Abstract

The rat represents an important animal model that, in many respects, is superior to the mouse for dissecting behavioral, cardiovascular and other physiological pathologies relevant to humans. Derivation of induced pluripotent stem cells from rats (riPS) opens the opportunity for gene targeting in specific rat strains, as well as for the development of new protocols for the treatment of different degenerative diseases. Here, we report an improved lentivirus-based hit-and-run riPS derivation protocol that makes use of small inhibitors of MEK and GSK3. We demonstrate that the excision of proviruses does not affect either the karyotype or the differentiation ability of these cells. We show that the established riPS cells are readily amenable to genetic manipulations such as stable electroporation. Finally, we propose a genetic tool for an improvement of riPS cell quality in culture. These data may prompt riPS cell-based gene targeting in rat as well as the development of iPSC cell-based therapies using disease models established in this species.

Introduction

For more than a century the rat has been an important animal model, which is superior in many respects to the mouse, for example for behavioral, cardiovascular and other physiological studies. Numerous inbred and outbred rat strains are used in different fields of research, and transgenic technologies are well developed in this species. However, until recently, gene targeting was not available in rats because ES cell derivation from pre-implantation rat embryos repeatedly failed [1,2,3]. This led to the mouse being used as the sole animal model for ES-cell based gene targeting techniques and for the establishment of tissue replacement therapies. A recent breakthrough finally allowed this target to be overcome. It was shown that serum-free defined culture conditions were also demonstrated to be beneficial for the establishment of tissue replacement therapies. A recent breakthrough finally allowed this problem to be overcome. It was shown that serum-free defined culture medium (N2B27) in conjunction with inhibition of the MEK (mitogen activated protein kinase)/ERK (extracellular signal regulated kinases 1 and 2) pathway and glycogen synthase kinase-3 (GSK3) by the small synthetic drugs PD0325901 and CHIR99021, respectively, in combination with activation of the LIF/STAT3 pathway (N2B27+2i+LIF), are required and sufficient to set and maintain the so-called “ground state” of pluripotent stem cells [4]. This empirical observation allowed ES cell line derivation from previously non-permissive mouse strains, such as NOD mice [5,6] and ultimately, after 20 years of unsuccessful attempts, from rats [7,8]. The established cell culture conditions were also demonstrated to be beneficial for the establishment and maintenance of pluripotent cells from various species including rat and human [4,6,7,9,10].

Induced pluripotent stem (iPS) cells are derived from somatic cells reprogrammed to the pluripotent state by the induced expression of defined transcription factors, achieved for the first time by the seminal work of Takahashi and Yamanaka [11]. This new type of pluripotent cells has offered new exciting options in regenerative medicine allowing the replacement of cells and organs with the patient’s own cells thereby avoiding immunological complications. In order to develop such technologies in approved animal models, iPS cells were also generated from rodents. Despite numerous papers published describing mouse iPS cells, very few groups reported the derivation of iPS cells from rat (riPS). Interestingly, whereas inhibition of GSK3 and MEK/ERK pathway was found to be critical for the survival and maintenance of pluripotency in riPS cells in some studies [8,12,13,14], the derivation of riPS cells using classical serum- and LIF-containing mouse ES medium was also reported [15].
In this study, we applied the four reprogramming factors [11] to derive iPSCs from rat embryonic fibroblasts (REF) using different cell culture conditions. We report an improved protocol for the generation and maintenance of these cells using small inhibitors of the MEK/ERK pathway and GSK3. In addition, we present a method suitable for their genetic modification by stable transfection and propose a genetic tool for an improvement of iPSC cell quality in culture.

Materials and Methods

Ethics statement

All animal procedures were performed according to the guidelines for the humane use of laboratory animals, with standards corresponding to those prescribed by the American Physiological Society. The teratoma formation and iPSC cell injection into rat preimplantation embryos with subsequent analysis of chimeric embryos were performed in the Institute of Cytology strictly in agreement with the animal protection legislation acts of the Russian Federation and was approved as humane use of laboratory animals by the Institute’s Ethical Board. The isolation of rat embryonic fibroblasts (REF) was performed using naturally mated animals which were sacrificed using a UK Home Office ‘Schedule 1’ procedure which does not require specific ethical approval.

