Abstract  To determine the prevalence and etiology of Asymptomatic bacteriuria (ASB) and antimicrobial resistance of urinary isolates among diabetics mellitus and non-diabetics, a total of 200 patients comprising of 120 diabetes mellitus (DM) and 80 non-diabetes were studied. ASB was detected in 36% patients of which 40% are diabetic and 30% are non-diabetic. Coagulase Negative Staphylococcus (CoNS) were the predominant organism (36.36%) isolated from the urine of both diabetic and non-diabetic. We observed occurrence of ASB significantly increases with age in DM patients and is more prevalent in DM females compared to non-DM females. Whereas Klebsiella sp., Candida sp., and E. coli were also significantly more prominent in DM patients. Most isolates of Klebsiella sp. and E. coli showed resistances to multiple antibiotics tested. For the uropathogens found in the samples tested Levofloxacin proved to be the most sensitive antibiotic. The study revealed a high prevalence of ASB among DM than non-DM subjects. This study also demonstrates multiple drug resistance observed in both DM and non-DM subjects, therefore irrational and indiscriminate use of antibiotic should be avoided.

Keywords  Asymptomatic Bacteriuria, Diabetes Mellitus, Drug Resistance, Antibiotic

1. Introduction

Diabetes is one of the common metabolic disorders, influenced by genetic, ethnic and socioeconomic factors. World health organization (WHO) has reported that prevalence of diabetes is increasing in developing counties such as India. Diabetes mellitus (DM) patients have been reported to be more predisposed to urinary tract infections (UTI) [1]. The mechanism of pathogenesis for this association is not fully elucidated however it is suggested that high glucose concentration in urine may favour the growth of pathogenic micro-organism and stimulate UTI [2]. UTI is characterized by bacteriuria which results in both symptomatic and asymptomatic infection. Asymptomatic UTIs are more prevalent in women. Asymptomatic bacteriuria (ASB) is a form of UTI characterized by the presence of significant amount $>10^5$ cfu/ml of bacteria in urine [3, 4]. Several studies have demonstrated the association of ASB with diabetes, and it is also reported that the prevalence is higher in people with diabetes than non-diabetes [5-7]. ASB is common among human population and may lead to serious complications if not properly managed. ASB has been identified as a risk factor for acquiring symptomatic UTI especially in diabetic women. UTI are more severe in diabetic patients involving life-threatening complications such as emphysematous Pyelonephritis, and Renal papillary necrosis [9].

The most frequently isolated ASB in urine includes Escherichia coli, Klebsiella pneumoniae, CoNS, Streptococcus pyogenes, Streptococcus agalactiae, and Enterococcus fecalis [3-5]. E. coli is known most common uropathogens; other micro-organisms are prevailing. Antibiotic resistance of uropathogens is increasing due to emerging of multiple drug resistant strains [3, 5, 10]. Levofloxacin has been reported to be effective against most of the urinary isolates [4, 10]. Currently, there is lack of systematic study in Patna region that describe profile of ASB among DM Patients and non-DM patients. This paper describes the current trends of ASB between DM patients and non-DM patients and their antibiotic resistance properties.

2. Material and Methods

A total of 200 patients (120 diabetics and 80 non diabetics) were included in the study, consent was obtained from the patients before sampling. All these patients belong to Patna district, Bihar, India. Urine samples were collected into
sterile container after proper washing of genitalia to avoid contamination. Samples were placed in refrigerator (4°C) and further analysed within 8 hours. In case if immediate delivery of the urine sample to the laboratory was not possible, Boric acid (1% w/v) was used as a preservative.

Urine was examined to detect blood, pus, epithelial cell, cast, protein, sugar and any other cells. A calibrated 10µl loop was used to inoculate un-centrifuged urine into Nutrient Agar, MacConkey’s Agar, Blood Agar, and Sabouraud’s Dextrose Agar and incubated at 37°C overnight (about 12-16 hrs). Isolates were identified using standard biochemical techniques. Drug sensitivity test (DST) was carried out by Kirby – Bauer Disc diffusion methods using standard procedures [16].

Antibiotic used in the study were Nalidixic acid, Penicillin, Augmentin Ceftriaxone, Cefuroxime, Ciprofloxacin, Levofloxacin, Gentamicin, Co-trimoxazole, Azithromycin, and Doxycycline. Antibiotics were obtained from Hi Media Laboratories, Mumbai, India.

The statistical analysis of the results was carried out using Chi-square test. P-values <0.05 were considered statistically significant.

