Abstract

Background: FOLFIRINOX is a standard treatment for metastatic pancreatic cancer patients. The effectiveness of neoadjuvant FOLFIRINOX in patients with borderline resectable pancreatic cancer (BRPC) remains debated.

Methods: We performed a systematic review and patient-level meta-analysis on neoadjuvant FOLFIRINOX in patients with BRPC. Studies with BRPC patients who received FOLFIRINOX as first-line neoadjuvant treatment were included. The primary endpoint was overall survival (OS), and secondary endpoints were progression-free survival, resection rate, R0 resection rate, and grade III–IV adverse events. Patient-level survival outcomes were obtained from authors of the included studies and analyzed using the Kaplan-Meier method.

Results: We included 24 studies (8 prospective, 16 retrospective), comprising 313 (38.1%) BRPC patients treated with FOLFIRINOX. Most studies (n = 20) presented intention-to-treat results. The median number of administered neoadjuvant FOLFIRINOX cycles ranged from 4 to 9. The resection rate was 67.8% (95% confidence interval [CI] = 60.1% to 74.6%), and the R0-resection rate was 83.9% (95% CI = 76.8% to 89.1%). The median OS varied from 11.0 to 34.2 months across studies. Patient-level survival data were obtained for 20 studies representing 283 BRPC patients. The patient-level median OS was 22.2 months (95% CI = 18.8 to 25.6 months), and patient-level median progression-free survival was 18.0 months (95% CI = 14.5 to 21.5 months). Pooled event rates for grade III–IV adverse events were highest for neutropenia (17.5 per 100 patients, 95% CI = 10.3% to 28.3%), diarrhea (11.1 per 100 patients, 95% CI = 8.6 to 14.3), and fatigue (10.8 per 100 patients, 95% CI = 8.1 to 14.2). No deaths were attributed to FOLFIRINOX.
Pancreatic cancer is expected to be the second-leading cause of cancer-related death by 2030 (1). Approximately 20% of patients have borderline resectable pancreatic cancer (BRPC) or upfront resectable pancreatic cancer at diagnosis (2). Even after curative-intent surgery, cure is exceedingly rare, as demonstrated by a 10-year overall survival (OS) of 4% (3). Upfront resection with adjuvant chemotherapy has long been the standard of care for patients with localized pancreatic cancer. However, due to postoperative complications, deteriorating performance status, and early progressive disease, only about 55% of patients receive adjuvant chemotherapy (4–6). With a neoadjuvant approach, almost all patients receive systemic chemotherapy. This approach aims to address occult metastatic disease, increase the rate of R0 resection, and avoid futile surgery in patients with rapidly progressive disease (7).

Several neoadjuvant treatment regimens with or without chemoradiotherapy (CRT) have been proposed for BRPC patients (8–10). A combination chemotherapy regimen of folinic acid (leucovorin), fluorouracil (5-FU), irinotecan, and oxaliplatin (FOLFIRINOX) seems to be the most effective regimen for patients with pancreatic cancer. In a randomized, controlled trial (RCT), patients with metastatic pancreatic cancer had a superior OS with FOLFIRINOX compared with gemcitabine (median 11.1 vs 6.8 months, P < .001) (11). No RCT has been published with FOLFIRINOX in the neoadjuvant setting for BRPC patients. All published phase I–II trials and cohort studies on neoadjuvant FOLFIRINOX for BRPC patients are small and therefore report a wide range of median OS (12–15).

The primary aim of this systematic review and patient-level meta-analysis was to determine OS after neoadjuvant FOLFIRINOX as first-line treatment for patients with BRPC. Secondary outcomes included progression-free survival (PFS), resection rate, R0 resection rate, and grade III–IV adverse events (AEs).

**Methods**

**Eligibility**

We searched for studies containing treatment-naïve patients with BRPC treated with FOLFIRINOX as neoadjuvant therapy, irrespective of further treatment after FOLFIRINOX. Case reports, reviews, letters to the editor, conference abstracts without full text, and studies only reporting on specific groups of patients (eg, only patients in a specific age group) were excluded.