Plasmids and lentiviruses

To induce pluripotency lentiviruses (human immunodeficiency virus (HIV)-based retroviruses), encoding pluripotency factors Oct4, Sox2, cMyc, and Klf4 were generated. To this end, full-size cDNAs of corresponding genes were amplified by PCR from reverse-transcribed mouse ES cell polyA RNA and cloned in place of the EGFP gene (Figure S3A) within the lentiviral vector LVTTHM provided by Didier Trono [16]. 293T cells were transfected with envelope-encoding pMD2G (5 mg), packaging pCMV-dR8.74PA2 (5 mg), and either Oct4-, Sox2-, Klf4-, or cMyc-encoding LVTTHM-based plasmids (20 mg) by calcium-phosphate method. Lentiviruses in cell culture supernatant were collected and prepared as described elsewhere [16].

Thymidine kinase (TK) gene was PCR amplified from pKO-NTKV-1907 (Stratagene) and cloned into p2A2Btk-lac plasmid [17] at Ncol/Xhol sites, replacing the lac sequence. The vxsPuro-polyA cassette was subsequently cloned at Xhol/SpeI sites just downstream of the TK gene of the resulting plasmid to obtain the p2A2Btk-TKresPuro vector (Figure S3B).

Cell culture

Unless specified, all cell culture products were from Invitrogen (Darmstadt, Germany). Mouse and rat embryonic fibroblasts (MEF and REF, respectively) were routinely maintained in high glucose DMEM supplemented with 10% FBS (Sigma-Aldrich, St. Louis, MO), 100 U/ml penicillin, 100 µg/ml streptomycin, 2 mM L-glutamine, 1x non-essential amino acids, 50 µM β-mercaptoethanol. MEFs were inactivated by cultivation in cell culture media (DMEM/F12 supplemented with 1x N2, 100 U/ml penicillin, 100 µg/ml streptomycin, 0.005% BSA, 25 µM β-mercaptoethanol) and B27 media (NB M supplemented with 1x B27 (without RA), 100 U/ml penicillin, 100 µg/ml streptomycin, 2 mM L-glutamine, 25 µM β-mercaptoethanol). When indicated, media were supplemented with 300 U/ml LIF (PAA, Pasching, Austria), 3 µM GSK3 inhibitor CHIR99021 (Axon, Groningen, Netherlands), 1 µM MEK inhibitor PD0325901 (Axon), 0.5 µM A-83-01 (Tocris Bioscience, Missouri, USA).

Derivation of iPSCs

To isolate REs naturally mated Fischer344 female rats were checked for the presence of a vaginal plug and thereafter sacrificed at day 14 of pregnancy (E14). Isolated embryos were freed from head and visceral tissues, minced, subsequently trypsinized and plated on tissue culture dishes (passage 0). REs at passage 3 were seeded at 1.5×10^4 cells/cm² in a 6-well plate and transduced 24 hrs later with the LVTTHM-based Oct4, Sox2, Klf4, cMyc, and EGFP lentiviruses (see above). Four days later cells were split onto a 10 cm culture dish (Falcon), containing mitomycin-inactivated MEFs and cultured in one of the three reprogramming media (see above). After 10–12 days, iPSC cell colonies were picked, dissociated in TrypLE-express, and expanded on MEF-feeder cells in the respective reprogramming medium.

