Abstract  We show how it is possible to rewrite the BFKL equation for the unintegrated gluon distribution, in terms of integrated gluons, similar to that used in DGLAP. We add to our equation the next-to-leading log terms which provide exact energy-momentum conservation and account for the kinematic constraint in real gluon emission. In this way the equation includes the major part of the higher-order corrections to BFKL evolution. We discuss the possibility to obtain a unified BFKL–DGLAP evolution equation relevant to processes at the LHC where both log(1/x) and log Q² are large simultaneously.

1 Introduction

Originally the BFKL equation [1–4] was proposed to describe the high-energy behaviour of processes involving hadrons, such as proton–proton scattering or deep inelastic lepton–proton scattering. The BFKL equation for the amplitude of such processes sums up all the higher-order α₃ corrections where the small value of QCD coupling α₃ is compensated by the large logarithm of the energy, √s; that is the amplitude has the form

\[ A(x) = \sum_n C_n(\alpha_3 \ln x)^n. \]  

(1)

Recalling that x ∼ Q²/s, where Q² is the hard scale of the process, it follows that the BFKL equation may be regarded as an equation for the ln(1/x) evolution of unintegrated gluon density of the proton, f(x, k_t), which depends on two arguments: the proton momentum fraction x carried by a gluon and its transverse momentum, k_t. A feature of this evolution is diffusion of the gluon density in lnk_t space.

On the other hand, DGLAP evolution, which sums the α₃ln Q² terms, has contributions which are strongly ordered in k_t, and is written in terms of integrated parton densities which no longer depend on k_t. The domains in the (x, Q²) plot, where pure BFKL and pure DGLAP evolution are appropriate, are quite distinct. In practice, however, we really should sum up both the BFKL and the DGLAP logarithms. In particular, at the LHC energy of √s = 14 TeV the most interesting kinematical domain corresponds to the scale Q² ∼ M_W² ∼ 6400 GeV² (that is ln(Q²/M_W²) ∼ 8) and x ∼ M_W/√s ∼ 0.005 (that is ln(1/x) ∼ 5). It is a region where both the BFKL and the DGLAP logarithms are important.

In order to be able to compare the BFKL and DGLAP evolutions it would be valuable to express the BFKL equation in terms of an integrated gluon distribution, as conventionally used in the DGLAP approach. Moreover, this would open the way to formulate an expression which accounts for both the DGLAP and the BFKL logarithms in terms of integrated densities.¹

In this form, it would be easier to study the BFKL effects, caused by contributions which violate the strong-k_t ordering or by higher-twist contributions (both of which are present in BFKL, but are absent in DGLAP evolution), and/or to perform a BFKL-based global analysis analogous to the traditional global parton analyses made within the DGLAP approach.

Recall that the BFKL equation describes evolution in the ln(1/x) direction starting from some input (which depends on Q²) at fixed x = x_0, while DGLAP generates ln Q² evolution starting from input at fixed Q² = Q₀². The power of the x-dependence in DGLAP evolution is driven mainly by the input distribution. On the other hand, in the BFKL approach

¹ Such a unified BFKL–DGLAP equation was proposed in [5], but in terms of the unintegrated parton densities. Note that it is not the same as the resummation of the large, enhanced by ln(1/x), BFKL contributions to the DGLAP splitting functions, that is, to the anomalous dimensions, as was done in [6]. Recall that, besides the leading twist, the BFKL equation includes higher-twist effects which account for gluon reggeisation.
the small \(x\) behaviour is completely determined by the BFKL equation.

To discover such a BFKL equation for an ‘integrated’ gluon density is the purpose of this paper.\(^2\) Can this be done, so that the low \(x\) dependence of the integrated gluon PDF is completely generated within the BFKL framework? It will clearly involve higher-twist effects coming from the reggeisation of the gluon, and hence lie outside a pure DGLAP framework (which is based on leading twist only). However, if it can be done, then it will open the way to obtaining a DGLAP-like evolution for an integrated gluon PDF in terms of a single evolution variable which sums both the BFKL \(\log(1/x)\) and DGLAP \(\log Q^2\) contributions. We comment further on this attractive possibility in Sect. 5.