3. Result

Asymptomatic Bacteriuria (ASB) is more prominent in DM female

To examine the prevalence of ASB in Patna district, 200 patients of different age group of Patna region were tested for ASB in their urine. The distribution of ASB in diabetic and non-diabetic patients according to gender and age is shown in Table 1. There was significant increase in prevalence of ASB with age (p<0.05) (Table 1). The prevalence of ASB was significantly higher in DM patients in comparison to non DM patients (Table 1). To investigate the relationship between gender, diabetes and ASB; we compared percentage of ASB in male versus female participants and diabetic versus non diabetic. We found that male participants have less percentage of ASB as compared to female participants (p<0.001). There is no significant difference of ASB between male participants of DM and non DM patients (p=0.31). There is significant increase of ASB in female subjects regardless of DM and non DM (Table 1). We observed that DM (female/male) subjects show more prevalence of ASB compared to non DM female/male (p=0.005). However, altogether these results suggest that diabetic females had highest prevalence of ASB based on the population studied.

P- Values on the table are between diabetic and non-diabetics. NS, S stands for not significant and significant respectively. N stands for total number of patients. The presence of Asymptomatic Bacteriuria (ASB) in diabetes mellitus female is significantly more in comparison of diabetes mellitus male.

Coagulase negative staphylococci (CoNS) is the most prevalent organism in the urine

To investigate the occurrence of different bacterial species found in urine of DM and non-DM patients. We tested the presence of bacterial species in urine and analyzed the percentage occurrence. We found the coagulase negative staphylococci were the most prevalent organisms in urine of DM and non-DM patients. The Klebsiella sp. and Proteus sp. were significantly more in non-DM compared to DM (p<0.001). Candida sp, Serratia and Streptococcus sp were found frequently in DM patients. The other species such as E. coli and Staphylococcus aureus were found in both DM and non-DM patients. The Proteus sp and Enterobactor were rarely found in urine of DM and non-DM patients (Table 2). All together, it shows that there is wide spectrum of different bacterial species in both diabetics and non-diabetics. However, CoNS is the most prevalent organism in urine of both DM and non-DM patients.

P values on the table are between diabetic and non-diabetics. NS, S stands for not significant and significant respectively. N stands for total number of patients. The Proteus sp and Enterobactor were rarely found in urine of DM and non-DM patients. CoNS is the most prevalent organism in urine of both DM and non-DM patients.

Table 1. Distribution of Asymptomatic bacteriuria with respect to Age and Sex

| Age (in yrs) | Diabetics with ASB (%) | Non-diabetics with ASB (%) | Total with ASB (%) | Number of patients |
|--------------|------------------------|----------------------------|--------------------|-------------------|
| 16-30        | 3 (25)                 | 2 (16.67)                  | 5 (41.67)          | 12                |
| 31-40        | 3 (16.67)              | 2 (11.12)                  | 5 (27.78)          | 18                |
| 41-50        | 10 (20)                | 5 (10)                     | 15 (30)            | 50                |
| >50          | 32 (26.67)             | 15 (12.5)                  | 47 (39.17)         | 120               |
| P = 0.783, NS| P = 0.574, NS          | P = 0.659, NS              |                    |                   |
| Sex          |                        |                            |                    |                   |
| Male         | 6 (8.57)               | 4 (5.71)                   | 10 (14.28)         | 70                |
| Female       | 42 (32.30)             | 20 (15.38)                 | 62 (47.69)         | 130               |
| P < 0.001, S | P = 0.002, S           | P < 0.001, S               |                    |                   |
| Overall prevalence | 48/120 (40%) | 24/80 (30%) | 72200 (36%) | 200 |
Levofloxacin is the most effective antibiotic against *E. coli* and *Klebsiella sp*.

We tested efficacy of different antibiotics (Penicillin, Nalidixic acid, Augmentin, Ceftriaxone, Cefuroxime, Ciprofloxacin, Levofloxacin, Gentamicin, Co-trimoxazole, Azithromycin Doxycycline) against bacterial species by testing using *E. coli* and *Klebsiella sp* isolated from urine of DM and non-DM patients. The prevalence of *E. coli* has no significant difference in DM and non DM patients (p=0.24); while *Klebsiella sp* was found to be more frequently associated with diabetic patients (Table 2). We observed that *Klebsiella sp* isolated from DM patients were resistant against Cefuroxime and Ciprofloxacin; while both these antibiotics were effective in inhibiting growth of *E. coli* isolated either from DM and non-DM patients (Table 3). Antibiotics such as Gentamicin and Co-trimoxazole did not effectively inhibit growth of *E. coli* isolated both from DM and non-DM patients (Table 2). All together, our current study show Levofloxacin is potent antibiotic against *E.coli* and *Klebsiella sp*; while other antibiotic such as penicillin, Nalidixic, Gentamicin, Co-trimoxazole are show resistance against *E.coli* and *Klebsiella sp*.