Maintenance and electroporation of iPSCs

iPSCs were routinely maintained on mitomycin-treated MEFs in N2B27+2i+LIF media. Cells grew as round, compact colonies, which tended to detach after 2–3 days in culture. Cells were routinely replated every 3–5 days using TrypLE-express. Depending of the proportion of attached cells, iPSC cells were either trypsinized on the plate, or collected from the supernatant, centrifuged, and dissociated in suspension. This procedure allowed removal of dead feeder cells as well as differentiated iPSC cells, which were usually stably attached to the substrate. For stable transfection, iPSC cells were harvested with TrypLE-express, and subsequently co-electroporated (5×10^6 cells, 240 V, 500 µF) with 25 µg of circular pMC-Cre (kindly provided by K. Rajewsky) and linearized p2A2B-tk-TkresPuro plasmids (7:1 molar ratio). Puromycin (2 µg/ml) was added 48 hrs later for 3 days; clones were picked 10 days after electroporation into 96-well plates and genotyped by PCR, using primers specific for exogenous Oct4, Klf4, Sox2, cMyc, and EGFP and for the p2A2B-tk-TkresPuro cassette (primer sequences are listed in the Table S3). Three subclones, derivatives of the clone IIIB9 were chosen for further analysis. iPSC cells harboring the p2A2B-tk-TkresPuro cassette were occasionally cultured in the presence of 1 µg/ml puromycin (usually for 3 days every 4–5 passages).

iPSC cell karyotyping

Six primary male iPSC cell clones, selected by Y-chromosome-specific PCR of genomic DNA, and three sub-clones after Cre-mediated lentivirus excision, were subjected to karyotyping procedure as follows. Exponentially growing iPSC cells were incubated for 1 hr with 5 µg/ml ethidium bromide, then for 1.5 hrs with 0.5 µg/ml colchicine. Cells were next harvested with TrypLE and incubated for 20 min at 37°C in 0.075 M KCl solution, fixed in methanol/acetic acid (3:1), placed on pre-wet chilled microscope slides, air-dried, stained for 5 min either with Giemsa stain or with 200 ng/ml 4′,6-diamidino-2-phenylindole (DAPI) in 2xSSC buffer. Slides were rinsed with 2xSSC and distilled water, then embedded under coverslips into antifading solution (Vector). DAPI-stained chromosomes were identified as described elsewhere [18]. Giemsa-stained metaphase spreads
(90–140) were used for chromosome counts and polyploid cells determination. To identify chromosomes from 9 to 66 DAPI stained metaphase plates were analyzed. From 9 to 40 metaphase spreads were examined in clones containing from 30 to 50 percent of polyploid cells. DAPI-stained metaphase spreads were analyzed using the AxioPlan 2 Imaging microscope (Zeiss, Germany) equipped with CCD camera (CV M300, JAI Corporation, Japan), CHROMA filter sets and ISIS4 image-processing package of MetaSysteme GmbH at the Center for Joint Ownership for Microscopic Analysis SB RAS (ICG SB RAS, Novosibirsk).

Immunocytochemistry and alkaline phosphatase staining

Cells were fixed in 4% paraformaldehyde (Sigma) and stained with antibodies against Oct4 (sc-5279, Santa Cruz Biotechnology Inc), SSEA-1 (MC-980, Developmental Studies Iowa Hybridoma Bank), Nanog (REC-RCAB0002P-F, COSMHO BIO CO, Tokyo, Japan), and neuronal class III β-Tubulin (TUJ1) (MMS-435P, Covance), as described elsewhere [19]. Immunostained cells were examined either on a fluorescent microscope Leica DM6000 with 5x, 10x, 20x, and 40x air objectives or a confocal Leica TCS SP5 software. For the alkaline phosphatase (AP) staining, cells were fixed with 4% paraformaldehyde, washed with Tris-maleate buffer pH 9.0, and then subsequently incubated for 30 minutes in Tris-maleate buffer, 4 mM MgCl₂, 0.4 mg/ml N-AS-MX (Sigma), 1 mg/ml Fast Red TR Salt (Sigma). Once red colonies were detected the reaction was stopped by removing colored solution and adding PBS, pH 7.4.