**Search Strategy**

This systematic review was performed in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analysis standard guidelines (16). To identify relevant studies, a comprehensive librarian-led search of Embase, MEDLINE (via OvidSP), Web of Science, Scopus, Cochrane Central, and Google Scholar was performed on September 1, 2017. Search terms included “FOLFIRINOX,” “folinic acid,” “fluorouracil,” “irinotecan,” “oxaliplatin,” “pancreas cancer,” “drug combination,” and relevant variants thereof. Only articles written in English were assessed. No restrictions on publication date were applied.

Literature without formal publication was not assessed. A full description of the search is summarized in the Supplementary Methods (available online).

**Selection Procedure and Data Collection**

After removal of duplicates, Q. P. Janssen and S. Buettner independently reviewed the abstracts for eligibility. The full-text article of any study that met the inclusion criteria was retrieved for further assessment. Full-text studies were excluded if only a regimen other than FOLFIRINOX was used, if the study did not include at least one BRPC patient, if the study was not an original report, or if the same patient cohort was presented in another study. Disagreements were resolved through discussion and consensus. Q. P. Janssen and S. Buettner extracted the data from selected studies with use of standardized data collection forms. The primary outcome was OS. Secondary outcomes were PFS, resection rates, R0 resection rates, and Common Terminology Criteria for Adverse Events grade III–IV (17). Other collected data included study characteristics (first author, year of publication, study design, inclusion period, duration of follow-up), study population specifications (total sample size, number of patients treated with FOLFIRINOX in total and per disease stage), and details on the intervention (FOLFIRINOX regimen, number of administered cycles, other treatments).

For the patient-level meta-analysis, we contacted the authors of all studies to obtain (updated) patient-level data on OS and PFS. Data were collected for BRPC patients only. The authors of four studies (14,18–20) provided patient-level data for additional BRPC patients not included in the reviewed articles. Data other than OS and PFS were not collected at the patient level but reported as aggregate outcomes from the published studies.

**Methodological Assessment**

All studies were assessed for risk of bias using an appraisal system developed by the Critical Appraisal Skill Program (21). This critical appraisal tool is designed to systematically assess the methodology of individual studies. Publication bias was assessed with a funnel plot (22).

**Statistical Analysis**

Patient-level survival outcomes were analyzed with the Kaplan-Meier method using the rms and survival packages for R 3.5.0 (https://cran.r-project.org/). The Kaplan-Meier method was used to account for censoring of patients alive or without recurrence at last follow-up. The primary survival outcome was OS, and the secondary outcome was PFS. Median, 1-year, 3-year, and 5-year survival were analyzed and reported for OS, and median, 1-year, 2-year, and 3-year for PFS. Patient-level survival outcomes were calculated from treatment initiation. One study only reported the date of surgery; therefore, 11 weeks were added to the date of surgery to account for a median of four cycles of FOLFIRINOX (8 weeks) with an additional 3-week interval to surgery (18). We performed post-hoc sensitivity analyses on patient-level survival data after exclusion of studies including
Results

Included Studies

We identified 2659 potentially relevant studies. Based on the abstracts, 54 studies were selected for full-text assessment, of which 24 studies (representing 1802 patients) fulfilled all inclusion criteria (Figure 1). Ten studies were excluded because only regimens other than FOLFIRINOX were used, 15 studies because no BRPC patients were included, 2 studies because the article was written in a language other than English, 1 study was a protocol, and 2 studies overlapped with other included studies (Supplementary Methods, available online).

Table 1 shows the study characteristics. Resectability status was defined by National Comprehensive Cancer Network criteria (42) in eight studies, Americas Hepato-Pancreato-Biliary Association/Society of Surgical Oncology/Society for Surgery of the Alimentary Tract criteria (43) in seven studies, the ALLIANCE criteria (44) in two studies, and other criteria (26,45–47) in four studies. Three studies did not report staging criteria. Most studies (n = 20) presented intention-to-treat results of all BRPC patients who started with neoadjuvant FOLFIRINOX, regardless of subsequent resection. Four studies included only patients who underwent a resection after neoadjuvant treatment (12,15,20,32). Eight studies included only patients with BRPC, 11 studies combined BRPC and locally advanced pancreatic cancer (LAPC) patients, and five studies combined all disease stages. For 89 patients in three studies, no distinction could be made between BRPC or LAPC; therefore, their results were only used for AEs and in patient-level analyses if BRPC was confirmed by the authors (32,35,36).

