We propose an adjoint $SU(5)$ GUT model with a $T_7$ family symmetry and an extra $Z_3 \otimes Z_4 \otimes Z_4' \otimes Z_{12}$ discrete group, that successfully describes the prevailing Standard Model fermion mass and mixing pattern. The observed hierarchy of the charged fermion masses and the quark mixing angles arises from the $Z_3 \otimes Z_4 \otimes Z_{12}$ symmetry breaking, which occurs near the GUT scale. The light active neutrino masses are generated by type-I and type-III seesaw mechanisms mediated by the fermionic $SU(5)$ singlet and the adjoint $24$-plet. The model predicts the effective Majorana neutrino mass parameter of neutrinoless double beta decay to be $m_{\beta\beta} = 4$ and $50$ meV for the normal and the inverted neutrino spectra, respectively. We construct several benchmark scenarios, which lead to $SU(5)$ gauge coupling unification and are compatible with the known phenomenological constraints originating from the lightness of neutrinos, proton decay, dark matter etc. These scenarios contain TEV-scale colored fields, which could give rise to a visible signal or be stringently constrained at the LHC.

I. INTRODUCTION

The LHC discovery of a $126$ GeV Higgs boson [1] has completed the era of the experimental quest for the missing elements of the Standard Model (SM). Now it is a well-established and extremely successful theory of the electroweak phenomena. However, the SM has several unaddressed issues, such as the smallness of neutrino masses, the observed pattern of fermion masses and mixings, and the existence of three fermion families [2], etc. The observed pattern of fermion masses spans over a range of 5 orders of magnitude in the quark sector and much wider considering neutrinos. Neutrino oscillation experiments demonstrated that at least two of the neutrinos are massive, with masses much lower, by several orders of magnitude, than the other SM fermions, and also that all of the three neutrino flavors mix with each other. The smallness of quark mixing contrasts with the sizable mixing of neutrinos: i.e., while in the quark sector all the mixing angles are small, in the neutrino sector two of them are large, and only one mixing angle is small. This suggests that the neutrino sector is described by a different kind of underlying physics than the quark sector. As is well known the tiny neutrino masses may point towards a high-energy scale of New Physics, where lepton number violation (LNV) takes place.

The physical observables in the neutrino sector, i.e., the neutrino mass-squared splittings and mixing parameters, are constrained from the global fits of the available data from neutrino oscillation experiments Daya Bay [3], T2K [4], MINOS [5], Double CHOOZ [6], and RENO [7], as shown in Tables I and II (based on Ref. [8]) for the normal (NH) and inverted (IH) hierarchies of the neutrino mass spectrum. As seen from these tables the neutrino oscillation experimental data show a clear evidence of a violation of the so-called tribimaximal symmetry described by the tribimaximal mixing matrix (TBM), predicting the neutrino mixing angles $(\sin^2 \theta_{12})_{TBM} = \frac{1}{3}$, $(\sin^2 \theta_{23})_{TBM} = \frac{1}{2}$, and $(\sin^2 \theta_{13})_{TBM} = 0$.

Addressing the flavor puzzle requires extensions of the SM, including larger scalar and/or fermion sectors, as well as an extended gauge group with additional flavor symmetries, which allow one to explain the SM fermion mass and mixing pattern. Along this line, several models have been proposed in the literature (for a review see, e.g., Refs. [9–13]). The fermion mass and mixing pattern can also be described by postulating particular mass matrix textures (see, e.g., Ref [40] for a comprehensive study of the

flavor symmetry of Ref. [29], and the nonsupersymmetric

GUT models. Some examples are the supersymmetric adjoint

$SU(5)$ GUT model with

$Z_2 \otimes Z_3 \otimes Z_4 \otimes Z_1^2 \otimes Z_{12}$

discrete group (see Ref [41] for a comprehensive study of the $T_7$ flavor group) extends the symmetry of the model, and several scalar fields are included to generate viable and predictive textures for the fermion sector. The particular role of each additional scalar field and the corresponding particle assignments under the symmetry group of the model are explained in detail in Sec. [41]. The fermionic sector of our model, in addition to the SM fermions, contains one heavy Majorana neutrino $N_R$, singlet under the SM group, and an adjoint $24$ fermionic irreducible representation (irrep) of $SU(5)$ so that the light neutrino masses are generated via type-I and type-III seesaw mechanisms. An adjoint $SU(5)$ GUT model, but without discrete symmetries, and more minimal particle content was previously considered in Ref. [41]. Although our model is less minimal than that of Ref. [41], it provides a successful description of the SM fermion mass and mixing pattern, not addressed in Ref.[41]. Also, our model is more predictive in the leptonic sector.

The model has 14 free effective parameters, which allow us to reproduce the experimental values of 18 observables with good accuracy: i.e., 9 charged fermion masses, 2 neutrino mass-squared splittings, 3 lepton mixing parameters, and 4 parameters of the Wolfenstein CKM quark mixing matrix parametrization. It is noteworthy that the alternative $SU(5)$ GUT model of Ref. [25], with a supersymmetric setup and flavor symmetries, also has 14 free effective parameters aimed at reproducing the above mentioned 18 observables. Discrete symmetries different from $T_7$ have also been employed in adjoint $SU(5)$ GUT models. Some examples are the supersymmetric adjoint $SU(5)$ GUT model with $A_4$ flavor symmetry of Ref. [29], and the nonsupersymmetric $SU(5)$ GUT model with $Z_4$ symmetry of Ref. [40].

The aforementioned SUSY adjoint $SU(5)$ GUT model with $A_4$ flavor symmetry employs two sets of $Z_2$ symmetries and two sets of $U(1)$ symmetries. One of these $U(1)$ symmetries is global and represents an $R$-parity symmetry, whereas the other $U(1)$ symmetry is assumed to be gauged. The two $Z_2$ symmetries shape the Yukawa matrices for quarks and charged leptons. That model includes Higgs multiplets in $1, 5, 5, 45$, dimensional representations of $SU(5)$. The 14 $SU(5)$ scalar singlets are grouped into three $A_4$ triplets and two $A_4$ trivial singlets. As in our model, neutrino masses arise from a combination of type-I and type-III seesaw mechanisms. Whereas in the model of Ref. [29], the CKM quark mixing matrix mainly arises from the down-type quark sector, in our model, the quark mixing is completely determined from the up-type quark sector. Furthermore, in this model the leptonic mixing angles are determined by two parameters, whereas in our model only one parameter determines the leptonic mixing
angles. Moreover, the quark masses and mixings are studied in detail in our model, whereas in the model of Ref. \[29\] a detailed study of quark masses and mixings is not included. Besides that, our model includes a detailed discussion of gauge coupling unification and seesaw mass scale limits, not performed in the model of Ref. \[29\]. With respect to the nonsupersymmetric adjoint $SU(5)$ GUT model with $Z_4$ discrete symmetry of Ref. \[30\], the discrete symmetry is introduced in that model in order to generate the nearest-neighbour-interaction textures for charged fermions. The scalar sector of that model includes an adjoint multiplet, a quintuplet and one 45-dimensional representation, and neutrino masses arise from type-I seesaw, type-III seesaw, and one-loop radiative seesaw mechanisms. Despite the fact that this model is more minimal than our

$T_7$ flavor adjoint $SU(5)$ GUT model, our model has a much more predictive lepton sector. Let us note that the lepton sector of the model of Ref. \[30\] has 12 effective free parameters, whereas the lepton sector of our model has a total of 6 effective free parameters. Unlike the models of Refs. \[29\] \[30\], our adjoint $SU(5)$ GUT model, which is non supersymmetric, employs a $Z_2 \otimes Z_3 \otimes Z_4 \otimes Z'_1 \otimes Z_{12}$ discrete symmetry.

After imposing gauge coupling unification equal to or better than that in the MSSM (another difference with respect to Refs. \[41\] \[42\], which impose exact gauge coupling unification), we find a wide set of simple field configurations, which pass proton decay constraints and give rise to the neutrino masses through a type-I and type-III seesaw realization. Considering the limit on the triplet scalar mass (denoted here as $\Xi_3$), which comes from the cold dark matter constraints pointed out in Ref. \[43\], we found lower limits on the seesaw scale for two simple scenarios with different sets of beyond-the-SM field configurations.

The paper is organized as follows. In Sec. \[II\] we outline the proposed model. In Sec. \[III\] we present our results on neutrino masses and mixing, followed by a numerical analysis. Our results for the quark sector, with the corresponding numerical analysis, are presented in Sec. \[IV\] Gauge coupling unification and seesaw scale mass limits are discussed in Sec. \[V\]. We conclude with discussions and a summary in Sec. \[VI\]. Some necessary facts about the $T_7$ group and details of our analysis are collected in appendices.

\section{II. THE MODEL}

The first grand unified theory (GUT) proposed in Ref. \[44\] is based on the $SU(5)$ gauge symmetry accommodating the SM fermions in $5 + 10$ and the scalars in $5 + 24$ irreps of $SU(5)$. As is well known this model suffers from several problems. In particular, it predicts wrong down-type quark and charged lepton mass relations and a short proton lifetime, and the unification of gauge couplings disagrees with the values of $\alpha_s$, $\sin \theta_W$ and $\alpha_{em}$ measured at the $M_Z$ scale. Moreover this minimal $SU(5)$ GUT model does not include a mechanism for generating nonvanishing neutrino masses in contradiction with experimental data on neutrino oscillations. The minimal $SU(5)$ GUT model can be improved by including, in particular, a scalar 45 irrep of $SU(5)$ \[42\] \[43\] \[45\] \[55\]. This next-to-minimal $SU(5)$ GUT model fails, however, in describing the observed pattern of fermion masses and mixings, due to the lack of explanation for the hierarchy among the large number of Yukawa couplings in the model. Below we consider a multi-Higgs extension of the next-to-minimal $SU(5)$ GUT model, which successfully describes the pattern of the SM fermion masses and mixing. The full symmetry $G$ of the model is broken in two subsequent steps as follows:

\begin{equation}
G = SU(5) \otimes T_7 \otimes Z_2 \otimes Z_3 \otimes Z_4 \otimes Z'_1 \otimes Z_{12} \\
\downarrow \Lambda_{GUT} \\
SU(3)_C \otimes SU(2)_L \otimes U(1)_Y \\
\downarrow \Lambda_{EW} \\
SU(3)_C \otimes U(1)_{em}
\end{equation}

Let us note that among the discrete symmetries we introduced the non-Abelian flavor symmetry group $T_7$, which is the smallest group with a complex triplet representation, allowing us to naturally accommodate the three families of fermions.

The fermion assignments under the group $G = SU(5) \otimes T_7 \otimes Z_2 \otimes Z_3 \otimes Z_4 \otimes Z'_1 \otimes Z_{12}$ are

\begin{equation}
\Psi^{(i)}_{ij} \sim (10, 1_0, 1, \omega, 1, 1, i), \quad \Psi^{(2)}_{ij} \sim (10, 1_1, 1, \omega^2, 1, 1, e^{2\pi i}), \quad \Psi^{(3)}_{ij} \sim (10, 1_2, 1, 1, 1, 1, 1), \quad i, j = 1, 2, 3, 4, 5
\end{equation}

\begin{equation}
\psi^i = \left(\psi^{i(1)}, \psi^{i(2)}, \psi^{i(3)}\right) \sim (\bar{5}, 3, 1, 1, 1, 1, 1), \quad N_R \sim (1, 1_0, -1, 1, 1, -1, -1), \quad \rho \sim (24, 1_0, -1, 1, 1, -i, 1),
\end{equation}

where $\omega = e^{2\pi i}$. 