Clonability assay

To evaluate the effect of different small molecules on maintaining the self-renewal riPS cells were trypsinized into single cells and seeded at the density of 50 cells/cm² in a 6-well plate on mitomycin-treated MEFs. Cells were cultured for 5 days in N2B27 media containing different combinations of inhibitors and subsequently fixed and subjected to the AP staining. Each media containing different combinations of inhibitors and mitomycin-treated MEFs. Cells were cultured for 5 days in N2B27 medium. 6–8 days later differentiated cells were either harvested and transferred onto Matrigel-coated dishes, approximately 10–12 embryoid bodies per 1-well of a 6-well plate in N2B27 medium and kept on ice until the injection.

**Results and Discussion**

To derive rat iPS (riPS) cells, rat embryonic fibroblasts (REFs) were transduced with Oct4, Sox2, Klf4, cMyc and, for visualization, with EGFP-encoding lentiviruses (OKSM+G) and then plated at a low density on mitomycin-inactivated mouse embryonic fibroblasts (MEF) feeder layer in media permissive for the propagation of iPS
cells. In the first set of experiments we applied the original cell culture conditions, described for mouse iPS cell derivation [11] using serum- and LIF-containing medium. However, in contrast to previously reported success in riPS cell derivation using similar transduction and cell culture systems [15], this approach did not result in any viable riPS cell colonies (Table 1).

Taking into account the recent success in the generation of rat ES cells [7,8], we then applied the N2B27 +2i +LIF culture conditions and achieved a robust derivation of riPS cells from REFs with the help of (OKSM +G) lentiviral vectors (Table 1, Figure 1A, Figure S3A). The inclusion of the cMyc virus, although beneficial for the efficiency of riPS cell derivation, was not obligatory (data not shown). We next compared the N2B27+2i+LIF with previously reported most efficient riPS cell-derivation medium containing serum replacement (SR), same MEK and GSK3 inhibitors (2i), LIF, and additionally, the activin receptor-like kinase (ALK5) inhibitor A-83-01 [14]. The numbers of primary riPS cell colonies were slightly higher in the SR-based medium, however, the percentage of surviving clones following 2 subsequent passages was 71% in the N2B27-based vs. 25% in the SR-based medium, respectively (Table 1).

Upon derivation eight individually picked clones, reprogrammed in N2B27+2i+LIF conditions were propagated to establish riPS cell lines. Cells were routinely maintained on inactivated MEFs in N2B27+LIF medium. Rat iPS cells typically grew as compact clumps that tended to detach from

---

**Table 1. Efficiencies of riPS cell derivation in different culture conditions.**

| Reprogramming Medium | References | Reprogramming efficiency | Total N of picked clones | Total N of survived clones | Survival rate after 2 passages |
|----------------------|------------|--------------------------|--------------------------|----------------------------|-------------------------------|
| 1 DMEM + 15% FCS +LIF [11,15] | 0 | 0 | |
| 2 DMEM + SR +2i + LIF + A-83-01 [14] | 8.9±1.3×10⁻⁴ | 48 | 37 | 25.0±12.5% |
| 3 N2B27 +2i +LIF [7] | 5.4± 0.9×10⁻⁵ | 48 | 12 | 70.8±6.3%* |

To derive rat iPS (riPS) cells 1.5×10⁶ REFs were transduced with the LVTHM-based Oct4, Sox2, Klf4, cMyc, and EGFP lentiviruses. Four days later cells were split onto a 10 cm culture dish and cultured in one of the three reprogramming media. After 10–12 days, primary riPS cell colonies were counted to calculate the reprogramming efficiency. Survival rate was calculated as a relation between the number of picked and the number of surviving clones after 2 passages. *p<0.05, Student’s t-test condition 3 vs condition 2, [DMEM + SR +2i + LIF + A-83-01] N = 3, [N2B27+2i+LIF]: N = 4 independent experiments.