FOLFIRINOX was given to 822 (45.6%) patients, of whom 313 (38.1%) patients were staged as BRPC. Only nine patients (1.1%) from two studies had resectable pancreatic cancer (Table 1) (12,20). Patient-level data were obtained from 20 studies reflecting 283 BRPC patients, representing 90.4% of all published BRPC patients who received neoadjuvant FOLFIRINOX.

Methodological Assessment

We included eight prospective and 16 retrospective studies. Six studies were multicenter studies (Table 1). Results of the methodological assessment of all included studies are reported in Supplementary Table 1 (available online). The funnel plot showed no evidence of publication bias among the included studies (Supplementary Figure 1, available online).

Survival Analysis

Seven studies (12,13,20,25,28–30) representing 151 patients separately reported survival data for BRPC patients treated with neoadjuvant FOLFIRINOX. The median OS for BRPC patients varied across these seven studies from 11.0 to 34.2 months, and the median PFS varied from 5.7 to 21.3 months (Supplementary Table 2, available online).

Patient-level data were obtained for 283 BRPC patients who received neoadjuvant FOLFIRINOX, of whom 168 (59.4%) died during follow-up. The median follow-up of patients alive at last follow-up was 22.9 months. The overall patient-level median OS was 22.2 months (95% CI = 18.8 to 25.6 months) (Figure 2A). The pooled OS at 1 year was 76.0% (95% CI = 70.3% to 80.7%), at 3 years 36.2% (95% CI = 29.8% to 42.6%), and at 5 years 21.2% (95% CI = 14.6% to 28.6%). A total 115 of 283 patients (40.6%) were censored. After excluding 21 patients from two studies (20,32) that included only patients who underwent a resection, the patient-level median OS was similar (22.2 months, 95% CI = 18.8 to 25.7 months, P = .79). No statistically significant difference was observed when comparing OS of patients in prospective (21.7 months, 95% CI = 17.9 to 25.6 months) and retrospective studies (22.4 months, 95% CI = 17.7 to 27.2 months) (P = .36). For patients who were recurrence-free after 12 months, median OS was 43.2 months (95% CI = 37.0 to 49.4 months).

For studies in which patients received a median number of FOLFIRINOX cycles of six or fewer, the median OS was 21.4 months (95% CI = 16.7 to 26.0 months) compared with 21.7 months (95% CI = 15.0 to 28.4 months) for patients in studies with a median of less than six cycles (P = .46) (data not shown). No statistically significant association was found between the reported median number of FOLFIRINOX cycles administered and the patient-level median OS (Supplementary Figure 2, available online; P = .05). The median OS without upfront dose modification of FOLFIRINOX was 25.0 months (95% CI = 18.7 to 31.2 months) compared with 21.7 months (95% CI = 17.1 to 26.4 months) in studies with any dose modification (P = .18). The median OS in studies with G-CSF prophylaxis was 20.8 months (95% CI = 17.2 to 24.4 months) compared with a median OS of 18.5 months (95% CI = 13.2 to 23.8 months) in studies in which G-CSF was prescribed at the discretion of the treating physician (P = .42).
Patient-level PFS was available for 237 BRPC patients (20 studies), of whom 144 patients (59.8%) showed progression or died during follow-up, with a median PFS of 18.0 months (95% CI = 14.5 to 21.5 months; Figure 2B). A total 93 of 237 patients (39.2%) were censored. After excluding the two studies (20,32) reporting only patients who underwent a resection (n = 13), the median PFS was 18.0 months (95% CI = 14.6 to 21.4 months, P = .99). The PFS at 1 year was 68.5% (95% CI = 61.85% to 74.4%), at 2 years 39.4% (95% CI = 32.4% to 46.4%), and at 3 years 25.8% (95% CI = 19.4% to 32.6%). For prospective studies and retrospective studies, the median PFS was 18.4 months (95% CI = 12.1 to 24.8 months) and 17.7 months (95% CI = 14.4 to 21.0 months), respectively (P = .60).