More explicitly, the fermions are accommodated as
\[
\psi_{ij}^{(f)} = \frac{1}{\sqrt{2}} \begin{pmatrix}
0 & u_1^{(f)c} & -u_2^{(f)c} & -u_1^{(f)} & -d_1^{(f)} \\
-u_1^{(f)c} & 0 & u_2^{(f)c} & -u_1^{(f)} & -d_2^{(f)} \\
u_2^{(f)c} & -u_1^{(f)c} & 0 & -u_3^{(f)} & -d_3^{(f)} \\
u_1^{(f)c} & u_2^{(f)c} & u_3^{(f)} & 0 & -t^{(f)c} \\
-\zeta^{(f)} & d_1^{(f)} & d_2^{(f)} & d_3^{(f)} & t^{(f)c}
\end{pmatrix}_L,
\]
\[
\psi^{(f)} = \left(\begin{array}{ccccc}
d_1^{(f)c} & d_2^{(f)c} & d_3^{(f)c} & t^{(f)c} & -\nu_f
\end{array}\right)_L.
\]

Here the subscripts correspond to the different quark colors, while the superscript \(f\) refers to fermion families. One can see that the three families of left- and right-handed fermions, corresponding to the \(5\) irrep of \(SU(5)\), are unified into a \(T_7\) antitriplet \(\mathbf{3}\), while the three families of left- and right-handed fermions corresponding to the \(10\) irrep of \(SU(5)\) are assigned to the three \(T_7\) singlets \(\mathbf{1}, \mathbf{1}, \mathbf{1}\).

The scalar sector is composed of the following \(SU(5)\) representations: one \(24\), one \(45\), four \(5\)'s and ten \(1\)'s. Two sets of \(SU(5)\) singlets are unified into two \(T_7\) triplets. The remaining scalar fields, i.e., one \(45\), one \(24\), five \(5\)'s and the remaining four \(1\)'s, are accommodated by three \(T_7\) singlets. Thus the \(G\) assignments of the scalar fields are

\[
\sigma \sim 1, \mathbf{1}_0, 1, 1, 1, e^{-\frac{i\pi}{3}}, \quad \tau \sim 1, \mathbf{1}_0, 1, \omega, i, 1, e^{-\frac{i\pi}{3}}, \quad \xi = (\xi_1, \xi_2, \xi_3) \sim (1, \mathbf{3}, -1, 1, 1, 1),
\]

\[
\varphi \sim (1, \mathbf{1}_0, 1, \omega, -1, 1, 1), \quad \eta \sim (1, \mathbf{1}_0, 1, 1, -1, 1), \quad \chi = (\chi_1, \chi_2, \chi_3) \sim (1, \mathbf{3}, 1, 1, 1, 1, e^{\frac{i\pi}{3}}),
\]

\[
H_i^{(1)} \sim \mathbf{5}, \mathbf{1}_0, -1, 1, 1, e^{-\frac{i\pi}{3}}, \quad H_i^{(2)} \sim \mathbf{5}, \mathbf{1}_0, 1, 1, 1, \quad H_i^{(3)} \sim \mathbf{5}, \mathbf{1}_0, \omega^2, 1, 1, 1,
\]

\[
H_i^{(4)} \sim (5, 1_2, 1, 1, 1, 1), \quad \Xi_j \sim (24, \mathbf{1}_0, 1, 1, 1, 1, 1), \quad \Phi_{jk} \sim (45, \mathbf{1}_0, -1, 1, 1, 1, e^{-\frac{i\pi}{3}}).
\]

The VEVs of the scalars \(H_i^{(h)} (h = 1, 2, 3, 4)\) and \(\Xi_j\) are

\[
\left<H_i^{(h)}\right> = v_{H}^{(h)} \delta_{i5}, \quad h = 1, 2, 3, 4, \quad \left<\Xi_j\right> = \frac{2v_{\Xi}}{\sqrt{30}} \text{diag} \left(1, 1, 1, -\frac{3}{2}, -\frac{3}{2}\right), \quad i, j = 1, 2, 3, 4, 5.
\]

Note that the VEV pattern for the \(\Xi\) field given above is consistent with the minimization conditions of the model scalar potential and follows from the general group theory analysis of spontaneous symmetry breakdown [50].

The following comments about the possible VEV patterns for the \(T_7\) scalar triplets \(\chi\) and \(\xi\) are in order. Here we assume a hierarchy between the VEVs of the \(T_7\) scalar triplets \(\chi\) and \(\xi\), i.e., \(v_{\chi} << v_{\Xi}\), which implies that the mixing angle between the the \(T_7\) scalar triplets \(\chi\) and \(\xi\) is strongly suppressed since it is of the order of \(\frac{v_{\chi}}{v_{\Xi}}\), as follows from the method of recursive expansion of Refs. [57][59]. Consequently, the mixing between the \(T_7\) scalar triplets \(\chi\) and \(\xi\) can be neglected. The parts of the scalar potential for each of the two \(T_7\) scalar triplets at the renormalizable level are given by:

\[
V^{(1)}_{T_7} = -\mu_2^2 (\chi\chi^*)_{1_0} + \kappa_{\chi,1} (\chi\chi^*)_{\mathbf{3}} (\chi\chi^*)_{\mathbf{3}} + \kappa_{\chi,2} (\chi\chi^*)_{\mathbf{3}} (\chi\chi^*)_{\mathbf{3}} + \kappa_{\chi,3} (\chi\chi)_{\mathbf{3}} (\chi\chi^*)_{\mathbf{3}} + \kappa_{\chi,4} (\chi\chi^*)_{1_0} (\chi\chi^*)_{1_0} + \kappa_{\chi,5} (\chi\chi^*)_{1_1} (\chi\chi^*)_{1_2} + H.c.
\]

\[
V^{(2)}_{T_7} = -\mu_2^2 (\xi\xi^*)_{1_0} + \kappa_{\xi,1} (\xi\xi^*)_{\mathbf{3}} (\xi\xi^*)_{\mathbf{3}} + \kappa_{\xi,2} (\xi\xi^*)_{\mathbf{3}} (\xi\xi^*)_{\mathbf{3}} + \kappa_{\xi,3} (\xi\xi^*)_{\mathbf{3}} (\xi\xi^*)_{\mathbf{3}} + \kappa_{\xi,4} (\xi\xi^*)_{1_0} (\xi\xi^*)_{1_0} + \kappa_{\xi,5} (\xi\xi^*)_{1_1} (\xi\xi^*)_{1_2} + H.c.
\]

In the part of the scalar potential for each \(T_7\) scalar triplet there are six free parameters: one bilinear and five quartic
VEV direction: equations given by Eq. (9) and setting \[ \kappa \]

These results show that the VEV directions for the

In the case of

we find the relation between the parameters and the magnitude of the VEV:

From the expressions given in Eq. (9), and using the vacuum configuration for the scalar potential minimization equations satisfy as follows from the expressions given in Eq. (9). We have checked that the nonvanishing phases consistent with the

where \( m = 1, 2 \), \( S = \chi \), \( \xi \) and \( \langle S \rangle = (v_{S1}e^{i\theta_{S1}}, v_{S2}e^{i\theta_{S2}}, v_{S3}e^{i\theta_{S3}}) \). Then, from an analysis of the minimization equations given by Eq. (9) and setting \( \kappa_{\chi,2} = -\kappa_{\chi,3} \), we obtain for a large range of the parameter space the following VEV direction:

In the case of \( \xi \), this is a vacuum configuration preserving a \( Z_3 \) subgroup of \( T_7 \), which has been extensively studied by many authors (see, for example, Ref. [40]). The VEV pattern for \( \chi \) is similar to the one we previously studied in an \( SU(5) \) model and in a 6HDM with \( A_4 \) flavor symmetry [34, 69]. It is worth mentioning that there could be relative phases between the different components of \( \langle \xi \rangle \), consistent with the scalar potential minimization equations, as follows from the expressions given in Eq. (9). We have checked that the nonvanishing phases consistent with the scalar potential minimization equations satisfy \( \theta_{S_i} = -\theta_{S_j} \neq \theta_{S_k} \), with \( i \neq j \neq k \) \((i,j,k = 1,2,3)\). Moreover, we checked that the physical observables in the lepton sector, studied in Sec. III, do not depend on these phases. For generality we included nonzero phases in the \( \langle \chi \rangle \) sector, as indicated in Eq. (10).

From the expressions given in Eq. (9), and using the vacuum configuration for the \( T_7 \) scalar triplets given in Eq. (10), we find the relation between the parameters and the magnitude of the VEV:

These results show that the VEV directions for the \( T_7 \) triplets \( \chi \) and \( \xi \) in Eq. (10) are consistent with a global minimum of the scalar potential of our model.

Assuming that the charged fermion mass pattern and quark mixing hierarchy is caused by the \( Z_3 \), \( Z_4 \), and \( Z_{12} \) symmetries, and in order to relate the quark masses with the quark mixing parameters, we set the VEVs of the \( SU(5) \) scalar singlets as follows:

where \( \lambda = 0.225 \) is one of the parameters in the Wolfenstein parametrization and \( \Lambda \) is the high-energy scale cutoff of our model, to be clarified below. Assuming that the parameters of the scalar interaction terms involving these \( SU(5) \) scalar singlets are of the same order of magnitude, it is straightforward to show that the VEVs in Eq. (12) are consistent with the minimization conditions of the model scalar potential.

The fields \( \Phi^i_{jk} \), being the \( 45 \) irrep of \( SU(5) \), satisfy the following relations:

Consequently, the only allowed nonzero VEVs of \( \Phi^i_{jk} \) are

\[
\langle \Phi^{i}_{j3} \rangle = \frac{1}{3} \langle \Phi^{A}_{45} \rangle = v_{\theta}, \quad \langle \Phi^{i}_{j5} \rangle = v_{\phi} (\delta_{j}^i - 4\delta_{j}^i \delta_{j}^i), \quad i,j = 1,2,3,4,5, \quad p = 1,2,3,5. \tag{14}
\]
The lightest of the physical neutral scalar states of the scalar field $\Tr H^{(1)} \Psi_{ij} \frac{5^5}{\Lambda^5}$, and $\Psi$ irrep of $\SU_5$ spectrum and flavor mixing. Let as briefly sketch our justification of the model setup:

1. The scalar sector includes the following interaction terms, invariant under the group $\mathcal{G}$ and relevant for the further analysis:

$$\mathcal{L}_Y = \alpha_1 (\psi^i \xi^j)_{10} H^{(1)} \Psi_{ij} \frac{5^5}{\Lambda^5} + \alpha_2 (\psi^i \xi^j)_{10} H^{(1)} \Psi_{ij} \frac{5^5}{\Lambda^5} + \alpha_3 (\psi^i \xi^j)_{10} H^{(1)} \Psi_{ij} \frac{5^5}{\Lambda^5} + \beta_1 (\psi^i \xi^j)_{10} \Phi_{ij}^k \Psi_{jk} \frac{5^5}{\Lambda^5} + \beta_2 (\psi^i \xi^j)_{10} \Phi_{ij}^k \Psi_{jk} \frac{5^5}{\Lambda^5} + \beta_3 (\psi^i \xi^j)_{10} \Phi_{ij}^k \Psi_{jk} \frac{5^5}{\Lambda^5}$$

where the dimensionless couplings in Eq. (15) are $\mathcal{O}(1)$ parameters, and are assumed to be real, excepting $\gamma_{11}$, $\gamma_{12}$, $\gamma_{21}$, $\gamma_{31}$, and $\gamma_{13}$, which are assumed to be complex. The subscripts $10$, $1$, and $2$ denote projecting out the corresponding $T_7$ singlet in the product of the two triplets. Let us note that Eq. (15) is $SU(5)$ invariant, since the scalar fields $H^{(h)}_p$, $H^{(h)}_p$ ($h = 1, 2, 3, 4$), $\Phi_{ij}$, $\Phi_{jk}$ transform as $5$, $\overline{5}$, $45$, and $\overline{45}$ under $SU(5)$, respectively, and the fermionic fields $\psi^i$ and $\Psi_{ij}$ ($f = 1, 2, 3$) as $\overline{5}$ and $10$, under the $SU(5)$ group, respectively. Besides that, it is worth mentioning that the scalar field $H^{(h)}_p$ ($h = 1, 2, 3, 4$) transforms with the opposite $Z_4$ charges as compared to $H^{(h)}_p$. Furthermore, it is noteworthy that the term $Tr (\rho^2)$ is not present in Eq. (15), since this term is not invariant under the $Z_4$ symmetry. The lightest of the neutral scalar states of $H^{(1)}$, $H^{(2)}$, $H^{(3)}$, $H^{(4)}$ and $\Phi$, should be interpreted as the SM-like 126 GeV Higgs observed at the LHC.