**Figure 1. Generation of rat iPS (riPS) cells.** (A) Rat embryonic fibroblasts (REFs) (left), primary riPS cell colony derived thereof after transduction with lentiviruses expressing Oct4, Klf4, Sox2, cMyc, and EGFP with some satellite colonies (middle), and riPS cell line after several passages in N2B27+LIF+2i medium (right). (B) Karyotyping results of the G4 riPS cell clone, in which 90% of metaphase plates showed the normal male chromosomal content (42,XY). (C) Cre-mediated excision of the proviruses in riPS cell clones H5, G3, and G4 from the genome of the parental IIIB9 riPS cell clone, shown by PCR of genomic DNA with primers specific for exogenous Oct4, Klf4, Sox2, cMyc, and EGFP sequences. PCR for the Y-chromosome specific gene Sry confirmed the DNA integrity and male origin of riPS clone IIIB9. (D) Cre-mediated excision of EGFP-lentivirus visualized in G3 riPS cell clone under fluorescent microscope.

doi:10.1371/journal.pone.0027345.g001
substrate as colonies expanded, resembling in this respect rat ES cells [8]. However, after rounds of trypsinization and passaging, riPS cells changed their morphology, and flat and more adhesive colonies appeared. These features make riPS cells notably different from those of mouse origin. Also noticeable, primary riPS cell colonies were frequently surrounded by small satellite colonies (Figure 1A, central panel). With respect to these unusual morphological characteristics, it would be of interest to compare, for example, properties and expression levels of matrix adhesion molecules in iPS and ES cells of both species.

Immunostaining for the pluripotency markers revealed that riPS cells are positive for Oct4, Nanog, SSEA1 and alkaline phosphatase (Figure 2A and Figure S4 A–C). Interestingly, despite the presence of inhibitors which were shown to have a beneficial effect on Nanog expression in mouse ES cells [23], in analysed riPS cell lines Nanog showed a variable expression pattern, consistent with previous observations in mouse ES cells grown in serum-containing medium [24]. Further analysis showed that riPS cells were able to form embryoid bodies and give rise to derivatives of all three germ layers in course of in vitro differentiation (Figure S4D). The clonability assay showed that riPS cell proliferation and survival were severely compromised in the absence of GSK3 inhibitor CHIR99021, whereas omission of PD0325901 and LIF from the culture medium led to the quick differentiation of riPS cells (Table S1; Figure S2). Such a tight dependence upon the two inhibitors and LIF during the derivation and maintenance indicates that the newly obtained riPS cells are in the ground state of pluripotency [4,7].

Because male ES cells are strongly preferred for gene targeting in mouse, we reasoned that the same would apply to the rat iPS cells. Thus we determined gender of primary riPS cell clones by PCR with Sry-specific primers (Table S3 and data not shown). Six selected clones were further karyotyped as shown in Figure 1B and Table 2. All, except IIIA10, is likely to be a mixed clone, were confirmed to be XY. A characteristic of all six clones was a high ratio of tetraploid and aneuploid cells (Table 2). The latter cells were predominantly hypoploid with different chromosomes being lost (data not shown). The clone that demonstrated the highest ratio of cells with normal karyotype (IIIB9) was used for subsequent manipulations. Of note, chromosomal instability appears to be a hallmark of cultured ES cells. A recent study reported an amplification of centrosomes, leading to both polyploidization and aneuploidization of human ES cells [25]. Extensive analysis of 540 mouse ES cell lines showed that only 60% possess a normal diploid karyotype and 25% show a loss of the X chromosome [26]. Significant chromosomal instability was also reported for mouse and human iPS cells [11,27,28]. The rate of chromosomal abnormalities may be a consequence of both culture conditions and intrinsic properties of pluripotent cell lines. It is also possible that chromosomal instability is a consequence of the dramatic change in epigenetic state of cells during reprogramming.