Chemotherapy Regimens

Details of the chemotherapy regimen used are shown in Table 2. Only six studies reported the number of planned neoadjuvant FOLFIRINOX cycles for BRPC patients only, ranging from 4 to 8 cycles. Eleven studies reported the median number of FOLFIRINOX cycles administered to BRPC patients only, ranging from 4 to 9 cycles. Of these studies, five reported a median number of FOLFIRINOX cycles administered of six or more. Eight studies used a dose modification as compared with the FOLFIRINOX regimen described in the PRODIGE 4/ACCORD 11 trial (11); five studies did not include a fluorouracil bolus injection (13,27,28,34,39), four studies used a lower dose of irinotecan (27,34,35,41), three studies did not mention inclusion of leucovorin (27,28,34), and one study gave fluorouracil continuous infusion with doses halved (14). Seven studies did not specify the FOLFIRINOX regimen administered yet mentioned using modified FOLFIRINOX (50), FOLFOX or FOLFIRINOX (18), or FOLFIRINOX without mentioning upfront dose modifications (15,20,31,32,37). Use of G-CSF was reported as primary prophylaxis in seven studies (13,19,28,34,37,39,41) and was prescribed at the discretion of the treating physician in five studies (26,27,33,38,40).

Adverse Events

AEs during treatment with FOLFIRINOX were reported in 14 studies, of which nine studies reported only pooled outcomes across disease stages. In these 14 studies comprising 526 patients treated with FOLFIRINOX, 401 grade III or IV AEs were

*LAPC and BRPC patients pooled. AHPBA/SSO/SSAT = Americas Hepato-Pancreato-Biliary Association/Society of Surgical Oncology/Society for Surgery of the Alimentary Tract; BRPC = borderline resectable pancreatic cancer; DPCG = Dutch Pancreatic Cancer Group; LAPC = locally advanced pancreatic cancer; M+ = metastatic disease; MCW = Medical College of Wisconsin; MDACC = MD Anderson Cancer Center; NCCN = National Comprehensive Cancer Network; NR = not reported.
reported (Table 3). No deaths were attributed to FOLFIRINOX. Neutropenia, diarrhea, and fatigue were the most commonly reported grade III–IV AEs. Neutropenia had a pooled event rate of 17.5 per 100 patients (95% CI = 10.3 to 28.3, I² = 76.2%). The pooled event rates per 100 patients for other common AEs were 16.5 (95% CI = 8.4 to 29.9, I² = 0.0%) for leukopenia, 10.8 (95% CI = 8.1 to 14.2, I² = 0.0%) for fatigue, 11.1 (95% CI = 8.6 to 14.3, I² = 0.0%) for diarrhea, 10.4 (95% CI = 5.5 to 18.9, I² = 71.4%) for nausea or vomiting, 8.5 (95% CI = 5.2 to 13.7, I² = 0.0%) for thromboembolism, and 8.9 (95% CI = 6.2 to 12.5, I² = 4.3%) for thrombocytopenia. The pooled event rate for neutropenia was lower in six studies that administered G-CSF as primary prophylaxis compared with five studies with prescription of G-CSF at the discretion of the physician (eight per 100 patients vs 23 per 100 patients, P = .01; forest plot in Supplementary Figure 3, available online). The results were similar for febrile neutropenia (3 per 100 patients vs 10 per 100 patients, P = .02; forest plot in Supplementary Figure 4, available online).

Additional Treatment Modalities
Several studies reported the use of CRT (n = 8), stereotactic body radiation therapy (n = 4), or intra-operative radiation therapy (n = 4) besides FOLFIRINOX for at least one BRPC patient (Table 2). Neoadjuvant CRT was given as standard additional
treatment for BRPC patients in three studies (13,26,39) and reported as possible additional treatment in five other studies (12,20,25,29,34). No correlation was found between the percentage of (neo)adjuvant (chemo)radiation therapy and patient-level median OS (Supplementary Figure 5, available online, $P = .14$). Two studies were not included in this analysis because they included only patients who underwent a resection (12,20).

Resection and R0 Resection Rates

Fourteen studies reported resection rates for BRPC patients treated with neoadjuvant FOLFIRINOX (Table 2). The pooled resection rate was 67.8% (95% CI = 60.1% to 74.6%, $I^2 = 0.0%$). Resection margins were reported in 13 studies (Table 2). The pooled R0 resection rate in a random-effects model was 83.9% (95% CI = 76.8% to 89.1%, $I^2 = 0.0%$).