Let us summarize and comment on the above presented model setup. In comparison with the next-to-minimal $SU(5)$ GUT model of Refs. [22, 43, 45, 55], besides for the introduction of additional discrete symmetries, we also extended the fermionic sector by introducing one heavy Majorana neutrino $N_R$, singlet under the SM group and a 24 fermionic irrep of $SU(5)$, namely $\rho^i$. We will show that since the $Z_4$ symmetry present in $\Phi$ is not preserved at low energies, the active neutrinos get tree-level masses via type-I and type-II seesaw mechanisms. In the next section, we will also show that in order to successfully accommodate the experimental data on neutrino mass-squared splittings, one needs both the SM singlet right-handed Majorana neutrino and the 24 fermionic irrep of $SU(5)$. Having only one of them would lead to two massless active neutrinos, in contradiction to the experimental data on neutrino oscillations. Note that our fermionic sector is less minimal than the one considered in Ref. [11] with only a 24 fermionic irrep of $SU(5)$. However, our model provides a successful description of the SM charged fermion masses and mixing pattern, not addressed in Ref. [11].

Despite the flavor-discrete groups in Eq. (1), the corresponding field assignment as well as the VEV pattern look rather sophisticated, although each introduced element plays its own role in the arrangement of the desired particle spectrum and flavor mixing. Let as briefly sketch our justification of the model setup:

1. The scalar sector includes the following $SU(5)$ representations: one 24, one 45, four 5’s and ten 1’s. The 45 and the four 5’s scalar irreps of $SU(5)$ acquire VEVs at the electroweak scale, thus inducing the second step of symmetry breaking. The remaining scalars acquire VEVs at the GUT scale and trigger the first step of symmetry breaking. As previously mentioned, having scalar fields in the 45 representation of $SU(5)$ is crucial to get the correct mass relations of down-type quarks and charged leptons.

2. The $T_7$ discrete group is crucial to generating textures for the lepton sector that successfully account for the experimentally observed deviation from the trimaximal mixing pattern that attracted a lot of attention in the literature as a framework for describing the lepton mixings; see for example Ref. [10]. To reproduce the nontrivial quark mixing consistent with experimental data, the up-type quark sector requires three 5’s, i.e., $H^{(1)}_i$, $H^{(3)}_i$, and $H^{(4)}_i$ irreps of $SU(5)$ assigned to different $T_7$ singlets. In the down-type quark sector, on the other hand, only one 5 irrep $H^{(1)}_i$, one 45 irrep $\Phi_{jk}$ assigned to $T_7$ trivial singlets and three 1’s, unified in the $T_7$ triplet $\xi$, are needed.
3. The $Z_2$ symmetry separates the scalars in the 5 and 45 irreps of $SU(5)$ participating in the Yukawa interactions for charged leptons and down-type quarks from those ones participating in the Yukawa interactions for up-type quarks. This implies that the $SU(5)$ scalar multiplets contributing to the masses of the down-type quarks and charged leptons are different from those that provide masses to the up-type quarks. Furthermore, the $Z_2$ symmetry separates the $T_7$ scalar triplet $\xi$ participating in the Yukawa interactions for charged leptons and down-type quarks, from that one ($\chi$) participating in the neutrino Yukawa interactions. In the scalar sector, the $Z_2$ symmetry distinguishes the $T_7$ scalar triplet $\xi$, the $SU(5)$ multiplets $H_i^{(1)}$ and $\Phi_{ik}^{(1)}$ charged under this symmetry, from the remaining scalar fields, neutral under this symmetry. Because of this, the 45 and one of the 5’s scalars participate in the Yukawa interactions for leptons and down-type quarks, whereas the remaining $SU(5)$ multiplets participate in the Yukawa interactions for up-type quarks. This results in a reduction of parameters in the quark sector, since due to the $Z_2$ symmetry the 45 scalar irrep of $SU(5)$ does not appear in the up-type quark Yukawa terms. Furthermore, all fermions are $Z_2$ even excepting the right-handed Majorana neutrino and the 24 fermionic irrep of $SU(5)$, which are $Z_2$ odd.

4. As with the $T_7$ symmetry, the $Z_4'$ symmetry is also necessary to get a predictive neutrino mass-matrix texture that only depends on three effective parameters and that gives rise to the experimentally observed deviation from the trimaximal mixing pattern. This symmetry also separates the 24 fermionic irrep $\rho$ and the charged under this symmetry from the remaining fermionic fields, neutral under this symmetry.

5. The $Z_3$ and $Z_4$ symmetries are crucial to getting the right pattern of charged lepton and down-type quark masses. The $Z_3$ symmetry distinguishes the three 10’s irreps of $SU(5)$, having different $Z_3$ charges. The $Z_4$ symmetry separates the $SU(5)$ scalar singlets $\varphi$ and $\tau$, charged under this symmetry, from the remaining scalar fields, neutral under this symmetry. All the fermionic parameters are assumed to transform trivially under the $Z_4$ symmetry. Without the $Z_3$ and $Z_4$ symmetries, the down quark and electron masses would be larger by about 2 orders of magnitude than their corresponding experimental values, unless one sets the corresponding Yukawa couplings unnaturally small. It is noteworthy that, unlike in the up-type quark sector, a $\lambda^8$ suppression ($\lambda = 0.225$ is one of the Wolfenstein parameters) in the 11 entry of the mass matrices for down-type quarks and charged leptons is required to naturally explain the smallness of the down quark and electron masses. The $Z_3$, $Z_4$, and $Z_{12}$ symmetries will be crucial to achieve that $\lambda^8$ suppression.

6. The $Z_{12}$ symmetry shapes the hierarchical structure of the quark mass matrices necessary to get a realistic pattern of quark masses and mixings. Besides that, the charged lepton mass hierarchy also arises from the $Z_{12}$ symmetry. Let us recall that due to the properties of the $Z_N$ groups, it follows that $Z_{12}$ is the lowest cyclic symmetry that allows building the dimension-ten up-type quark Yukawa term with a $\sigma^6/\Lambda^6$ insertion in a term of dimension four, crucial to getting the required $\lambda^6$ suppression in the 11 entry of the up-type quark mass matrix.

### III. LEPTON MASSES AND MIXING

The charged lepton mass matrix is derived from Eq. [15] by using the product rules for the $T_7$ group given in Appendix [A] and considering that the VEV pattern of the $SU(5)$ singlet $T_7$ scalar triplet $\xi$ satisfies Eq. [10] with the VEVs of their components set to be equal to $\lambda \Lambda$ ($\Lambda$ being the cutoff of our model), as indicated by Eq. [12]. Then, the mass matrix for charged leptons takes the form

$$M_l = \frac{v}{\sqrt{2}} V_{lL}^\dagger \begin{pmatrix} a_1^{(l)} \lambda^8 & 0 & 0 \\ 0 & a_2^{(l)} \lambda^5 & 0 \\ 0 & 0 & a_3^{(l)} \lambda^3 \end{pmatrix} = V_{lL}^\dagger \text{diag}(m_\ell, m_\mu, m_\tau) ,$$

(16)

with

$$a_1^{(l)} = \frac{1}{v} \left( \alpha_1 v_H^{(1)} - 6 \beta_1 v_\varphi \right), \quad a_2^{(l)} = \frac{1}{v} \left( \alpha_2 v_H^{(1)} - 6 \beta_2 v_\varphi \right), \quad a_3^{(l)} = \frac{1}{v} \left( \alpha_3 v_H^{(1)} - 6 \beta_3 v_\varphi \right),$$

(17)

$$V_{lL} = \frac{1}{\sqrt{3}} \begin{pmatrix} 1 & 1 & 1 \\ 1 & \omega & \omega^2 \\ 1 & \omega^2 & \omega \end{pmatrix}, \quad \omega = e^{\frac{2\pi i}{3}}.$$

(18)

Here $\lambda = 0.225$ is the Wolfenstein parameter. As was commented in the previous section, we assume that the dimensionless couplings $\alpha_i$ and $\beta_i$ ($i = 1, 2, 3$) in Eq. [15] are roughly of the same order of magnitude and the VEVs
\( v_H^{(1)} \) and \( v_\Phi \) are of the order of the electroweak scale \( v \simeq 246 \text{ GeV} \). Therefore, the hierarchy among the charged lepton masses arises from the breaking of the \( Z_3, Z_4 \) and \( Z_{12} \) symmetries. As seen, the lepton mass matrix Eq. (16) is fully determined in our model by three effective parameters \( \alpha_{1,2,3}^{(l)} \) shown in Eq. (17), which we fit to reproduce the experimentally measured values of lepton masses and mixings at the \( M_Z \) scale. A similar situation takes place in the sector of quarks, as will be shown in the next section.

From the neutrino Yukawa terms of Eq. (15) and taking into account that the VEVs of the \( SU(5) \) singlets \( \varphi, \sigma \) and \( \tau \) are set to be equal to \( \lambda \Lambda \) (where \( \Lambda \) is our model cutoff), as indicated by Eq. (12), we find that the fields contained in the 24 fermionic irrep of \( SU(5) \) acquire very large masses, which are given by

\[
\begin{align*}
    m_{\rho_0} &= y_2 v_\eta - \frac{y_3 v_\varphi v_\eta}{\sqrt{30} \Lambda}, \\
    m_{\rho_3} &= y_2 v_\eta - \frac{3y_3 v_\varphi v_\eta}{\sqrt{30} \Lambda}, \\
    m_{\rho_8} &= y_2 v_\eta + \frac{2y_3 v_\varphi v_\eta}{\sqrt{30} \Lambda}, \\
    m_{\rho_{(3,2)}} &= m_{\rho_{(\tau,2)}} = y_2 v_\eta - \frac{y_3 v_\varphi v_\eta}{2 \sqrt{30} \Lambda}.
\end{align*}
\]  
(19)

Here \( m_{\rho_0}, m_{\rho_3} \) and \( m_{\rho_8} \) are the masses of the fermionic singlet \( \rho_0 \), triplet \( \rho_3 \) and octet \( \rho_8 \) contained in the 24 fermionic irrep of \( SU(5) \), respectively. We denote by \( m_{\rho_{(3,2)}} \) and \( m_{\rho_{(\tau,2)}} \) the masses of the \((3,2)\) and \((\tau,2)\) fermionic fields corresponding to the \( SU(3) \) triplet and \( SU(3) \) antitriplet, \( SU(2) \) doublet parts of \( \rho \), respectively. Consequently, the light active neutrino masses arise from type-I and type-III seesaw mechanisms induced by the \( SU(5) \) singlet heavy Majorana neutrino \( N_R \), the fermionic singlet \( \rho_0 \) and the fermionic triplet \( \rho_3 \), respectively.