Although HIV-derived lentiviruses are considered to efficiently silence the majority of cell types, this is clearly not the case with riPS cells. For example, we observed a high rate of EGFP-encoding lentivirus silencing in newly derived riPS cell clones, which became increasingly obvious with increasing number of passages (Figure S1A–C). The same phenomenon has also been observed in human iPS cells by others [14]. Interestingly, while the silencing appeared in undifferentiated cells, reactivation of lentiviral expression was observed in some spontaneously differentiated cells (Figure S1D, E). Reset of the expression of either Oct4, Sox2, or Klf4 in a subset of riPS cells might have an adverse effect on their further differentiation to specific cell types.
whereas reactivation of the cMyc provirus after its germline transmission has been reported to induce tumor growth [29,30]. Therefore, we set out to delete the proviruses from the genome of the reprogrammed cells, making use of the loxP sites included in the proviral LTRs [16]. To this end, the riPS cell clone IIB9, chosen on the basis of the highest ratio of cells with normal karyotype (Table 2), was co-electroporated with Cre recombinase-encoding pMC-Cre plasmid and linearized p2A2Btk-TKiresPuro plasmid. The latter, besides being useful for an enrichment of Cre-electroporated cells via a rapid puromycin selection, resulted in a dramatic improvement in the quality of riPS cell cultures (see below). Provirus excision was monitored by PCR with primers in a 200-bp fragment containing the TKiresPuro gene, data not shown). To our knowledge, the 2A2Btk moiety represents the shortest known regulatory element sensitive to the differentiation status of ES and iPS cells (via the TK gene, data not shown). The hanging drop method using serum-free medium supplemented with the GSK3 inhibitor CHIR99021 during the first 2 days of differentiation, similar to the approach reported for the rat ES cells [8], allowed us to address the riPS cell viability issue. Thirdly, when injected into the immune-compromised Nude rats or mice, the riPS cell subclones formed teratomas consisting of cell types derived from all three germ layers (Figure 2D). Lastly, riPS cell subclones could efficiently participate in embryonic development following their injection into rat preimplantation embryos (Figure 2E). Out of 11 fetuses analyzed one showed a significant degree (~20%) of chimerism (Table S4). Significant incorporation of differentiated riPS cell descendants into tail, head, liver and kidney was tracked by PCR of genomic DNA using primers specific for the 2A2Btk-TKiresPuro cassette (Figure 2E, Figure S3B). In contrast, very limited contribution to the placenta was detected (Figure 2E), suggesting that riPS cells, like iPS and ES cells of other species, lack the ability to differentiate into the trophoblast cell lineage. Taken together, our data suggest that the newly derived cell lines represent bona fide iPS cells and that Cre recombinase-mediated excision does not produce any obvious chromosomal rearrangements or loss of pluripotency.

Despite of the presence of LIF and both small inhibitors, riPS cells showed some predisposition to spontaneous differentiation in vitro and could be maintained in an undifferentiated state without subcloning only for a limited number of passages. To address this issue, we have developed a transgenic cassette that allowed a selective and efficient elimination of differentiated cells in riPS cell cultures. The 200-bp 2A2B sequence from the distal enhancer of Pou5f1 (Oct4) gene, containing binding sites for Oct4 and Sox2 heterodimers (2B) and a DNA binding element of an unknown transcription factor (2A), has been shown to act synergistically in transient transfection as an ES cell-specific enhancer when coupled to either the homologous Pou5f1 or to a heterologous minimal promoter such as thymidine kinase (Δk) [17]. Our data suggests that the 2A2Btk enhancer/promoter moiety can direct pluripotency-specific expression of transgenes not only transiently, but also when stably delivered to the genome of ES and iPS cells (data not shown). Making use of this property, we placed a two-way selection bicistronic cassette (TKiresPuro) under transcriptional control of 2A2Btk (Figure S3B) and stably delivered the resulting construct into the genome of riPS cells via electroporation. This manipulation, performed in parallel with the transient delivery of Cre recombinase, allowed us to reliably improve, through brief courses of puromycin selection, the quality of riPS cell cultures via an efficient elimination of spontaneously arising differentiated cells (Figure 3). Of note, we found this cassette functioning equally well in mouse iPS cells, as well as in ES cells of both species (data not shown). The cassette also facilitated enrichment for differentiated cells in vitro (via the TK gene, data not shown). To our knowledge, the 2A2Btk moiety represents the shortest known regulatory element sensitive to the differentiation status of ES and iPS cells. In addition, the relatively small size of this cassette allows stable genome integration via lentiviral vectors (data not shown). We have reported in this paper an optimized approach for the derivation of riPS cells which makes use of various previously reported improvements of iPS/ES-related methods. While comparable in term of derivation efficiency, our approach offers a better survivability of picked riPS cell clones after subsequent culturing, compared to the previously published non-excisable lentivirus-based serum-free system [14]. Contrary to yet another report [13], we failed to generate any viable riPS cells using serum-containing culture medium, even with serum, which was well permissive, for instance, for mouse iPS cell derivation (data not shown).

