(Received: 11 April 2020; accepted: 11 May 2020)

Researches have demonstrated the ability of probiotic microorganisms to prevent and treat ailments especially those associated with the gastrointestinal tract. Probiotics like Lactobacillus spp. have also displayed the property of bioremediation of heavy metals under in vitro as well as in vivo conditions. The aim of this study was to assess the effects of chromium, lead, cadmium and nickel stress on the properties of B. clausii, a probiotic species of genus Bacillus. The minimum inhibitory concentration (MIC) of the organism under test was determined for Cr (VI), Pb (II), Cd (II) and Ni (II), followed by assessment of morphological and biochemical properties of the B. clausii, antibiotic sensitivity and probiotic efficacy by acid and bile tolerance assays. B. clausii exhibited exceptionally high MICs for the tested heavy metals. The organism did not exhibit any change in its morphological and biochemical characteristics after exposure to heavy metal stress. This stress also did not affect the test organism’s probiotic behaviour as assessed by acid and bile tolerance assays where it showed maximum growth at 3 hrs. for pH 3 and 0.3% bile concentration, respectively. However, after exposure to the four heavy metals, B. clausii showed a tremendous increase in its antibiotic sensitivity. The above study has indicated the capacity for B. clausii to survive in and tolerate high levels of Cr (VI), Pb (II), Cd (II) and Ni (II) while showing no change in its characteristics. Therefore, B. clausii appears to be an ideal candidate for potential bioremediation of Cr (VI), Pb (II) Cd (II) with Pb (II), Cd (II) and Ni (II), in vivo.

Keywords: Bioremediation; Bacillus clausii; Heavy Metals; MIC; Probiotic.
effects of probiotics include improvement of gut health, reduction in symptoms of Irritable Bowel Syndrome (IBS)\textsuperscript{4}, antibiotic associated diarrhoea\textsuperscript{5,6}, infectious diarrhoea caused by rotavirus\textsuperscript{7,8}, traveller’s diarrhoea\textsuperscript{9} and necrotizing enterocolitis\textsuperscript{10}.

Many studies have been performed on bioremediation of heavy metals by microorganisms\textsuperscript{12-14} and have reported an interesting observations that probiotics such as \textit{Lactobacillus} spp. and \textit{Bacillus} spp. also have the ability to bioremediate heavy metals\textsuperscript{15-19}. This has been attributed to the structural components of their cell wall such as teichoic acid, lipoteichoic acid and peptidoglycan\textsuperscript{20}.

Heavy metals such as lead, chromium, nickel, cadmium, mercury and arsenic reach human gut through food and water laden with them. These heavy metals enter the food chain as a result of anthropogenic activities and cause varying levels of toxicity in humans\textsuperscript{21}. Hence, these microorganisms are the best and most effective agents to reduce toxicity caused by heavy metals since they are safe in terms of human usage, are ingested via diet, show gut remediation and can eliminate the heavy metals by defaecation\textsuperscript{22}.

In this study, \textit{B. clausii} was evaluated for tolerance and survival capacity in presence of Cr (VI), Pb (II), Cd (II) and Ni (II) and the effect of exposure of these heavy metals on it.

**MATERIALS AND METHODS**

**Materials**

Commercially available probiotic \textit{Bacillus clausii} was procured from local chemist. It is marketed by Sanofi Synthelabo Pvt Ltd. Powai, Mumbai, India as a spore suspension under the name “Enterogermina®”. Potassium dichromate, lead nitrate, cadmium sulphate and nickel sulphate are the salts of heavy metals which have been selected for this study and were used as sources of Cr (VI), Pb (II), Cd (II) and Ni (II), respectively. Antibiotic discs were procured from HiMedia, India for kanamycin (30 µg), norfloxacin (10 µg), chloramphenicol (30 µg), amoxycillin (10 µg), ciprofloxacin (5 µg), and ampicillin (10 µg).

**Methods**

**Minimum Inhibitory Concentration (MIC)**

MIC of Cr (VI), Pb (II), Cd (II) and Ni (II) for \textit{B. clausii} was assessed by method of Mistry et al\textsuperscript{23} with some modifications. Spores were germinated in nutrient broth (NB) and inoculated on nutrient agar (NA) plates supplemented with two-fold concentration of respective heavy metals ranging from 1-512 ppm. These plates were incubated at 37°C for 24 hrs. The lowest concentration of the respective heavy metal which inhibited the growth of probiotic was considered as the MIC of that heavy metal for \textit{B. clausii}.