From the neutrino Yukawa terms of Eq. (15) and the VEV pattern of the \( SU(5) \) singlet \( T_\tau \) scalar triplet \( \chi \) given by Eq. (10), we find the neutrino mass matrix:

\[
\begin{align*}
    M_\nu &= \left( \begin{array}{c|cc|cc}
        O_{3 \times 3} & M_D & M_D^T \\
        \hline
        (M_\nu^D)^T & M_R
    \end{array} \right), \\
    M_D &= \left( \begin{array}{cc|ccc}
        0 & Y_1 e^{-i\phi} & Y_2 e^{-i\phi} & Y_2 e^{-i\phi} & Y_2 e^{-i\phi} \\
        X & 0 & 0 & 0 & 0 \\
        0 & Y_1 e^{i\phi} & Y_2 e^{i\phi} & Y_2 e^{i\phi} & Y_2 e^{i\phi}
    \end{array} \right), \\
    M_R &= \left( \begin{array}{cccc|cc}
        m_N & 0 & 0 & 0 & 0 & 0 \\
        0 & m_{\rho_0} & 0 & 0 & 0 & 0 \\
        0 & 0 & m_{\rho_3} & 0 & 0 & 0 \\
        0 & 0 & 0 & m_{\rho_3} & 0 & 0 \\
        0 & 0 & 0 & 0 & m_{\rho_3}
    \end{array} \right),
\end{align*}
\]  
(20)

where:

\[
X = (\lambda_{1\nu} + \lambda_{2\nu}) v_H^{(1)} \frac{v_\Phi^2}{\Lambda^2}, \quad Y_1 = \frac{\sqrt{15}}{2} \left( \frac{1}{5} \lambda_3 v_H^{(1)} + \lambda_4 v_\Phi \right) \frac{v_\Phi}{\Lambda}, \quad Y_2 = \left( \lambda_3 v_H^{(1)} - 3\lambda_4 v_\Phi \right) \frac{v_\Phi}{\Lambda}.
\]  
(21)

Therefore, the light neutrino mass matrix takes the following form:

\[
M_L = M_D M_R^{-1} M_D^T = \left( \begin{array}{cc|cc}
    A e^{-i\phi} & 0 & A \\
    0 & B & 0 \\
    A & 0 & A e^{i\phi}
\end{array} \right),
\]  
(22)

where

\[
A = \frac{Y_1^2}{m_{\rho_0}} + \frac{3Y_2^2}{m_{\rho_3}}, \quad B = \frac{X^2}{m_N}.
\]  
(23)

The smallness of neutrino masses in our model is the consequence of their inverse scaling with respect to the large masses of the singlet \( \rho_0 \) and the triplet \( \rho_3 \) fermionic fields and proportionality to the squared neutrino Yukawa couplings.
The mass matrix $M_L$ in Eq. (22) for light active neutrinos is diagonalized by a unitary rotation matrix $V_\nu$. There are two solutions of this diagonalization problem:

$$V_\nu^\dagger M_L V_\nu = \begin{pmatrix} m_1 & 0 & 0 \\ 0 & m_2 & 0 \\ 0 & 0 & m_3 \end{pmatrix}, \quad \text{with} \quad V_\nu = \begin{pmatrix} \cos \theta & 0 & \sin \theta e^{-i\phi} \\ 0 & 1 & 0 \\ -\sin \theta e^{i\phi} & 0 & \cos \theta \end{pmatrix} P_\nu, \quad \theta = \pm \frac{\pi}{4}, \quad (24)$$

$$P_\nu = \text{diag}(e^{i\alpha_1/2}, e^{i\alpha_2/2}, e^{i\alpha_3/2}). \quad (25)$$

The solutions corresponding to $\theta = +\pi/4$ and $\theta = -\pi/4$ we identify with the normal (NH) and inverted (IH) neutrino mass hierarchies, respectively, so that

$$\text{NH} : \theta = +\frac{\pi}{4} : \quad m_{\nu_1} = 0, \quad m_{\nu_2} = B, \quad m_{\nu_3} = 2A, \quad \alpha_1 = \alpha_2 = 0, \quad \alpha_3 = \phi, \quad (26)$$

$$\text{IH} : \theta = -\frac{\pi}{4} : \quad m_{\nu_1} = 2A, \quad m_{\nu_2} = B, \quad m_{\nu_3} = 0, \quad \alpha_2 = \alpha_3 = 0, \quad \alpha_1 = -\phi. \quad (27)$$

Let us note the presence of nonvanishing Majorana phases $\phi$ and $-\phi$ for NH and IH cases, respectively. This simple relation requires the effective dimensionful parameters $A$ and $B$, given by Eq. (23), to be real, which is consistent with our previously mentioned assumption that the dimensionless couplings in Eq. (15) are $O(1)$ parameters assumed to be real, excepting $\gamma_{11}$, $\gamma_{12}$, $\gamma_{21}$, $\gamma_{31}$ and $\gamma_{13}$, assumed to be complex.

Now we find the Pontecorvo-Maki-Nakagawa-Sakata (PMNS) leptonic mixing matrix,

$$U = V_{tL}^\dagger V_\nu = \begin{pmatrix} \cos \theta & \frac{-e^{i\phi} \sin \theta}{\sqrt{3}} & \frac{1}{\sqrt{3}} \\ \cos \theta & \frac{e^{i\phi} \sin \theta}{\sqrt{3}} & \frac{1}{\sqrt{3}} \cos \theta + \frac{e^{-i\phi} \sin \theta}{\sqrt{3}} \\ \cos \theta & \frac{e^{-i\phi} \sin \theta}{\sqrt{3}} & \frac{1}{\sqrt{3}} \cos \theta - \frac{e^{i\phi} \sin \theta}{\sqrt{3}} \end{pmatrix} P_\nu, \quad (28)$$

with the pattern of the trimaximal (TM2) type [61]. It is noteworthy that in our model the PMNS matrix depends on a single parameter $\phi$, and the neutrino masses [26] and [27] depend on two parameters, $A$ and $B$. Comparing the matrix $U$ in Eq. (28) with the standard parameterization of the PMNS matrix in terms of the solar $\theta_{12}$, the atmospheric $\theta_{23}$ and the reactor $\theta_{13}$ angles, we find

$$\sin^2 \theta_{12} = \frac{|U_{e2}|^2}{1 - |U_{e3}|^2} = \frac{1}{2 - z \cdot \cos \phi},$$

$$\sin^2 \theta_{13} = |U_{e3}|^2 = \frac{1}{3}(1 + z \cdot \cos \phi),$$

$$\sin^2 \theta_{23} = \frac{|U_{\mu 3}|^2}{1 - |U_{e3}|^2} = \frac{2 - z \cdot (\cos \phi + \sqrt{3} \sin \phi)}{4 - 2z \cdot \cos \phi}, \quad (29)$$

with $z = 1$ and $z = -1$ for NH and IH, respectively. Note that in the limit $\phi = 0$ and $\phi = \pi$ for IH and NH, respectively, the mixing matrix in Eq. (28) reduces to the tribimaximal mixing pattern, which yields a vanishing reactor mixing angle $\theta_{13}$.

For the Jarlskog invariant and the CP-violating phase [2], we find

$$J = \text{Im} \left( U_{e1} U_{\mu 2} U_{e2}^* U_{\mu 1}^* \right) = -\frac{1}{6\sqrt{3}} \cos 2\theta = 0, \quad \sin \delta = \frac{8J}{\cos \theta_{13} \sin 2\theta_{12} \sin 2\theta_{23} \sin 2\theta_{13}} = 0 \quad (30)$$

since $\theta = \pm \frac{\pi}{4}$ according to Eq. (24).

Thus, our model predicts a vanishing leptonic Dirac CP-violating phase.

In what follows, we adjust the three free effective parameters $\phi$, $A$ and $B$ of the active neutrino sector of our model to reproduce the experimental values of three leptonic mixing parameters and two neutrino mass-squared splittings, reported in Tables [I] and [II] for the normal and inverted neutrino mass hierarchies, respectively. We fit the parameter $\phi$ to adjust the experimental values of the leptonic mixing parameters $\sin^2 \theta_{ij}$, whereas $A$ and $B$ are fixed so that the
measured mass-squared differences are reproduced for the normal (NH) and inverted (IH) neutrino mass hierarchies. From Eqs. (27), (26), and the definition $\Delta m^2_{ij} = m^2_i - m^2_j$, we find

\begin{align*}
\text{NH} : & \quad m_{\nu_1} = 0, \quad m_{\nu_2} = B = \sqrt{\Delta m^2_{21}} \approx 9 \text{meV}, \quad m_{\nu_3} = 2 |A| = \sqrt{\Delta m^2_{31}} \approx 50 \text{meV}; \\
\text{IH} : & \quad m_{\nu_2} = B = \sqrt{\Delta m^2_{21} + \Delta m^2_{13}} \approx 50 \text{meV}, \quad m_{\nu_1} = 2 |A| = \sqrt{\Delta m^2_{13}} \approx 49 \text{meV}, \quad m_{\nu_3} = 0,
\end{align*}

for the best-fit values of $\Delta m^2_{ij}$ taken from Tables I and II.

To fit the leptonic mixing parameters $\sin^2 \theta_{ij}$ to their experimental values, given in Tables I and II, we vary the $\phi$ parameter, finding the following best fit result:

\begin{align*}
\text{NH} : & \quad \phi = -0.88 \pi, \quad \sin^2 \theta_{12} \approx 0.34, \quad \sin^2 \theta_{23} \approx 0.61, \quad \sin^2 \theta_{13} \approx 0.0232; \\
\text{IH} : & \quad \phi = 0.12 \pi, \quad \sin^2 \theta_{12} \approx 0.34, \quad \sin^2 \theta_{23} \approx 0.61, \quad \sin^2 \theta_{13} \approx 0.0238.
\end{align*}

Thus, $\sin^2 \theta_{13}$ is in excellent agreement with the experimental data, for both normal and inverted neutrino mass hierarchies, whereas $\sin^2 \theta_{12}$ and $\sin^2 \theta_{23}$ exhibit a 2$\sigma$ deviation from their best-fit values.