Table 2. Summary of karyotype analysis of established riPS cell lines.

| riPS cell clone/subclone | Karyotypes in diploid cells | % of diploid metaphase | % of aneuploid metaphase | % of polyploidy metaphase |

*Subclones of IIB9 following Cre-mediated lentivirus excision. doi:10.1371/journal.pone.0027345.t002
Despite rapid progress in the development of novel genomic technologies, such as RNA interference [36] and zinc-finger nucleases technologies [37], gene targeting via homologous recombination in ES cells currently remains the most straightforward approach in functional genomics. This approach, however, has not been available for rat until recently, when rat ES cells have been established [7,8], and subsequently shown to be amenable to homologous recombination [10,38]. In this regard, riPS cells may represent a viable alternative to rat ES cells for functional genetics because their derivation, as shown in this and other studies, is rather simple and straightforward and does not require a supply of preimplantation embryos which can be a quite limited for some strains of rat [39] and E.P., unpublished data), relying instead on easily preserved stocks of rat embryonic fibroblasts. In particular, riPS cells can be isolated from the plethora of existing inbred rat models for polygenic diseases [40], such as hypertension, diabetes or epilepsy, and used to elucidate the pathogenetic mechanisms involved in these disorders. Compared to ES cells, riPS cells are preferable for the development of tissue replacement therapies, allowing the isolation of recipient-specific pluripotent cells and overcoming the problem of post-transplantation rejection. Lastly, due to the fact that, to date, models of many human degenerative diseases have been established solely in the rat, riPS cells represent a very attractive tool for the validation of therapeutical applications of iPS cell technologies in preclinical studies.

Supporting Information

**Figure S1 Lentivirus silencing in undifferentiated riPS cells.** (A) riPS cell clone IIIB9 after 22 passages (p22) in culture. Notice round compact, morphologically undifferentiated colonies that have lost EGFP expression. (B) FACs for EGFP+ cells of riPS cell clone IIIB9 p22 (lower panel) and its subclone IIIB9-G3 derived following the excision of proviruses, including EGFP. The latter served as a negative control (upper panel). Similar results were obtained in 2 independent experiments. (C) Real time PCR analysis of sorted cells, showing that EGFP+ riPS cells express high levels of Nanog, confirming the pluripotent state of this cell population. IIIB9: N = 3; EGFP+, EGFP− N = 2. (D) The EGFP− fraction of riPS cells after FACs shows the onset of EGFP expression in some cells already after 1 day in culture. (E) EGFP− fraction cultured for further 4 days shows a substantial number of EGFP+ cells. Note, that most of Oct4+ cells do not express EGFP, whereas some of morphologically differentiated cells became green.

**Figure S2 RiPS cell clonability assay.** Representative images of alkaline phosphatase staining of riPS cells, seeded at a density of 500 cells per well of a 6-well plate and cultured for 5 days in the presence of LIF and 2i (A, B), or in the presence of LIF and CHIR99021 (C, D). 2.5x magnification (A, C). Examples of an undifferentiated colony (B) and of a morphologically differentiated colony with weak AP-staining (D) (20x and 10x magnification, respectively). Similar results were obtained in 2 independent experiments.