**Characterization of Heavy Metal Resistant \textit{B. clausii}**

Various characterization parameters of \textit{B. clausii} were evaluated before and after 24 hrs. exposure to Cr (VI), Pb (II), Cd (II) and Ni (II). This was done to assess whether the respective heavy metal exposure affects characteristics of the test organism.

**Morphological Characterization**

Observations on cell size, shape, colony characteristics and staining properties were performed on \textit{B. clausii} before and after exposure to test heavy metals.

**Biochemical Characterization**

**Catalase Test**

Unexposed and exposed cultures of \textit{B. clausii} for Cr (VI), Pb (II), Cd (II) and Ni (II) were cultured on NA slants. Few drops of \textit{H}_2\textit{O}_2 were added to the slant after 24 hrs. and observed for immediate bubbling\textsuperscript{24}.

**Methyl Red and Voges Proskauer (MRVP) Test**

MRVP test was performed to determine glucose fermentation products. MR test was done according to methodology of Clark and Lub\textsuperscript{25} while for VP test method of Voges and Proskauer\textsuperscript{26} modified by Barritt\textsuperscript{27} was followed. This was done on unexposed and exposed \textit{B. clausii} to Cr (VI), Pb (II), Cd (II) and Ni (II) respectively, in sets of glucose phosphate broth tubes. The tubes were inoculated and incubated for 72-96 hrs. Methyl red was added to one tube of the set to check development of acid. To the other tube, 12 drops of reagent VP-I was added followed by 2-3 drops of reagent VP-II. The tubes were exposed to air and were shaken intermittently. One tube remained uninoculated and acted as control.

**Sugar Fermentation Test**

Sugar fermentation test was performed according to procedure of Cappuccino and Sherman\textsuperscript{28}. A set of sugar fermentation tubes were
prepared with different sugars (lactose, sucrose, glucose, sorbitol and mannitol). Phenol red was added to the broth as pH indicator to check for acid production and Durham’s tube were placed in the broth to check for gas production. The broth was inoculated with unexposed and exposed *B. clausii* to each heavy metal respectively. An uninoculated tube was kept as control.

**Antibiotic Sensitivity Test**

To analyse whether Cr (VI), Pb (II), Cd (II) and Ni (II) exposure caused any change in antibiotic sensitivity of *B. clausii*, Kirby-Bauer disc diffusion method was performed using antibiotic discs. Zone of inhibition was measured after 24 hrs. for the unexposed and exposed cultures of *B. clausii*.

**Probiotic Characterization**

Efficacy of *B. clausii* as a probiotic was studied by acid and bile tolerance assays after exposure to heavy metals under study. For both assays, methodology of Hassanzadazar et al. was followed with some modifications.

For acid tolerance assay, *B. clausii* exposed to Cr (VI), Pb (II), Cd (II) and Ni (II) respectively, was added to different broths of pH 2, 3 and 4. Growth of exposed *B. clausii* was monitored by viable cell count that was performed by pour plate technique for every hour for 3 hrs. Prior to plating, ten- fold serial dilution of the inoculum was prepared in 0.1% peptone water. All the experiments were done in triplicates. Cell counting was done after 24 hrs. of incubation at 37°C.

For bile tolerance assay, NB with bile salt concentration of 0.2, 0.3 and 0.4% were prepared. B. clausii after 24 hrs. exposure to Cr (VI), Pb (II), Cd (II) and Ni (II) was added to the respective broths. Viable cell count was performed by pour plate technique. The inoculum was prepared hourly for 3 hrs. by ten- fold serial dilution in 0.1% peptone water. Colony count was done after 24 hrs. incubation at 37°C.

RESULTS AND DISCUSSION

Minimum Inhibitory Concentration (MIC)

In presence of nickel and chromium, B. clausii showed growth till 128 ppm and hence MIC was obtained as 256 ppm. In case of cadmium exposure, MIC was obtained at 64 ppm. However, after lead exposure, B. clausii showed good growth till 512 ppm and thus no MIC was recorded.

Earlier, environmental species of genus Bacillus have shown bioremediation of Cr (VI), Pb (II), Cd (II) and Ni (II). The genetic determinants for heavy metal tolerance might be borne either on plasmids, transposons or genomic DNA. In fact, these determinants are responsible for increased tolerance of microorganisms for heavy metals and are reported more in heavy metal polluted sites rather than in unpolluted sites.