Now we are ready to make a prediction for the neutrinoless double beta ($0\nu\beta\beta$) decay amplitude, which is proportional to the effective Majorana neutrino mass parameter,

$$m_{\beta\beta} = \left| \sum_k U^2_{ck} m_{\nu_k} \right|,$$

where $U^2_{ck}$ and $m_{\nu_k}$ are the PMNS mixing matrix elements and the Majorana neutrino masses, respectively. Using Eqs. (24)-(28) and (31)-(34), we get for both normal and inverted hierarchies

$$m_{\beta\beta} = \frac{1}{3} \left( B + 4A \cos^2 \frac{\phi}{2} \right) = \begin{cases} 
4 \text{ meV} & \text{for NH} \\
50 \text{ meV} & \text{for IH}
\end{cases}$$

These values are beyond the reach of the present and forthcoming $0\nu\beta\beta$ decay experiments. The presently best upper limit on the effective neutrino mass is $m_{\beta\beta} \leq 160 \text{ meV}$, which arises from the recently quoted EXO-200 experiment [62] $T^{\beta\beta}_{1/2} \left( ^{136}\text{Xe} \right) \geq 1.6 \times 10^{25} \text{ yr}$ at 90% C.L. This limit will be improved within a not too distant future. The GERDA “phase-II” experiment [63, 64] is expected to reach a limit on the effective neutrino mass by 2025. The next generation or next-to-next generation $0\nu\beta\beta$ experiments, such as KATRIN [65], is currently under construction. It has an estimated sensitivity $T^{\beta\beta}_{1/2} \left( ^{130}\text{Te} \right) \sim 10^{26} \text{ yr}$, which corresponds to $m_{\beta\beta} \leq 10 \text{ meV}$. A bolometric CUORE experiment, using $^{130}\text{Te}$ [65], is currently under construction. It has an estimated sensitivity $T^{\beta\beta}_{1/2} \left( ^{130}\text{Te} \right) \sim 10^{26} \text{ yr}$, which corresponds to $m_{\beta\beta} \leq 1 \text{ meV}$. There are also proposals for ton-scale next-to-next generation $0\nu\beta\beta$ experiments with $^{136}\text{Xe}$ [66, 67] and $^{76}\text{Ge}$ [63, 68], claiming sensitivities over $T^{\beta\beta}_{1/2} \sim 10^{27} \text{ yr}$, corresponding to $m_{\beta\beta} \sim 12 - 30 \text{ meV}$. For recent reviews, see for example Ref. [69]. Consequently, as it can be seen from Eq. (36), our model predicts $T^{\beta\beta}_{1/2}$ at the level of sensitivities of the next generation or next-to-next generation $0\nu\beta\beta$ experiments.

**IV. QUARK MASSES AND MIXING**

Using Eq. (15), together with the product rules for the $T_7$ group given in Appendix A and considering that the components of the $SU(5)$ singlet $T_7$ scalar triplet $\xi$ acquire the same VEV as shown by Eq. (10), which is set to be equal to $\lambda \Lambda$ as the VEV of the $Z_{12}$ charged scalar $\sigma$ as indicated by Eq. (12) (A being the cutoff of our model), we find the quark mass matrices:

$$M_U = \frac{v}{\sqrt{2}} \begin{pmatrix} a_{11}^{(U)} \lambda^6 & a_{12}^{(U)} \lambda^5 & a_{13}^{(U)} \lambda^3 \\ a_{12}^{(U)} \lambda^5 & a_{22}^{(U)} \lambda^4 & a_{23}^{(U)} \lambda^2 \\ a_{13}^{(U)} \lambda^3 & a_{23}^{(U)} \lambda^2 & a_{33}^{(U)} \lambda^0 \end{pmatrix}$$

$$M_D = \frac{v}{\sqrt{2}} \begin{pmatrix} a_{11}^{(D)} \lambda^8 & 0 & 0 \\ 0 & a_{22}^{(D)} \lambda^5 & 0 \\ 0 & 0 & a_{33}^{(D)} \lambda^3 \end{pmatrix} \begin{pmatrix} V_{UL}^\dagger \end{pmatrix}^T = \text{diag} \left( m_d, m_s, m_b \right) \begin{pmatrix} V_{UL}^\dagger \end{pmatrix}^T,$$
where $\lambda = 0.225$ and the $O(1)$ dimensionless couplings in Eqs. (38) and (39) are given by:

$$
\begin{align*}
    a_{12}^{(U)} &= 2\sqrt{2} (\gamma_{12} + \gamma_{21}) \frac{v_1}{v}, \\
    a_{23}^{(U)} &= 2\sqrt{2} (\gamma_{23} + \gamma_{32}) \frac{v_2}{v}, \\
    a_{11}^{(U)} &= 4\sqrt{2} \gamma_{11} \frac{v_1}{v}, \\
    a_{13}^{(U)} &= 2\sqrt{2} (\gamma_{13} + \gamma_{31}) \frac{v_3}{v}, \\
    a_{22}^{(U)} &= 4\sqrt{2} \gamma_{22} \frac{v_2}{v}, \\
    a_{23}^{(U)} &= 4\sqrt{2} \gamma_{33} \frac{v_3}{v}, \\
    a_1^{(D)} &= \frac{1}{v} (\alpha_1 v_1 + 2\beta_1 v_8), \\
    a_2^{(D)} &= \frac{1}{v} (\alpha_2 v_1 + 2\beta_2 v_8), \\
    a_3^{(D)} &= \frac{1}{v} (\alpha_3 v_1 + 2\beta_3 v_8).
\end{align*}
$$

From Eq. (38) it follows that the CKM quark mixing matrix does not receive contributions from the down-type quark sector, meaning that quark mixing arises solely from the up-type quark sector. Consequently, having a realistic up-type quark masses and quark mixing angles requires that the mass matrix for up-type quarks to be given by:

$$
M_U = V_{CKM} \text{diag} (m_u, m_c, m_t) V^T_{CKM}.
$$

Using the standard parametrization for the CKM quark mixing matrix, together with the relations $m_u = a\lambda^6 m_t$ and $m_c = b\lambda^4 m_t$, where $a$ and $b$ are $O(1)$ coefficients, we get the mass matrix for up-type quarks described in Eq. (37), with entries exhibiting different scalings in terms of powers of the Wolfenstein parameter $\lambda = 0.225$. Thus, from the requirement of realistic up quark masses and quark mixing angles with $O(1)$ dimensionless couplings in Eq. (37), we find a $\lambda^6$ suppression in the 11 entry of the up-quark mass matrix instead of a $\lambda^8$ one. We have numerically checked that a $\lambda^3$ suppression in the 11 entry of the up-quark mass matrix, with $O(1)$ dimensionless couplings, is consistent with realistic up-quark masses and quark mixing angles.

Assuming that the quark mass and mixing pattern is caused by the breaking of the $Z_3$, $Z_4$ and $Z_{12}$ symmetries, to simplify our analysis, we adopt a benchmark where the dimensionless charged fermion Yukawa couplings are approximately equal. Specifically, we set

$$
\begin{align*}
    \gamma_{11} &= \left(1 - \frac{\lambda^2}{2}\right)^{1/2} \gamma_1 e^{i\phi_1}, \\
    \gamma_{12} &= \gamma_{21} = -\gamma_1 \gamma_2 \gamma_3 e^{i\phi_2}, \\
    \gamma_{22} &= \gamma_1 \left(1 - \frac{\lambda^2}{2}\right)^{-1/2}, \\
    \gamma_{13} &= \gamma_{31} = \gamma_2 \left(1 - \frac{\lambda^2}{2}\right)^3 e^{i\phi_3}, \\
    \gamma_{23} &= \gamma_{32} = -\gamma_2, \\
    \alpha_i &= \beta_i, \quad i = 1, 2, 3,
\end{align*}
$$

with $\gamma_1$, $\gamma_2$, $\gamma_3$ and $\alpha_i$ ($i = 1, 2, 3$) real $O(1)$ parameters. Our benchmark of nearly equal charged fermion Yukawa couplings given in Eq. (41), which we have numerically checked is consistent with realistic up-quark masses and quark mixing angles, is also adopted in order to reduce the number of free effective parameters in the quark sector of our model. There is no tuning in the parameters of our model. Let us note that the exactly equal dimensionless quark Yukawa couplings do not allow generating the up and charm quark masses. In Appendix B we give another possible motivation for the approximate universality of dimensionless couplings, which can be studied beyond the present model, adding new symmetries.

Besides that, for simplicity we assume that the complex phase responsible for CP violation in the quark sector arises solely from the up-type quark sector, as indicated by Eq. (41). In addition, to simplify the analysis, we fix $\gamma_{33}^{(D)} = 1$, as suggested by naturalness arguments. Consequently, the up-type quark mass matrix reads

$$
M_U = \begin{pmatrix}
    a_1^{(U)} & -a_1^{(U)} & a_2^{(U)} \\
    -a_1^{(U)} & a_1^{(U)} & 0 \\
    a_2^{(U)} & 0 & a_1^{(U)}
\end{pmatrix} \left(1 - \frac{\lambda^2}{2}\right)^{1/2} \lambda^6 e^{i\phi_1} \left(1 - \frac{\lambda^2}{2}\right)^{-1/2} \lambda^4 e^{i\phi_2} \left(1 - \frac{\lambda^2}{2}\right)^3 \lambda^3 e^{i\phi_3} \frac{v}{\sqrt{2}},
$$

As seen from the above formulas, the quark sector of our model contains ten parameters, i.e, $\lambda$, $a_{33}^{(U)}$, $a_1^{(U)}$, $a_2^{(U)}$, $a_1^{(D)}$, $a_2^{(D)}$, $a_3^{(D)}$, and the phases $\phi_i$ ($i = 1, 2, 3$), to describe the quark mass and mixing pattern, which is characterized by ten physical observables, i.e., the six quark masses, the three mixing angles and the CP phase. Out of the ten model parameters two of them, $\lambda$ and $a_{33}^{(U)}$, are fixed, whereas the remaining eight are fitted to reproduce the six quark masses and four quark mixing parameters. In Table III we show the experimental values of the physical observables in the quark sector, together with our results obtained for the following best-fit values of the model parameters:

$$
\begin{align*}
    a_1^{(U)} &\simeq 1.96, \\
    a_2^{(U)} &\simeq 0.74, \\
    a_1^{(D)} &\simeq 2.54, \\
    a_2^{(D)} &\simeq 0.58, \\
    \phi_1 &\simeq 10.94^\circ, \\
    \phi_2 &\simeq 6.02^\circ, \\
    \phi_3 &\simeq 21.65^\circ.
\end{align*}
$$
We use the experimental values for the quark masses at the $M_Z$ scale, reported in Ref. [70] (which are similar to those in [71]), whereas the experimental values of the CKM matrix elements, the Jarlskog invariant $J$ and the CP-violating phase $\delta$ are taken from Ref. [2]. Let us note that the agreement of our model with the experimental data is as good as in the models of Refs. [72, 79], and better than in Refs. [31, 80, 87]. The following comparison of our model with these models could be in order. Despite the similar quality of the data description our model is more predictive than the model of Ref. [72], since the latter, focused only on the quark sector, has a total of 12 free parameters, whereas the quark sector of our model is described by 8 free effective parameters that are adjusted to reproduce the total number of the effective free parameters of our model is 16, from which 2 are fixed and 14 are fitted to reproduce the experimental values of 18 observables in the quark and lepton sectors. On the other hand the $SU(5)$ model with $T' \otimes Z_{12} \otimes Z'_{12}$ symmetry of Ref. [31] has nine parameters in the Yukawa sector for the charged fermions and the neutrinos. However it does not account for CP violation in the quark sector, whereas our model does. Furthermore, the values of the physical observables we derived in our model for both quark and lepton sectors exhibit a significantly better agreement with their corresponding experimental values than those derived in Ref. [31] within the $SU(5)$ model with $T' \otimes Z_{12} \otimes Z'_{12}$ symmetry.

