and we get

$$\text{var}_\Omega M_\Omega f = \int_\mathbb{R} \mathcal{H}^{d-1}(\partial_\star \{x \in \Omega : M_\Omega f > \lambda\}) \lesssim \text{var}_\Omega f.$$

\qed

5 Further approaches

Now maybe the most obvious strategy to prove

$$\text{var} Mf \leq C_d \text{var} f$$

for the uncentered Hardy-Littlewood maximal operator is to transfer the arguments of this paper from dyadic cubes to balls, using ideas from [27]. So here is a potential alternative proof strategy of [3]. The idea is to conclude (4) for general functions $f$ from (4) for characteristic functions and subadditivity.

Claim 5.1. Let $M$ be a maximal operator. Assume that there is a functional $V : \text{BV}(\mathbb{R}^d) \to \mathbb{R}$ with the following properties. For a function $g$ with bounded variation and a characteristic function $h$ supported on $\{x : g(x) = \|g\|_\infty\}$ $V$ is subadditive,

$$V(g + h) \leq V(g) + V(h)$$

and

$$V(h) \leq C_d \text{var} h.$$  

Furthermore for all for all $f \in \text{BV}$ we have

$$\text{var} Mf \leq V(f).$$

Then we can conclude also for all $f \in \text{BV}$ that

$$\text{var} Mf \leq C_d \text{var} f.$$

Proof sketch. Let $h_1 \geq \ldots \geq h_n$ be characteristic functions. Then inductively we have

$$\text{var} M(h_1 + \ldots + h_n) \leq V(h_1 + \ldots + h_n)$$

$$\leq V(h_1 + \ldots + h_{n-1}) + V(h_n)$$

$$\leq V(h_1) + \ldots + V(h_n)$$

$$\leq C_d \text{var} h_1 + \ldots + \text{var} h_n$$

$$= C_d \text{var}(h_1 + \ldots + h_n),$$

and by approximation we can extend the estimate from sums of characteristic functions to general $f \in \text{BV}$.  

\qed
Note that $V = C_d \var$ satisfies (5) and (6), but the whole statement becomes trivial because then (7) is already what we want to prove. Still, this shows that the existence of a $V$ as in Claim 5.1 is actually equivalent to (4). However even for the dyadic maximal operator the only $V$ we have found is $C_d \var$.

Another candidate for $V$ is $\var M$, because we already know (6) from [27] and (7) is trivial. In [27] we even prove (6) for the uncentered Hardy-Littlewood maximal operator. But (5) unfortunately fails for both the dyadic and the uncentered Hardy-Littlewood operator, see Example 5.2.

**Example 5.2.** Let $d = 1$ and $g = 1_{[0,3)} + 1_{[5,8)}$ and $h = 1_{[2,3)} + 1_{[5,6)}$. Then for $f = g, h, g + h$ we have

$$\var M f = M f(2.5) + [M f(2.5) - M f(4)] + [M f(5.5) - M f(4)] + M f(5.5).$$

Thus

$$\var M g = 1 + (1 - 3/4) + (1 - 3/4) + 1 = 2.5,$$

$$\var M h = 1 + (1 - 1/2) + (1 - 1/2) + 1 = 3,$$

$$\var M (g + h) = 2 + (2 - 1) + (2 - 1) + 2 = 6 > 3 + 2.5.$$

The same counterexample works for the uncentered Hardy-Littlewood maximal function. It also works for $d > 1$ by defining $\tilde{g} : \mathbb{R}^d \to \mathbb{R}$ by $\tilde{g}(x) = g(x_1)1_{[-N, N]^d}(x)$ with $N$ large enough and $\tilde{h} : \mathbb{R}^d \to \mathbb{R}$ similarly.

However since maximal operators are pointwise subadditive, one might hope to find a modification of $\var M$ that is subadditive. The most promising candidate is $V(f) = \max\{\var M f, C_d \var f\}$. By [27] it satisfies (6) and it clearly also satisfies (7). In order to prove (5), by the subadditivity of $\var$ it suffices to prove that there is a $C_d$ such that

$$\var M (g + h) \leq \var M g + C_d \var h$$  \hspace{1cm} (8)

for $g, h$ as in Claim 5.1. That means from (8) one could conclude $\var M f \leq C_d \var f$. But even for the dyadic maximal operator (8) is still an open question. Note that in Example 5.2 we have $\var h = 4$ so it is not a counterexample against (8). Maybe (8) is still close enough to $\var M h \leq C_d \var h$ for characteristic functions to make use of [27]. One might also come up with more sophisticated functionals in between $\var M$ and $\var$ that satisfy the premise of Claim 5.1.