The results of the assay for MIC indicate combined resistance of B. clausii and high MIC values for the heavy metals tested. The earlier studies conducted by Silver and Alam and Imran.
also have reported similar combined resistance of *B. clausii*. Further studies have reported that bacteria which are multi-heavy metal resistant have greater MIC values as compared to bacteria showing resistance to a single heavy metal. Further studies have reported that bacteria which are multi-heavy metal resistant have greater MIC values as compared to bacteria showing resistance to a single heavy metal. According to WHO, the guideline values for Cr (VI), Pb (II), Cd (II) and Ni (II) in drinking water are 0.05 mg/L, 0.01 mg/L, 0.003 mg/L and 0.07 mg/L, respectively. *B. clausii* has shown MIC values much above the permissible values of these heavy metals in drinking water, indicating that it has the potential for bioremediation of the above mentioned heavy metals.

**Morphological and Biochemical Characterization**

Vegetative cells of *B. clausii* exposed to heavy metal stress did not exhibit any change in their various morphological characteristics like cell shape, cell size, colony characters etc. Similar observations were made when heavy metal exposure did not affect the biochemical properties of the test organism. These results indicate that 24 hrs. exposure of *B. clausii* to Cr (VI), Pb (II), Cd (II) and Ni (II) could not modify or transform the organism’s basic characteristics as depicted in Table 1.

**Antibiotic Sensitivity Test**

An organism can be either tolerant or resistant to antibiotics. For an organism to be resistant, it must grow in constant presence of low concentration of antibiotic. If an organism is categorized as tolerant, it means that it can survive for short duration of high concentration of antibiotic. This helps to determine the
successful clinical use of antibiotics. In this study, upon exposure to heavy metal stress, a marked increase was observed in antibiotic sensitivity of *B. clausii* for the antibiotics used (Fig 1). Against amoxicillin, Pb (II) exposed *B. clausii* showed maximum change (from 9 mm to 33 mm) (Fig 2, Fig 4) while minimum change was recorded for Ni (II) (Fig 2, Fig 5) exposed and Cd (II) exposed culture (from 9 mm to 17 mm) (Fig 2, Fig 6b). Lead exposed culture recorded maximum (from 15 mm to 34 mm) (Fig 2, Fig 4) and cadmium exposed culture recorded minimum (from 15 mm to 21 mm) change against ciprofloxacin (Fig 2, Fig 6a). After exposure to lead, *B. clausii* showed doubling of antibiotic sensitivity (from 11 mm to 22 mm) against norfloxacin (Fig 2, Fig 4) while minimum was for chromium exposed culture (from 11 mm to 17 mm) (Fig 2, Fig 3). The zone of inhibition increased from 8 mm to 28 mm after lead exposure which was maximum for ampicillin (Fig 2, Fig 4) while minimum increase was for Cr (VI) (Fig 2, Fig 3) and Cd (II) (Fig 2, Fig 6c) exposed *B. clausii* (from 8 mm to 17 mm respectively). Pb (II) exposed test organism recorded maximum change against kanamycin (13 mm to 31 mm) (Fig 2, Fig 4) while Cd (II) exposed *B. clausii* showed negligible change (13 mm to 15 mm) (Fig 2, Fig 6b). For chloramphenicol, after exposure to nickel, *B.
B. clausii showed a tremendous increase in the zone of inhibition from 7 mm to 32 mm (Fig 2, Fig 5) while negligible change was found in Cd (II) exposed test probiotic (7 mm to 10 mm) (Fig 2, Fig 6a). This behaviour may be related to presence of proteins involved in chloramphenicol and kanamycin resistance have also been identified in proteome of B. clausii. Thus, lead exposure caused maximum change in antibiotic sensitivity while cadmium exposure led to minimum change. According to above definition, B. clausii can be considered as resistant to the antibiotics tested against and can therefore be used to replenish the microflora of the gut after antibiotic treatment, even after heavy metal exposure. The results of above assay indicate that the antibiotic resistance of B. clausii decreases upon exposure to Cr (VI), Pb (II), Cd (II) and Ni (II). Similar results obtained by Tuckfield and McArthur, Habi and Daba, and Belapurkar et al., which also support our findings. Various researchers have postulated multiple reasons for this observation. The reasons can be inactivation of enzymes and proteins by heavy metals involved in antibiotic resistance, irreversible inhibition of
ribosome function by heavy metals\textsuperscript{47} or chelation of antibiotics by heavy metals thus reducing their concentration\textsuperscript{48}.