Note that, by summing up all the \(\ln(1/x)\)-enhanced contributions, the BFKL equation deals with kinematics where the fraction, \(z\), of the parent gluon momentum carried by the following gluon is small; \(z \ll 1\). In this situation one may neglect the momenta of the new gluons in comparison with the momentum of parent gluon. However, in reality, the typical values of \(z\) are not so small. Therefore the parton distribution, generated by BFKL evolution, violates the energy-momentum conservation law. Formally this violation is a next-to-leading Log (NLL) effect, but numerically it may be important. Moreover, since the majority of available data comes from Deep Inelastic Scattering where the incoming photon does not interact with the gluon directly, in the global parton analyses the normalisation of gluon distribution is mainly fixed by the energy conservation sum rule. Therefore it is crucial to have an equation which automatically satisfies the energy-momentum conservation law. For this reason, in the equation for integrated gluon density that we propose, we include the NLL term which restores energy-momentum conservation.

Besides this, we will take care of the kinematical cutoff \(k_T^2 < k_T^2/z\)\(^8\) for real gluon emission. Again, formally, since \(z \ll 1\), the integral over the intermediate momentum \(k_T^2\) may run up to \(k_T^2 \rightarrow \infty\). However, in spite of the fact that this integral is well convergent at \(k_T^2 \gg k_T^2\), for too large \(k_T^2 > k_T^2/z\) the contribution of the longitudinal component to the virtuality \(k_T^2\) becomes so large that it kills the leading logarithmic form of \(dz/z\) integration, providing, in this way, an effective cutoff \(k_T^2 < k_T^2/z\).

The inclusion of this cutoff (sometimes called the ‘consistency constraint’) explicitly in the BFKL equation was found to play a crucial role; it accounts for a major part of the NLL and higher-order corrections. Let us explain the importance of this statement. The BFKL resummation of the \(\ln(1/x)\) contributions shown in Eq. (1) is at Leading Log (LL) level. It results in a gluon density which behaves as \(f \propto x^{-\omega}\) as \(x \rightarrow 0\), where \(\omega_0 = \bar{\alpha}_s 4 \ln 2\), with \(\bar{\alpha}_s \equiv 3\alpha_s/\pi\). Resumming the next-to-leading logs \([11]\) gives a behaviour of the form \(f \propto x^{-\omega}\) where now

\[
\omega = \omega_0(1 - 6.5\bar{\alpha}_s). \tag{2}
\]

At first it was thought that such a large NLL correction would mean that no stable small \(x\) predictions could be made using the BFKL procedure. Next, the value of the NLL correction depends on the choice of renormalisation scheme. Recently, it was shown, however, \([12]\) that applying the principle of maximum conformality and using the more physical MOM-scheme a much more stable value of \(\omega\) can be obtained. Moreover, it is possible to identify higher-order terms and then to resum them. Indeed Ciafaloni et al. \([13,14]\) carried out an all-order \(\ln(1/x)\) resummation of the following effects: (i) running \(\alpha_s\), (ii) the non-singular DGLAP terms and (iii) the angular ordering and energy constraints. The result was a stable \(x^{-\omega}\) behaviour, which is consistent with observations.

In fact, prior to this, the fit in \([5]\), which was based on a unified BFKL/DGLAP equation for the unintegrated gluon, incorporates these all-order \(\ln(1/x)\) contributions, where the imposition of the kinematic (or so-called consistency) constraint \([9]\) plays a major role.

In Sect. 2 we recall the original BFKL equation for the \textit{unintegrated} gluon density, and express it in a form already including the kinematical cutoff, \(k_T^2 < k_T^2/z\). Also, here, we add the next-to-leading term which restores energy-momentum conservation. Then, in Sect. 3, we introduce the \textit{integrated} gluon distribution \(F(x, q)\) and obtain the equation for \(F\). The final expression is given in Sect. 4, and an overview presented in Sect. 5.

\section{2 BFKL equation for unintegrated gluons}

Recall that the BFKL equation can be written as an integral equation for the unintegrated gluon distribution \(f(x, k_T)\) (as conventionally used in BFKL evolution) in the form:

\[
f(x, k_T) = f_0(x, k_T) + \frac{\alpha_s}{2\pi} \int_x^1 \frac{dz}{z} \int_{k_T^2}^\infty \frac{d^2k_T'}{\pi} \times \mathcal{K}(k_T, k_T', z) f(x/z, k_T'), \tag{3}
\]

where the kernel is evaluated as

\[
\mathcal{K}(k_T, k_T', z) f(x/z, k_T') = 2N_c \frac{k_T^2}{k_T'^2} \times \left[ \Theta(k_T^2 - k_T'^2) f(x/z, k_T') - f(x/z, k_T) + \frac{f(x/z, k_T)}{\sqrt{4k_T'^2 + k_T^2}} \right]. \tag{4}
\]
The first term with the $\Theta$ function in the kernel\(^3\) can be understood as the effect of the emission of a daughter gluon with momentum $(x, k_t)$ from a parent gluon with momentum $(x' = x/z, k_t')$. The remaining terms (with $f(x/z, k_t)$) account for the loop correction originated by the trajectory of $t$-channel reggeized gluons. Note that now the BFKL kernel $K$ contains a third argument $z$ since here we have implemented the important kinematic constraint for real emission [5,8–10]

$$k_t'^2 < \frac{k_t^2}{z}, \quad (5)$$

to guarantee that only the leading logarithm part of the higher-order corrections is actually taken into account.