### Table III: Model and experimental values of the quark masses and CKM parameters.

| Observable | Model value | Experimental value |
|------------|-------------|--------------------|
| $m_u (MeV)$ | 0.86 | $1.45^{+0.56}_{-0.45}$ |
| $m_c (MeV)$ | 673 | 635 $\pm$ 86 |
| $m_t (GeV)$ | 174.2 | 172.1 $\pm$ 0.6 $\pm$ 0.9 |
| $m_d (MeV)$ | 2.9 | $2.93^{+0.5}_{-0.4}$ |
| $m_s (MeV)$ | 57.7 | $57.7^{+16.8}_{-15.7}$ |
| $m_b (GeV)$ | 2.82 | $2.82^{+0.09}_{-0.04}$ |

V. GAUGE COUPLING $SU(5)$ UNIFICATION

In the previous sections, we analyzed the possibility of describing the quark and lepton masses and flavor mixing within the framework of our model. This analysis was based on the symmetries of the model and particular field assignments to the symmetry group representations, which allowed us to single out several effective parameters completely determining the lepton and quark mass matrices. It is a notable property of the model that the SM fermion mass matrices depend on the “fundamental” parameters of the model Lagrangian only through this set of a few effective parameters. Now we turn to more subtle aspects of the model depending on the details of the non-SM components of the $SU(5)$ multiplets, as well as on the “fundamental” parameters, which may have crucial impact on its ultraviolet behavior.

As is well known, there are many extensions of the SM which lead to gauge coupling unification (GCU) and also successfully fulfill all the constraints coming from fermion masses, proton decay, and perturbativity. In particular, models based on supersymmetric and also non-supersymmetric (non-SUSY) $SU(5)$ unification have been widely studied in the literature [72, 88]. For non-SUSY $SU(5)$ scenarios, the unification of gauge couplings can be as good as or
better than in the MSSM, despite the fact that the number of extra fields beyond the SM is smaller. More restrictive conditions such as the possibility of implementation of an appropriate neutrino mass generation mechanism, and compatibility with the existing phenomenological, cosmological and astrophysical constraints, require some specific properties for this extra field content. As was already pointed out in Sec. II, the $SU(5)$ scalar representations with the minimal number of Higgs bosons needed to generate the fermion masses and mixings are one $24_{s}$, one $45_{s}$, four $5_{s}$’s, and twelve $1_{s}$’s. If an extra fermionic $24_{f}$ representation is also included, a simple configuration of the extra fields allowing the type-I and type-III seesaw mechanisms of neutrino mass generation can be constructed with masses below the GUT scale. As will be shown later the condition of the GCU and compatibility with the lower experimental limit on the proton decay half-life predicts the masses for the extra scalar fields within the LHC reach. This opens up the possibility for experimental tests of the considered models. On the other hand, the dark matter constraints on the scalar sector will lead us to the conclusion that the masses for the type-I and type-III fermionic seesaw mediators, $m_{\nu_{R}}, m_{\rho_{0}}$ and $m_{\rho_{3}}$, should be at high energies far beyond the TeV ballpark.

It is noteworthy to mention that our configurations rely on fine-tuning which separate light from heavy degrees of freedom. However, this issue is an unavoidable problem of grand unified theories. Evidence of this is the standard $SU(5)$, which suffers from what is known as the doublet-triplet splitting problem i.e., the fact that the SM Higgs doublet has a mass of $\sim 125$ GeV while the colored triplet in the 5 irrep must have a mass of the order of the GUT scale in order to prevent proton decay. Although several solutions to this problem have been suggested in the literature (for a short review, see Ref. [89]), we do not consider here any particular one. Instead, we view this as a fine-tuning problem and, in fact, to make the exotic particles in our model light will require, in general, additional fine-tunings. We assured ourselves that the large number of free and uncorrelated parameters in the scalar potential will allow us to reproduce the required mass differences. There are non-SUSY $SU(5)$ models which also heavily rely on fine-tuning among states, and which do not consider formal solutions to this problem, as seen in Refs. [30,42]. We are aware of this fine-tuning problem, whose formal solution goes beyond the scope of this work and is deferred for a future publication.

1. Setup

The scalar sector of our model is composed, as described in the previous sections, by the $5_{s}$, $24_{s}$, and $45_{s}$ irreps of $SU(5)$ with the following $SU(3)_{C} \times SU(2)_{L} \times U(1)_{Y}$ decompositions:

$$5_{s} = (1,2)_{1/2} \oplus (3,1)_{-1/3},$$
$$= H_{1} \oplus H_{2},$$
$$24_{s} = (1,1)_{0} \oplus (1,3)_{0} \oplus (8,1)_{0} \oplus (3,2)_{-5/6} \oplus (\bar{3},2)_{5/6},$$
$$= \Xi_{1} \oplus \Xi_{3} \oplus \Xi_{8} \oplus \Xi_{(3,2)} \oplus \Xi_{(\bar{3},2)},$$
$$45_{s} = (1,2)_{1/2} \oplus (3,1)_{-1/3} \oplus (3,3)_{-1/3} \oplus (3,1)_{4/3} \oplus (\bar{3},2)_{7/6} \oplus (6,1)_{-1/3} \oplus (8,2)_{1/2},$$
$$= \Phi_{1} \oplus \Phi_{2} \oplus \Phi_{3} \oplus \Phi_{4} \oplus \Phi_{5} \oplus \Phi_{6} \oplus \Phi_{7}. \tag{44}$$

The SM Higgs doublet is embedded in the $5_{s}$. The adjoint $24_{s}$ representation triggers the breaking of $SU(5)$ to the SM at the GUT scale. As we previously commented, this particle content should be further extended in order to account for the nonzero neutrino masses. We introduced a fermionic $24_{f}$ irrep of the $SU(5)$. It has the SM decomposition

$$24_{f} = (1,1)_{0} \oplus (1,3)_{0} \oplus (8,1)_{0} \oplus (3,2)_{-5/6} \oplus (\bar{3},2)_{5/6},$$
$$= \rho_{0} \oplus \rho_{3} \oplus \rho_{8} \oplus \rho_{(3,2)} \oplus \rho_{(\bar{3},2)}. \tag{45}$$

In this case the $SU(5)$ singlet $N_{R}$ Majorana neutrino with the heavy SM singlet $\rho_{0}$ mediate type-I seesaw mechanism while the $SU(2)_{L}$ triplet $\rho_{3}$ gives rise to the type-III seesaw mechanism. Combining these three extra fermions, $N_{R}$, $\rho_{0}$, and $\rho_{3}$, with some of the scalar fields from the $5_{s}$, $24_{s}$, and $45_{s}$ irreps, we construct the simplest benchmark configurations that unify the gauge couplings within the $SU(5)$ and satisfy some general requirements in order to guarantee their phenomenological viability. These requirements are

(i) **Perturbative $SU(5)$ unification**: This means that gauge couplings unify as well as or even better than in the MSSM, and the value of $\alpha_{G}$ is in the perturbative regime. Note that we are not necessarily imposing the exact unification of the gauge couplings at the GUT scale ($m_{G}$). Rather, we allow for a difference of the gauge couplings at $m_{G}$ falling into the area of the MSSM "nonunification triangle" [90,91].

(ii) **Proton decay**: There are some specific fields contributing to proton decay. The dimension-six proton decay
operators are mediated by the superheavy gauge bosons, usually named leptoquarks, in the $24$ irrep: $\rho(3,2) \oplus \rho(\overline{3},2) = (3, 2, -5/6) \oplus (\overline{3}, 2, 5/6)$, which must be heavier than $3 \times 10^{15}$ GeV to satisfy the experimental lower bound on the proton decay lifetime. Here, we assume that these fields live at the GUT scale. In addition, we deal with field configurations which, in almost all the parameter space, fulfill the current constraint from $\tau \rightarrow e^+e^-$, $\Gamma \geq 10^{34}$ years \cite{92, 93}. This, through the relation for the proton decay half-life, $\Gamma = \alpha_m^2 m_m^5 / m_r^5$, leads to a GUT scale of $m_G \gtrsim 3 \times 10^{15}$ GeV.

(iii) Fermion masses: In particular, neutrino mass generation through the type-I and type-III seesaw mechanisms \cite{11, 94}. The configurations should then contain at least one copy of the fermionic fields $N_R$, $\rho_0$, and $\rho_3$, as described before.

(iv) Nontrivial phenomenology: Among the models passed through the above three conditions, we select those models which may provide a distinguishing signal at the LHC.

In what follows, we analyze some of the "minimal" benchmark models, which lead to correct unification and also fulfill the above listed requirements, with as simple a field content as possible. As the preferable models, we consider those which are phenomenologically rich enough, in the sense that some of the fields (being colored) could give rise to certain resonances at the LHC. The analyzed models will lead to an available parameter space for the different masses of the scalars and the type-I, type-III seesaw fermionic mediators.

2. The Models

For simplicity, and following the notations of Ref. \cite{13}, we rewrite the masses of the fermionic $24_f$ given in Eq. \eqref{eq:19} as follows:

$$m_{\rho_3} = m - 3 e^{i\alpha} \Lambda',$$
$$m_{\rho_3} = m + 2 e^{i\alpha} \Lambda',$$
$$m_{\rho_{(3,2)}} = m_{\rho(\tau, 2)} = m - 1/2 e^{i\alpha} \Lambda',$$
$$m_{\rho_3} = m - e^{i\alpha} \Lambda'.$$

(46)

where $\alpha$ is the relative phase between $y_2$ and $y_3$. For the particular case where $c = 0$, the parameters $\Lambda'$ and $m$ are then defined as $m = y_2 v_2$ and $\Lambda' = y_3 v_3 = e^{i\alpha} \Lambda$ (where $y_3 = y_3 / \sqrt{30}$).

In order to deal with the simplest models, we look for configurations where the only contribution from the fermionic $24_f$ to the RGE flow comes from the fermionic type-I and type-III seesaw mediators. We assume the other $24_f$ components, $\rho_8$, $\rho_{(3,1)}$, and $\rho_{(\overline{3},2)}$, have no RGE effect, being as heavy as the GUT scale. It is worth reiterating that in the analyzed benchmark models the GCU is achieved having a few particles with masses below the GUT scale: the fermions $N_R$, $\rho_0$, $\rho_3$ plus some of the extra scalar fields from the $5_s$, $24_s$, and $45_s$ multiplets. This kind of spectra can be easily obtained by fine-tuning Eq. \eqref{eq:46}, imposing that the mass of the remaining fermionic fields in the $24_f$ lives at the GUT scale or above.

Searching for the models, we keep our analysis at the one-loop level. It could be easily extended to two loops. However, this sophistication makes no impact on our final results and conclusions.