Discussion

This patient-level meta-analysis of 20 studies representing 283 patients who received neoadjuvant FOLFIRINOX for BRPC showed a median OS of 22.2 months (95% CI = 18.8 to 25.6 months). After neoadjuvant FOLFIRINOX, 67.8% (95% CI = 60.1% to 74.6%) of patients underwent a curative-intent resection with an R0 resection rate of 83.9% (95% CI = 76.8% to 89.1%). The rate of grade III or IV AEs was high, but no death was attributed to FOLFIRINOX.

FOLFIRINOX has been studied for patients with advanced pancreatic cancer since 2005 (48). For metastatic pancreatic

†Metastatic and borderline resectable pooled.
‡Metastatic, locally advanced, and borderline resectable pooled.
§Total events per 100 patients.
cancer, palliative FOLFIRINOX has been the standard of care for patients with a good performance status since an RCT found a median OS of 11 months vs 7 months with gemcitabine (11). In patients with LAPC, no RCT has been published for induction chemotherapy with FOLFIRINOX. The best available evidence of FOLFIRINOX for LAPC is a systematic review and patient-level meta-analysis of 315 patients (11 studies) that found a median OS of 24.2 months (95% CI = 21.7 to 26.8 months) (49). Figure 3 compares the patient-level OS of patients who received FOLFIRINOX in the setting of BRPC (present study) and LAPC (49). OS for both groups is clearly superior to OS for patients treated with FOLFIRINOX for metastatic pancreatic cancer in the RCT of Conroy et al. (11). It is remarkable that the median OS of 22.2 months for BRPC patients in this study is similar to the 24.2 months in the LAPC setting. The survival curves of LAPC and BRPC overlap for the initial 2 years, after which they diverge. OS after 3 years was 36.2% for BRPC vs 23.0% for LAPC patients. The difference in local extent of the disease between BRPC and LAPC appears to be irrelevant for about one-half of the patients who die within 2 years. The difference in OS after 2 years probably reflects both less advanced disease and a higher resection rate for BRPC (68% vs 27% in the LAPC setting) (49).

The use of radiation therapy after neoadjuvant FOLFIRINOX varied across studies. At the study level, no association was found between the percentage of patients who received neoadjuvant (chemo)radiation and median OS (Supplementary Figure 3, available online). Versteijne et al. performed a meta-analysis of intention-to-treat outcomes of any neoadjuvant approach vs upfront resection for (borderline) resectable pancreatic cancer [(B)RPC]. In a subgroup analysis comparing neoadjuvant approaches with and without radiation therapy, they also found no difference in OS (50). The interim analysis of the Dutch PREOPANC-1 trial, as presented at the ASCO annual meeting in 2018, showed a twofold increase in R0 resection rate, with 31% after upfront resection vs 65% after neoadjuvant CRT (P < .001) (51). Although the impact of RT on local control is convincing, it remains uncertain whether this translates into superior OS.

Many studies have found favorable OS for patients who undergo a resection of BRPC after neoadjuvant chemo(radio)therapy (52). However, some studies overestimated OS with neoadjuvant treatment, because OS was only reported for patients who underwent a curative-intent resection after neoadjuvant treatment, whereas patients who had progressive disease before resection were excluded. A recent meta-analysis resolved this selection bias by including only studies that adhered to the intention-to-treat principle: all patients who started neoadjuvant treatment were included in the analyses, regardless of whether they underwent a resection (50). Only 3% of these patients received neoadjuvant FOLFIRINOX. The authors found a superior median OS for any neoadjuvant approach (18.8 months) compared with upfront surgery (14.8 months) in (B)RPC patients. In 2018, the first two RCTs for neoadjuvant treatment of (B)RPC completed accrual (51,53). A
Korean trial was closed prematurely when interim analysis found a superior median OS of 21 months for neoadjuvant CRT vs 12 months with upfront surgery and adjuvant CRT ($P = 0.028$) (53). The previously mentioned interim analysis of the PREOPANC-1 trial found a median OS of 17.1 months with neoadjuvant gemcitabine-based CRT vs 13.7 months with upfront surgery and adjuvant gemcitabine ($P = 0.74$) (51). However, neither RCT investigated neoadjuvant FOLFIRINOX.