To ensure energy conservation, we subtract the term

$$\frac{\alpha_s}{2\pi} \int_0^1 dz \int_k^z \varphi(z) f(x, k_t')$$

from the right-hand side of Eq. (3). We can check that this conserves momentum by integrating both Eq. (3) and Eq. (6) with respect to $x$, and using the ‘integral’ identity

$$\int_0^1 dx \int_x^1 \frac{dz}{z} = \int_0^1 \frac{dz}{z} \int_0^z dx = \int_0^1 dx \int_0^1 \frac{z}{x} d\left(\frac{x}{z}\right) \quad (7)$$

Such a prescription is analogous to the $1/\omega \to 1/\omega - 1$ replacement proposed in [15] to achieve the same goal in $\omega$-representation. Note that the integral over $z$ in Eq. (6) does not have a logarithmic $(dz/z)$ form, whereas in Eq. (3) the form $(dz/z)$ generates the factor $1/\omega$ in $\omega$ representation. Recall that $f(x, k_t) \propto x^{-\omega}$.

3 BFKL equation for integrated gluons

In this section we show how the BFKL equation can be rewritten in terms of the integrated gluon distribution given by

$$F(x, q) = \int_{k_0^2}^{q^2} \frac{dk_t^2}{k_t^2} f(x, k_t) = \int_{k_0^2}^{q^2} d\ln k_t^2 f(x, k_t). \quad (8)$$

First, we integrate Eq. (3) over $dk_t^2/k_t^2$ from $k_0^2$ to $q^2$, and express it in the form

$$F(x, q) - F(x, k_0) = F_0(x, q) - F_0(x, k_0) + \frac{N_c\alpha_s}{\pi} \left[ \int_x^1 \frac{dz}{z} (F_A + F_B + F_C) \right], \quad (9)$$

where $F_A$, $F_B$ and $F_C$ arise from the three terms in [...] of Eq. (4), but now integrated over both $k_t$ and $k_t'$; and where

$$F_0(x, q) = \int_{k_0^2}^{q^2} \frac{dk_t^2}{k_t^2} f_0(x, k_t). \quad (10)$$

We first consider $F_C$, which is given by

$$F_C = \int_{k_0^2}^{q^2} \frac{dk_t^2}{k_t^2} \int_{k_t^2/2}^{\infty} \frac{dk_t'^2}{k_t'^2} \left[ f(x', k_t') \right] \quad (11)$$

$$= \int_{k_0^2}^{q^2} \frac{dk_t^2}{k_t^2} \ln \left( \frac{\sqrt{4k_0^4 + k_t^4} + k_t^2}{2k_0^2} \right) f(x', k_t') \quad (12)$$

We have carried out one of the integrations, but so far our goal of having only an integrated distribution has not been achieved. To do so, we perform an ‘integration by parts’ using the identity

$$\int udv = \int d(uv) - \int vdu. \quad (13)$$

Note that on the right-hand side we only have an integrated $u$, whereas on the left-hand side we have an unintegrated $dv$. That is exactly what we need. In particular, to evaluate Eq. (12) we use

$$u \equiv \ln \left( \frac{\sqrt{4k_0^4 + k_t^4} + k_t^2}{2k_0^2} \right) \quad \text{and} \quad dv \equiv \frac{dk_t^2}{k_t^2} f(x', k_t) \quad (14)$$

and integrate by parts. We obtain

$$F_C = \left[ \ln \left( \frac{\sqrt{4k_0^4 + k_t^4} + k_t^2}{2k_0^2} \right) F(x', k_t') \right]_{k_t^2 = q^2} - \int_{k_0^2}^{q^2} \frac{dk_t^2}{k_t^2} \frac{f(x', k_t)}{\sqrt{4k_0^4 + k_t^4}}$$

$$= \ln \left( \frac{\sqrt{4k_0^4 + q^4} + q^2}{2k_0^2} \right) F(x', q)$$

$$- \ln \left( \frac{\sqrt{5} + 1}{2} \right) F(x', k_0) - \int_{k_0^2}^{q^2} \frac{dk_t^2}{k_t^2} \frac{f(x', k_t)}{\sqrt{4k_0^4 + k_t^4}} \quad (15)$$