The master equation for the running of the inverse gauge couplings at the one-loop level is

$$\alpha_i^{-1}(\mu) = \alpha_{i0}^{-1}(\mu_0) - \frac{b_i^{eff}(\mu)}{2\pi} \ln \left( \frac{\mu}{\mu_0} \right), \quad \text{with} \quad i = 1, 2, 3$$

(47)

The effective one-loop RGE coefficients, taking into account the thresholds from particles with masses $m_f$, are given by

$$b_i^{eff}(\mu) = \sum_f \theta(\mu - m_f) b_i^f.$$  

(48)

The contribution of each particle $b_i^f$ is calculated according to

$$b_i = -\frac{11}{3} T_i(R_G) + \frac{2}{3} T_i(R_F) + \frac{1}{3} T_i(R_B).$$

(49)

where $T(R_I)$ are the Dynkin indexes of the representations $R_I$ to which belong $I = G$, $F$, and $B$-the gauge bosons, fermions, and scalars, respectively. They are defined as $T(R) \delta_{mn} = \text{Tr}(T_m(R) T_n(R))$, with $T_m(R)$ being generators.
in the representation $R$. For the lowest-dimension representations of $SU(N)$ they are $T(\text{fundamental}) = 1/2$, $T(\text{Adj}) = N$. For the SM we have $(b_5^S, b_8^S, b_8^S) = (-7, -19/6, 41/10)$, which correspond to the contributions of the SM fermions and one copy of the $\tilde{SU}(2)_L$ Higgs doublet. The additional non-SM fields introduce extra contributions $\Delta b_i$ to these coefficients $b_i = b_i^S + \Delta b_i$. In Table IV, Appendix C the $\Delta b_i$ contributions of the fields in the $5_S$, $10_S$, $24_S$, $24_f$, and $45_S$ $SU(5)$ representations are shown. In order to correctly unify the gauge couplings and fulfill all the requirements (i)-(iv) in Sec. V 1, which we impose on the models, these $\Delta b_i$ coefficients should obey certain conditions. Some of the simplest configurations of the non-SM fields with the masses below the GUT scale, which obey these conditions, are listed in Table V, Appendix C. All the listed field configurations have a highly split mass spectrum with type-I and type-III seesaw mediators at $m_S \sim 10^{14}$ GeV and remaining scalars at $m_{NP} = 2$ TeV. Let us note that since among the scalars there are the color octets, we use 2 TeV as a limit recently established on the mass of color octets by the CMS and ATLAS collaborations [95] from the dijet pair signature searches. We have purposely chosen the latter scale to be low enough so that the colored scalars are within the LHC’s mass reach, while the large value for the seesaw scale $m_S$ is in agreement with the small neutrino masses. Let us consider two simplest models (1) and (2) from Table V.

**Model (1)** This is the simplest of all the benchmark models passing our conditions (i)-(iv) in Sec. V 1, including the unification of the gauge couplings and smallness of neutrino masses. However, if we fix the masses of the scalar fields $\Xi_{3_{0,8}}$ at $m_{NP} = 2$ TeV and the fermionic seesaw mediators $\rho_{0,3}$, $N_R$ at $m_S = 10^{14}$ GeV, as it is done for all the models in Table V we get the GUT scale $m_G = 2.7 \times 10^{15}$ GeV, which is in slight tension with the limit imposed by the proton stability $m_G \gtrsim 3 \times 10^{15}$ GeV. This flaw can easily be cured by allowing the masses of the fields to vary independently in the range $2 \text{ TeV} \leq m_{\Xi_3}, m_{\Xi_8} \leq m_S < m_G$. Now, as shown in Fig. 1, a significant part of the model parameter space corresponds to the GUT scale in the range allowed by the proton decay constraint. From the left panel of this figure we can see that in this part of the parameter space the masses $m_S$ of the seesaw mediators $\rho_{0,3}$, $N_R$ could be in the ballpark of $[10^{8.5}, 10^{15.5}]$ GeV. The right panel of Fig. 1 shows that in the part of the parameter space consistent with the proton decay constraints, the mass of the scalar octet $\Xi_8$ is relatively low, 2 TeV $< m_{\Xi_8} \lesssim 10^6$ GeV. Thus, there is a chance for $\Xi_8$ to be within the mass reach of the current run of the LHC. However, its production cross section suffers from several suppression factors. The process of single-$\Xi_8$ production is only possible in the gluon fusion $qg \to \Xi_8$ via a loop with two or three internal $\Xi_8$, which is suppressed by the large $m_{\Xi_8}$. On the other hand, as seen from Eq. 15, it cannot be produced in $q\bar{q} \to \Xi_8$. The tree-level pair production process $gg \to \Xi_8$ being not suppressed in the amplitude, has a high threshold of $2m_{\Xi_8}$. If produced, $\Xi_8$ decays in a unique channel $\Xi_8 \to gg$. However, the corresponding signal at the LHC could be challenging from the viewpoint of the identification of its origin. Below we consider another benchmark model with a more distinctive signature of the color octet from 45.

A viable dark matter (DM) candidate in non-SUSY models is an issue requiring special efforts. References 43, 90 recently proposed the neutral component $\Xi^0$ of the $\Xi_3 \sim (1, 3)_0 \subset 24_8$, as a scalar cold dark matter (CDM) candidate. The necessary condition for its stability is the vanishing of the trilinear coupling of $H^\dagger \Xi_3 H$ with the SM Higgs doublet, $H$. Also, its VEV must be zero, $\langle \Xi^0 \rangle = 0$. These conditions, as shown in Ref. 43, can be implemented by an ad hoc fine-tuning of the scalar potential parameters. Unfortunately, no proper custodial symmetry, protecting this fine-tuning, can be incorporated in the adjoint $SU(5)$ framework 43. Despite this complication, we study constraints on our model from the assumption that the $\Xi^0$ is a CDM candidate. It has been shown in Ref. 90 that the thermal relic abundance could be compatible with the observed DM abundance $\Omega_{DM} h^2 = 0.110 \pm 0.005$, if $m_{\Xi_3} \sim 2.5$ TeV. We use this fixed value as a condition allowing the presence of a viable CDM particle candidate $\Xi^0$ in the model. In Fig. 2 we show limitations on the model parameter space, taking into account this condition. As seen, the lowest bound on the seesaw mediator mass is $m_S \gtrsim 10^{13}$ GeV. This large value of the seesaw mass scale perfectly accounts for the smallness of the neutrino masses.

**Model (2):** This is the next simplest benchmark model from Table V. It contains a scalar color octet $\Phi_7 \sim (8, 2)_{1/2} \subset 45$. Its production and possible signals at the LHC have been studied in Ref. 97 (for the earlier studies of the color octet scalars at the LHC see, for instance, Ref. 98). The neutral and charged components $S^0_{R,1}, S^\pm$ of this multiplet, unlike the $\Xi_8$ in Model (1), can be singly produced at tree level in quark-antiquark annihilation $q\bar{q} \to S^0_{R,1}, q\bar{q} \to S^\pm$ and in the gluon fusion at one-loop level via $b$-quark loop, which is much less suppressed than the loop-induced production of a single $\Xi_8$. The tree-level pair production, dominated by the gluon fusion $gg \to S^0 S^0, S^+ S^-$, is approximately an order of magnitude smaller than the single-$S$ production at $m_S \sim 2$ TeV, according to Ref. 97. However, the single-$S$ production cannot overcome the SM background with all the versatile kinematical cuts applied in 97, and therefore has no observational prospects. On the other hand, it has been shown that the $S$-pair production, even having a smaller production cross section, may get larger than the background in the 4$b$-tagged final-state jets with a cut $P_T \geq 800$ GeV.

Repeating the analysis made for the previous model, we find masses $m_{\Phi_7}$ compatible with the proton decay constraints.
$m_G \geq 3 \times 10^{15}\text{GeV}$. As shown in Fig. 1, we have $2\text{TeV} < m_{\Phi_7} \lesssim 10^{11}\text{GeV}$.

Figure 1: The parameter space passing the conditions (i)-(iv) in Sec. V. The region compatible with the proton decay constraints $m_G \geq 3 \times 10^{15}\text{GeV}$ is explicitly shown in light blue. The upper two panels correspond to Model (1) and the lower one to Model (2) considered in the text. In the latter case, the mass of the extra scalar electroweak doublet $\Phi_1$ is fixed at 2 TeV.

Let us note also that, even if we fix the mass of all the scalars at 2 TeV and the seesaw mediators at $10^{14}\text{GeV}$, as is done for the models in Table V, the GUT scale is still high enough to be safe, facing new possible improvement of the proton decay constraints in the future experiments. Now, as with Model (1), we consider the constraints imposed on the present model by the interpretation of the $\Xi_3$ as a CDM candidate. As we discussed above, this requires that $m_{\Xi_3} \sim 2.5\text{ TeV}$. Scanning the parameter space, as with Model (1), we find the plot shown in the right panel of Fig. 2, from which we derive the lower bound $m_S \gtrsim 10^{12}\text{ GeV}$.

Figure 2: Dark matter constraints: allowed parameter space in $m_S$ and $m_{\Xi_3}$. The left and right panels correspond to Models (1) and (2), respectively.
VI. CONCLUSIONS AND DISCUSSION

We proposed a version of the adjoint $SU(5)$ grand unification model with an extra $T_7 \otimes Z_3 \otimes Z_3 \otimes Z_4 \otimes Z_2' \otimes Z_{12}$ flavor symmetry, which successfully describes the SM fermion mass and mixing pattern. The model has in total 16 effective free parameters, from which 2 are fixed and 14 are fitted to reproduce the experimental values of 18 observables in the quark and lepton sectors i.e., 9 charged fermion masses, 2 neutrino mass-squared splittings, 3 lepton mixing parameters, 3 quark mixing angles, and 1 CP-violating phase of the CKM quark mixing matrix. The observed hierarchy of charged fermion masses and quark mixing angles is a consequence of the $Z_3 \otimes Z_4 \otimes Z_{12}$ symmetry breaking, triggered by the $SU(5)$ scalar singlets $\sigma$, $\tau$, and $\varphi$, charged under this symmetry, and which acquire VEVs at very high-energy scale, close to the GUT scale. The non-SM fermion spectrum of our model is composed of a single heavy $SU(5)$ singlet right-handed Majorana neutrino $N_R$ and two more fermionic fields: an electroweak singlet $\rho_0$ and triplet $\rho_3$, both from the adjoint 24 irrep of $SU(5)$. Thus the light neutrino masses arise in our model from type-I and type-III seesaw mechanisms mediated by these fields. The smallness of neutrino masses is a consequence of their inverse scaling with respect to the masses of these three seesaw mediators as well as the quadratic proportionality to the presumably small neutrino Yukawa couplings. The model predictions for the physical parameters in the quark and lepton sectors are in good agreement with the experimental data. The experimentally observed deviation from the trimaximal pattern is implemented by introducing two $T_7$ triplet scalars $\chi$ and $\xi$, singlets under $SU(5)$. The model predicts an effective Majorana neutrino mass, relevant for neutrinoless double beta decay, with values $m_{\beta\beta} = 4$ and 50 meV, for the normal and the inverted neutrino spectrum, respectively. In the latter case, our prediction is within the declared reach of the next-generation bolometric CUORE experiment [65] or, more realistically, of the next-to-next-generation tone-scale $0\nu\beta\beta$-decay experiments.

According to our model, the leptonic Dirac CP-violating phase is vanishing. In view of the current experimental trend, it could get into tension with the observations. The latest fit of the neutrino oscillation experimental data by the Valencia group, Ref. [8], indicates a nonvanishing CP-violating phase at the 1 $\sigma$ (less than 2 $\sigma$) level for the normal (inverted) neutrino mass hierarchy. The Bali group in their fits claims slightly larger significance, but also below the $3 \sigma$ level [69]. Thus, with the current experimental significance, essentially below than the golden 5 $\sigma$, our model is not yet in trouble with the CP. On the other hand, we are aware of the necessity of reconsidering this aspect of our approach, which will be done elsewhere.