**Figure S3 Plasmids and lentiviruses.** (A) Map of the lentiviral vectors used in this study. Oct4, Sox2, Klf4, and cMyc cDNAs were cloned in place of the EGFP cDNA of the LVTHM vector, which is described in greater details in elsewhere (Wiznerowicz and Trono, 2003, J. Virol 77:8957-61). During reverse transcription, the U3 region of the 5’ LTR is synthesized by using its 3’ homologue as a template, which results in a duplication of LoxP site in the provirus integrated in the genome of transduced cells. The part of LTR DNA between the loxP sites is subject to Cre-mediated excision. LTR, ePPT, and WPRE are lentiviral elements required for its integration and expression. (B) Scheme of the 2A2Btk-TkiresPuro cassette (see text for abbreviations). Arrows indicate primers which were used to detect the cassette in the riPS cell transplanted clonse. The same primer pair was employed for the evaluation of % chimerism after injection of riPS H5 cells into rat preimplantation embryos (Figure 2E and Table S4).

**Figure S4 Pluripotency of riPS cells.** Expression of the pluripotency markers Oct4, Nanog, and SSEA-1 in the primary riPS cell clones IVB3 (A) and IVF3 (B) (passage 13), shown by immunochemical staining with respective antibodies. (C)
Alkaline phosphatase staining in the same two clones. (D) RT-PCR analysis of pluripotency (Nanog), ectoderm (NCAM), mesoderm (FLK and AIP), and endoderm (Sox17 and GATA4) lineage marker expression during the time course of differentiation of the same riPS cell clones using embryoid body (EB) protocols. Cells were harvested at the indicated days after the EB formation (D0-D10). Nat1 served as an endogenous mRNA control. NC-negative control.

Table S1 LIF and inhibition of GSK3 and MEK1/ERK signaling are essential for the riPS cell self-renewal. Cells were seeded at a density of 50 cells/cm² in a 6-well plate and cultured in different conditions for 5 days. Total number of surviving colonies, number of undifferentiated (AP-positive) colonies and number of morphologically differentiated colonies were counted. Survival colonies, number of undifferentiated (AP-positive) colonies and number of morphologically differentiated colonies appeared specifically in the absence of PD0325901 (see Figure S2C, D) were counted. *p<0.01, **p<0.001 vs CHIR99021 + PD0325901 + LIF condition (one way ANOVA with Bonferroni’s post test, N = 3 per condition. Similar results were obtained in 2 independent experiments.

Table S2 Summary of subclones derived from riPS cell clone IIIB9 after Cre-mediated excision of proviruses and co-electroporation with 2A2Btk-TKiresPuro cassette.

(DOC)

Table S3 List of primer pairs used in this study.

(DOC)

Table S4 Real time PCR analysis of E18 chimeric embryos. RiPS cells, harboring 2A2Btk-TKiresPuro cassette in their genome (clone H5) were injected into 8-cell rat embryos. DNA isolated from fetuses at E18 was analyzed by real time PCR using a primer pair specific for the 2A2Btk-TKiresPuro cassette (Table S3 and Figure S3B) normalized to the rat angiotensinogen (AOGEN) gene (this gene is present in both host embryo and incorporated riPS cells). H5 – riPS cell clone used for the injection, 12 – positive E18 fetus. T – tail, L – liver, H – head, K – kidney, P – placenta.

Acknowledgments

We are grateful to Fuyuki Ishikawa (p2A2Btk-hc), Klaus Rajewsky (pME- Cea), Didier Trono (pLVTHM, pP Pax2, and pMD2) for providing valuable reagents, and Audrey Peter for the provision of REE. We thank Susanne da Costa Goncalves for the excellent technical support; the Confocal and 2-Photon Microscopy Core Facility (MDC) staff, Drs. Anje Sporbert and Zoltan Csereysem for their technical assistance and overall imaging support; the FACS Core Facility (MDC) staff, Dr. Hans Peter Rahn for cell sorting; and Sebastian Auer for the help in establishment of the S2 facility.

Author Contributions

Conceived and designed the experiments: AT NA IC NSZ. Performed the experiments: ML IC AR DS EP VM JMM NA. Analyzed the data: ML IC AR DS EP VT VM JMM NA. Contributed reagents/materials/analysis tools: JJM. Wrote the paper: AT NA. Final approval of the manuscript: NA MB AT IC JJM.