From the above results, it can also been concluded that \textit{B. clausii} has potential to resist and tolerate both heavy metals and antibiotics. In bacteria, antibiotic resistance and heavy metal tolerance are genetically linked through R- plasmid\textsuperscript{49-51}. According to the study of Alam and Imran\textsuperscript{39} selective pressure of the heavy metals causes co-selection of antibiotic resistance, albeit indirectly.

**Probiotic Characterization**

As \textit{B. clausii} is a probiotic microorganism, it can survive low pH conditions of stomach as well as in presence of bile salts in the intestinal tract. To determine the effect of heavy metal stress on its probiotic efficacy of \textit{B. clausii}, acid and bile tolerance assays were performed.

**Acid Tolerance Assay**

When Cr (VI) exposed \textit{B. clausii} was inoculated in pH 2, 3 and 4 respectively and growth was monitored for 3 consecutive hours, it was observed that maximum CFU (colony forming units) was obtained in pH 4.

**Bile Tolerance Assay**

When Ni (II) exposed \textit{B. clausii} was inoculated in different bile concentrations (0.20\%, 0.30\%, and 0.40\%) and growth was monitored for 3 consecutive hours, it was observed that maximum CFU (colony forming units) was obtained in 0.20\% bile concentration.

**Fig. 13.** Bile tolerance of \textit{B. clausii} after exposure to cadmium

**Fig. 14.** Bile tolerance of \textit{B. clausii} after exposure to nickel
units) were obtained at pH 3 after 3 hrs. (Fig. 7). Similar result was obtained for Pb (II), Cd (II) and Ni (II) exposed B. clausii (Fig. 8-10). This is in corroboration with a study conducted by Sahadeva et al.\textsuperscript{52} which says that for an organism to be acid tolerant it must show maximum growth at pH 3 after 3 hrs.

Mechanisms of acid tolerance are more prominent in Gram positive bacteria like Bacillus spp. as they attain higher cell densities which enhance biofilm formation and communication amongst cells\textsuperscript{55}. These mechanisms are (i) change in types of fatty acids of cell membrane\textsuperscript{54} (ii) exchange of proton for an amino acid in presence of amino acid carboxylase\textsuperscript{55,56} (iii) conserving structures of macromolecules like proteins with the help of chaperones\textsuperscript{54,57,58} and (iv) counteracting the low pH with production of alkaline molecules like ammonia\textsuperscript{59}. Since the test organism belongs to genus Bacillus, it probably suggests use one or more of these mechanisms. Interestingly, despite high heavy metal stress, acid tolerance of B. clausii was not affected as concluded by the results of this assay.

**Bile Tolerance Assay**

For a probiotic to be categorized as bile tolerant, it must have maximal growth at 0.3% bile salt concentration after 3 hrs.\textsuperscript{60,61} When B. clausii exposed to heavy metals under study was inoculated in bile salt concentrations of 0.2%, 0.3% and 0.4%, highest CFUs were observed at 0.3% bile after 3 hrs. Hence, subjection of B. clausii to heavy metal stress did not change its bile tolerance property (Fig. 11-14).

In contrast to defined mechanisms of acid tolerance, the methods by which bacterial cell counters bile stress is not well defined. One of the mechanism is with the use of enzyme bile salt hydrolase\textsuperscript{62}. Apart from this, complex gene expression is also known to be responsible for bile tolerant property of bacteria\textsuperscript{63-66}.

It may be noted that even under heavy metal stress, B. clausii is able to retain its probiotic efficacy by probable use of different mechanisms and can be applicable for bioremediation of heavy metal, \textit{in vivo}.

**CONCLUSION**

Anthropogenic and natural activities are the causes of Cr (VI), Pb (II), Cd (II) and Ni (II) contamination of soil and water and air. These are toxic heavy metals which reach humans through the food chain and cause detrimental effects on their health. Chromium and lead are systemic toxicants while nickel and cadmium are carcinogens. When the effects of these heavy metals were tested on a probiotic microorganism, B. clausii, no change was observed in its morphological and biochemical properties and its probiotic efficacy. Hence, it can be concluded that B. clausii, a commercial probiotic has the potential for \textit{in vivo} bioremediation of Cr (VI), Pb (II), Cd (II) and Ni (II) and can therefore benefit the society at large by reducing the toxicity of these heavy metals in the human gut.

**ACKNOWLEDGEMENTS**

The authors wish to thank Ar. Achal Choudhary, President and Dr. Sanjay Nagar, Head, Department of Biotechnology, IPS Academy, Indore for their valuable assistance regarding infrastructural and laboratory facilities.