In the last section of this paper, we studied the compatibility of our model with certain physical conditions expected from a plausible GUT model. Among them we considered the gauge coupling unification, the proton stability constraints, the smallness of the active neutrino masses, and nontrivial LHC phenomenology. Towards this end, we specified the simplest benchmark models of the non-SM particle spectrum lighter than the GUT scale and which meet these conditions. We examined two of them and found that they may give rise to observable signals at the LHC, as specified the simplest benchmark models of the non-SM particle spectrum lighter than the GUT scale and which meet these conditions.

In this work, we also considered the field $\rho_3$ as the lightest component of the 24, and therefore, the baryogenesis can be accomplished in our model in the same way. Note also that in this mechanism [100], the decays of the $\rho_3$ create a lepton asymmetry, which then is converted in a baryon asymmetry by the sphalerons. Imposing the condition of the successful leptogenesis and for the normal hierarchy of neutrinos, one finds that the mass of $\rho_3$ should be large, which is in agreement with the large $\rho_3$ mass values predicted in the present paper.

Finally, as was previously noticed in Ref. [43], the mass of $\rho_3$ must be heavier than $10^6$ GeV $- 10^7$ GeV in order to satisfy the constraints from the big bang nucleosynthesis for the GUT scales larger than $3 \times 10^{15}$ GeV. This condition is also consistent with our results, where the mass of this field is set around the GUT scale.

Appendix A: The product rules for $T_7$

The group $T_7$ is the minimal non-Abelian discrete group having a complex triplet. The discrete group $T_7$ has 21 elements and 5 irreps, i.e., one triplet $3$, one antitriplet $\bar{3}$, and three singlets $1_0$, $1_1$ and $1_2$ [12]. Furthermore, the $T_7$ group is a subgroup of $SU(3)$ and $\Delta(3N^2)$ with $N = 7$ and is isomorphic to $Z_7 \times Z_3$. The triplet and antitriplet irreducible representations can be defined as follows [12]:

\[ 3 \equiv \begin{pmatrix} x_1 \\ x_2 \\ x_4 \end{pmatrix}, \quad \bar{3} \equiv \begin{pmatrix} x_{-1} \\ x_{-2} \\ x_{-4} \end{pmatrix} = \begin{pmatrix} x_6 \\ x_5 \\ x_3 \end{pmatrix}. \tag{A1} \]

The triplet and antitriplet $T_7$ tensor irreducible representations satisfy the following product rules:

\[
\begin{pmatrix} x_1 \\ x_2 \\ x_4 \end{pmatrix} \otimes \begin{pmatrix} y_1 \\ y_2 \\ y_3 \end{pmatrix} = \begin{pmatrix} x_2y_1 \\ x_1y_1 \\ x_4y_3 \end{pmatrix} \oplus \begin{pmatrix} x_4y_2 \\ x_1y_4 \end{pmatrix} \oplus \begin{pmatrix} x_2y_1 \\ x_2y_2 \end{pmatrix}, \tag{A2}
\]

\[
\begin{pmatrix} x_6 \\ x_5 \\ x_3 \end{pmatrix} \otimes \begin{pmatrix} y_6 \\ y_5 \\ y_3 \end{pmatrix} = \begin{pmatrix} x_5y_3 \\ x_3y_6 \end{pmatrix} \oplus \begin{pmatrix} x_3y_5 \\ x_3y_3 \end{pmatrix} \oplus \begin{pmatrix} x_5y_5 \\ x_5y_5 \end{pmatrix}, \tag{A3}
\]

\[
\begin{pmatrix} x_1 \\ x_2 \\ x_4 \end{pmatrix} \otimes \begin{pmatrix} y_6 \\ y_5 \\ y_3 \end{pmatrix} = \begin{pmatrix} x_2y_6 \\ x_1y_5 \\ x_4y_3 \end{pmatrix} \oplus \begin{pmatrix} x_1y_5 \\ x_2y_3 \end{pmatrix} \oplus \begin{pmatrix} x_1y_3 \\ x_4y_6 \end{pmatrix} \oplus \sum_{k=0,1,2} (x_1y_6 + \omega^k x_2y_5 + \omega^{2k} x_4y_3) \cdot 1_k. \tag{A4}
\]

Whereas the tensor products between singlets are given by the relations

\[
(x)_{1_0}(y)_{1_0} = (x)_{1_1}(y)_{1_2} = (x)_{1_2}(y)_{1_1} = (xy)_{1_0},
\]

\[
(x)_{1_1}(y)_{1_1} = (xy)_{1_2},
\]

\[
(x)_{1_2}(y)_{1_2} = (xy)_{1_1}, \tag{A5}
\]

the product rules between triplets and singlets read

\[
(y)_{1_1} \otimes \begin{pmatrix} x_{1(6)} \\ x_{2(5)} \\ x_{4(3)} \end{pmatrix}_{3(\bar{3})} = \begin{pmatrix} yx_{1(6)} \\ yx_{2(5)} \\ yx_{4(3)} \end{pmatrix}_{3(\bar{3})}. \tag{A6}
\]

where $\omega = e^{i\frac{2\pi}{3}}$. The representation $1_0$ is trivial, while the nontrivial $1_1$ and $1_2$ are complex conjugate to each other. Some reviews of discrete symmetries in particle physics can be found in Refs. [11] [12] [39] [101].

Appendix B: On the universality of Yukawa couplings

The aforementioned scheme of approximate universality of dimensionless couplings can be justified by adding an extra $Z_{24}$ symmetry and four $SU(5)$ scalar singlets, assigned as $T_7$ trivial singlets, as well as by setting their VEVs to be equal to $\lambda \Lambda$, with $\lambda = 0.225$, one of the Wolfenstein parameters, and $\Lambda$ being our model cutoff. One of the four $SU(5)$ scalar singlets, namely $S$, can be assumed to have the same $Z_{12}$ charge as the scalar field $\sigma$ of our model and can also be made charged under the new $Z_{24}$ symmetry and neutral under the remaining cyclic symmetries. The remaining three $SU(5)$ scalar singlets, namely $\Delta_i$ ($i = 1, 2, 3$), can be assumed to be only charged under the new $Z_{24}$ symmetry. These four new scalar fields will transform under the $Z_{24}$ symmetry as follows:

\[
S \rightarrow e^{-i \Delta S}, \quad \Delta_1 \rightarrow i \Delta_1, \quad \Delta_2 \rightarrow e^{i \Delta_2}, \quad \Delta_3 \rightarrow e^{i \Delta_3}. \tag{B1}
\]
The aforementioned $Z_{24}$ charge assignments will generate the following $Z_{24}$ neutral combinations of the new scalar fields:

$$S^6\Delta^2_1, S^4\Delta^2_2, S^3\Delta^2_3.$$ (B2)

These $Z_{24}$ neutral combinations will give rise to the following Yukawa operators invariant under the symmetries of the model:

$$\varepsilon_{ijklp}q^{(1)}_{ij}H_p^{(2)}\psi_{kl}^{(1)}S^6\Delta^2_1, \varepsilon_{ijklp}q^{(2)}_{ij}H_p^{(3)}\psi_{kl}^{(2)}S^4\Delta^2_2, \varepsilon_{ijklp}q^{(1)}_{ij}H_p^{(3)}\psi_{kl}^{(3)}S^3\Delta^2_3, \varepsilon_{ijklp}q^{(3)}_{ij}H_p^{(3)}\psi_{kl}^{(1)}S^3\Delta^2_3.$$ (B3)

The first two aforementioned Yukawa operators will contribute to the 11 and 22 entries of the up-type quark mass matrix, whereas the last two operators will contribute to the 13 and 31 entries. These new contributions will be proportional to $\lambda^8$, $\lambda^6$, and $\lambda^5$, respectively, and thus will introduce deviations from the exact universality in the dimensionless Yukawa couplings. These aforementioned contributions will correspond to the first-order term in the $\lambda$ expansion of the expressions given in Eq. (41).

**Appendix C: Simple benchmark models**

The contributions to the $\Delta b'$ coefficients for each field in the $5_s$, $24_s$, $45_s$, and $24_f$ reps are shown in Table IV. In Table V the configurations which generate neutrino mass in agreement with the mechanism described in Sec. III are shown. Each particle content, added to the SM, lead to "SM+X" configurations unifying gauge couplings almost equal to or better than the MSSM, i.e, each one of the simplest configurations satisfies: $\alpha_s^{-1}(m_G) - \alpha_{1}^{-1}(m_G) \lesssim \alpha_{2MSSM}^{-1}(m_G) - \alpha_{1MSSM}^{-1}(m_G)$ and $3 \times 10^{15}$ GeV $\lesssim m_G \lesssim 10^{18}$ GeV in order to obtain proton lifetimes allowed by the actual experimental bounds.

| SU(5) Rep | Fields | $\Delta b_{1/2/3}$ |
|----------|--------|-----------------|
| $\delta_5$ | $H_1, H_2$ | $\left( \frac{1}{2}, \frac{1}{2}, 0 \right), \left( \frac{1}{2}, 0, \frac{1}{2} \right)$ |
| $24_{s5}$ | $\Xi_1, \Xi_2, \Xi_3, \Xi_4, \Xi_5, \Xi_6, \Xi_7, \Xi_8, \Xi_9$ | $\left( 0, 0, 0 \right), \left( 0, 0, 0 \right), \left( 0, 0, 0 \right), \left( \frac{1}{2}, 0, \frac{1}{2} \right), \left( \frac{1}{2}, 0, \frac{1}{2} \right), \left( \frac{1}{2}, 0, \frac{1}{2} \right), \left( \frac{1}{2}, 0, \frac{1}{2} \right), \left( \frac{1}{2}, 0, \frac{1}{2} \right)$ |
| $45_{s5}$ | $\Phi_1, \Phi_2, \Phi_3, \Phi_4, \Phi_5, \Phi_6, \Phi_7 | $\left( \frac{1}{2}, 0, \frac{1}{2} \right), \left( 0, 0, 0 \right), \left( 0, 0, 0 \right), \left( \frac{1}{2}, 0, \frac{1}{2} \right), \left( \frac{1}{2}, 0, \frac{1}{2} \right), \left( \frac{1}{2}, 0, \frac{1}{2} \right), \left( \frac{1}{2}, 0, \frac{1}{2} \right), \left( \frac{1}{2}, 0, \frac{1}{2} \right)$ |
| $24_{f}$ | $\rho_1, \rho_2, \rho_3, \rho_4, \rho_5, \rho_6, \rho_7$ | $\left( 0, 0, 0 \right), \left( 0, 0, 0 \right), \left( 0, 0, 0 \right), \left( \frac{1}{2}, 0, \frac{1}{2} \right), \left( \frac{1}{2}, 0, \frac{1}{2} \right), \left( \frac{1}{2}, 0, \frac{1}{2} \right), \left( \frac{1}{2}, 0, \frac{1}{2} \right), \left( \frac{1}{2}, 0, \frac{1}{2} \right)$ |

Table IV: Contribution to the running of the gauge couplings of the fields from the $5_s$, $24_s$, $45_s$, and $24_f$ representations of the SU(5). The seesaw particles mediate $N_2$ and $p_{0,3}$ are added at the $10^{18}$ GeV, contributing to the running of the gauge couplings with $(0, 4/3, 0)$ in the range $[10^{14} GeV, m_G]$. The contribution of the fields in the $24_f$ is twice the contribution of $24_s$ owing its fermionic nature.