Because FOLFIRINOX is a more effective regimen than gemcitabine alone in the metastatic setting, it is expected that it further improves OS for patients with (B)RPC in the neoadjuvant setting. Four RCTs evaluating neoadjuvant FOLFIRINOX are currently accruing patients: the phase II ALLIANCE A021501 trial (NCT02839343) initially compared neoadjuvant mFOLFIRINOX with or without hypofractionated radiation therapy for BRPC, but recently closed the radiation therapy arm because it met the predefined futility boundary for R0 resection (54); the phase III NorPACT-1 trial (NCT02919787) for resectable pancreatic cancer comparing neoadjuvant FOLFIRINOX with upfront surgery, both followed by adjuvant gemcitabine and capecitabine (55); the phase II PANACHE2-PRODIGE48 trial (NCT02959879) for resectable pancreatic cancer comparing neoadjuvant FOLFIRINOX with neoadjuvant FOLFOX chemotherapy and upfront surgery, all followed by adjuvant chemotherapy (56); and the phase III PREOPANC-2 trial (NTR7292) comparing neoadjuvant FOLFIRINOX with neoadjuvant gemcitabine-based CRT for (B)RPC (57). Final results of these trials are not anticipated within the next 5 years. Meanwhile, experienced centers continue to publish impressive results in retrospective studies of neoadjuvant FOLFIRINOX for BRPC and LAPC. Most recently, Michelakos et al. published the updated series of Massachusetts General Hospital. For the combined group of BRPC and LAPC patients who underwent a resection after neoadjuvant FOLFIRINOX, they found a median OS of 37.7 months from diagnosis (58).

Median OS estimates after neoadjuvant treatment for BRPC may appear inferior to outcomes with adjuvant chemotherapy. For example, the ESPAC-4 trial reported a median OS of 28.0 months in the adjuvant gemcitabine-capacitabine arm (59). Moreover, the recent PRODIGE 24/CCTG PA.6 trial reported a median OS of 54.4 months in the adjuvant FOLFIRINOX arm (60). However, the patient populations of a neoadjuvant trial and an adjuvant trial are highly different and cannot be compared directly. To be eligible for an adjuvant trial, a patient has to overcome several hurdles. A small percentage of patients will never make it to the operating room, often because of a combination of drainage-related complications (eg, cholangitis or pancreatitis) and frailty. Moreover, about 20% of radiographically BRPC patients will never undergo resection because of occult metastatic disease at staging laparoscopy or unexpected LAPC during surgical exploration (61,62). Finally, most adjuvant trials require a complete macroscopic resection, a CA 19-9 level below 180 U/mL, and full recovery from surgery within 12 weeks after resection. In large nationwide studies, only about 55% of patients received adjuvant chemotherapy (4–6). Neoadjuvant trials include all those patients who drop out during treatment; only about one-third of these patients would be eligible for adjuvant trials after undergoing a resection and remaining fit for adjuvant chemotherapy. Excluding the worst two-thirds of patients will obviously have a major impact on the median OS.

After neoadjuvant FOLFIRINOX, resection rates ranged from 50% to 100% across studies. This substantial heterogeneity may be explained by the lack of consensus regarding resectability criteria and criteria to proceed with surgery after neoadjuvant treatment. Reaching consensus on resectability criteria is needed to improve comparison in future studies. In the pooled analysis of the present study, we found a resection rate of 68%. A similar resection rate of 66% was found in an intention-to-treat meta-analysis of (B)RPC patients treated with any neoadjuvant CRT regimen (50). The pooled R0 resection rate of 84% in the present study was higher compared with the intention-to-treat R0 resection rate of 67% with upfront surgery (50).

Some limitations of the present study should be considered. Although the present study represents the best available estimate of survival after neoadjuvant FOLFIRINOX for BRPC patients, it might be an overestimate because of the retrospective nature of most included studies. Similarly, secondary study endpoints such as AEs and PFS were prone to selection and information bias. Heterogeneity across studies also might have biased the results; studies used different resectability criteria, FOLFIRINOX regimens, and additional treatment (eg, CRT).

In conclusion, this patient-level meta-analysis of BRPC patients treated with neoadjuvant FOLFIRINOX showed a favorable median OS, resection rate, and R0 resection rate. These results need to be assessed in a randomized trial.