### 4. Discussion

Asymptomatic bacteriuria is a major concern for diabetes mellitus patients. No significant information was available on the occurrence of ASB amongst diabetics versus non diabetics, and effect of factors like age and gender on the occurrence of ASB in Patna district. Therefore, the present study was aimed to determine the prevalence and spectrum of microorganisms responsible for asymptomatic bacteriuria in DM versus non-DM. The study also aimed to determine antimicrobial resistance of urinary isolates in DM and non-DM subjects.

The present study revealed an overall prevalence of ASB in DM compared to non-DM subjects. Our result are in consensus with that of the earlier reports which reported prevalence of ASB in diabetes (36.2%) compared to non-diabetes (18.5%) [5]. In Cameroon, high prevalence
(35.2 – 58.3%) of bacteriuria has been reported [14, 17]. On the contrary, the prevalence of ASB in this study is higher than that of some studies which recorded 5.3 – 26% in diabetics and 3.5 – 15% in non-diabetics [3, 4, 18, 19, 20]. Consequently, the issue of prevalence of ASB remains debatable. This inconsistency has been attributed due to variations in sample size, geographical location, culture or screening method [11]. Our studies also show ASB was significantly higher in DM and non-DM patient. This is in line with majority of previous reports [7, 12].

As per our study, the prevalent microorganisms found in ASB in Patna region were *coagulase negative Staphylococcus* (36.36%), *Klebsiella sp.* (15.9%), *Candida sp.* (14.78%), *E. coli.* (18.18%) and *Serratia sp.* (5.68%) each. As per our study the most prevalent microorganisms found in ASB was *coagulase negative Staphylococcus* (36.36%), whereas most of the studies in other regions report *E. coli* to be the most predominant [5-9]. The predominance of bacteria other than *E. coli* in the urinary tract has been reported by some of the studies. Recent studies in Nigeria show that *Staphylococcus aureus* was the most common bacteria in urine of DM and non-DM patient [12]. The *Staphylococcus sp.* is found as a normal skin flora. The high prevalence of *Staphylococcus sp.* of ASB may be due inclosed inside of urinary tract during sexual intercourse [12]. The high prevalence of CoNS might be due to inappropriate use of antibiotics which may encourage the proliferation of highly resistant bacteria such as CoNS [21]. The frequency of isolation of uropathogens was similar among DM and non-DM except for *Candida sp.* and *Serratia sp.* that were more frequent in DM patients. On the contrary, *Klebsiella sp.* was isolated more from non-DM. The precise reason why there is difference in ASB of diabetics and non-diabetics is not well understood. One of the simple reason proposed that excess glucose promotes the growth of some bacterial species such as *Candida sp.* [22].

Results of the antibiotic susceptibility test of DM and non-DM patients show that there was significant difference in the resistant pattern of Cefuroxime and Ciprofloxacin. The rate and spectrum of antibiotic resistance in this study is similar to that of studies conducted in other developing countries [3, 4]. High resistance to Co-trimoxazole and Nalidixic acid may be due its frequent use in Patna district to treat urinary tract infections and other infectious diseases. In the present study, we found *E. coli* strains demonstrated multi-drug resistance especially to Gentamicin, Nalidixic acid, Doxycycline, Cefuroxime and erythromycin. Multi-drug resistance of *E. coli* is a common phenomenon as reported by other authors [5, 10, 18]. The most resistant Gram positive organisms were CoNS. These bacteria have been reported to show high resistance to multiple antibiotics [21]. The 15% resistance of CoNS to Gentamicin and a corresponding 22.5% resistance to Vancomycin observed in this study could be an indication of the circulation of Gentamicin–Vancomycin resistant strains in the community. Infections with these strains are very difficult to treat and the consequences could be fatal.

### 5. Conclusions

The major findings of this study were Asymptomatic Bacteriuria is more prominent in DM female patients. Coagulate negative staphylococcus is most prevalent organism in urine sample in Patna region. Levofoxacin was found to be the most effective antibiotic against *E. coli* and *Klebsiella sp.* of ASB, in Patna region. In general, there is no significant difference in the resistance pattern between DM and non-DM patients. These studies strengthen earlier observation that shows the antibiotic resistance distribution of ASB in Patna region, India.