Now, at least the $F_C$ term depends only on the integrated distribution $F(x, k_t)$ that satisfies

$$\frac{\partial}{\partial \ln k_t^2} F(x, k_t) = k_t^2 \frac{\partial}{\partial k_t^2} F(x, k_t) = f(x, k_t). \quad (16)$$

Next, we proceed to study the second term, $F_B$ in Eq. (9), where

$$F_B = -\int_{k_0^2}^{q^2} \frac{dk_t^2}{k_t^2} \int_{k_t^2/2}^{\infty} \frac{dk_t'^2}{k_t'^2} f(x', k_t') \quad (17)$$

$$= \ln(1 - z) \int_{k_0^2}^{q^2} \frac{dk_t^2}{k_t^2} f(x', k_t) \quad (18)$$

$$= \ln(1 - z) \left[ F(x', q) - F(x', k_0) \right]. \quad (19)$$
Here we have a singularity when $z \to 1$. This singularity will be removed when we include the momentum conservation term in Eq. (6). It will result in an expression like

$$\int \frac{dz}{z} \ln(1-z) \left[ F(x/z, q) - z F(x, q) \right],$$  
(20)

where now the integrand is non-singular at $z \to 1$.

The final contribution, the first term $F_A$ in Eq. (9), is the most dangerous term of the BFKL kernel. It is given by

$$F_A = \int q^2 \, d\mathbf{k}_1^2 \int_{k_1^2}^{k_2^2/z} \int_{k_1^2}^{k_2^2} \frac{d\mathbf{k}_i^2}{k_i^2} \left[ f(x', k_i') - f(x', k_i) \right].$$  
(21)

The integral over $k_i'$ of the first term in the above numerator, containing $f(x', k_i')$, can be evaluated by parts using the identity $udv = d(uv) - vdu$. In order to see explicitly the cancellation of the singularity at $k_i' = k_i$, we subtract $F(x, k_i)$ — a constant independent of $k_i'$ — from the integrated function. That is, we take

$$v(x, k_i') = F(x, k_i') - F(x, k_i),$$  
(22)

and integrate the first term in the numerator by parts. Omitting, for the moment, the second variable $x$, for clarity, we obtain

$$F_A = \int q^2 \, d\mathbf{k}_1^2 \left[ F(k_i') - F(k_i) \right] \biggr|_{k_i^2}^{k_i^2/z} + \int q^2 \, d\mathbf{k}_1^2 \left[ \frac{d}{d(k_i')^2} \frac{F(k_i') - F(k_i)}{(k_i')^2 - k_i^2} \right] \biggr|_{k_i^2}^{k_i^2/z} + \cdots$$  
(23)

Here the first term is well defined when $k_i^2 = k_i^2$. The second one should be as well, as long as we start with a well defined term in Eq. (21), as is the case. However, we cannot use the linearity property of integration to split the integrand into separate integrals. Instead, we use the Taylor series:

$$F(k_i') - F(k_i) = f(k_i) \frac{(k_i'^2 - k_i^2)}{k_i^2} + \left[ \frac{\partial}{\partial k_i^2} f(k_1) \right] (k_i'^2 - k_i^2)^2 + \cdots$$  
(24)

to check that the integration is well behaved. Nevertheless, we still have the unintegrated function $f(k_i)$ in the last term of Eq. (23). However, this contribution will disappear after we integrate over $k_i^2$ to obtain finally the integrated distribution. First, we must change the order of integration. We use

$$\int_{k_1^2}^{k_2^2} \, d\mathbf{k}_1^2 \int_{k_1^2}^{k_2^2} \, d\mathbf{k}_1^2 = \int_{k_1^2}^{k_2^2} \, d\mathbf{k}_1^2 \int_{k_1^2}^{k_2^2} \, d\mathbf{k}_1^2$$  
(25)

and again integrate by parts, this time for $f(k_i)$. We obtain

$$\int \frac{1}{|k_i^2 - k_i^2|} \left[ k_i^2 F(k_i') - F(k_i) \right]$$

$$- k_i^2 F(k_i) - F(k_i')$$

$$+ \int \frac{1}{|k_i^2 - k_i^2|} \left[ k_i^2 F(k_i') - F(k_i) \right]$$

$$- k_i^2 F(k_i) - F(k_i')$$

(26)

The above integrand can be simplified. The result is

$$F_A = \int q^2 \, d\mathbf{k}_1^2 \left[ F(x', k_i') - F(x', k_i) \right] \biggr|_{k_i^2 = k_i^2}^{k_i^2/z} + \int q^2 \, d\mathbf{k}_1^2 \left[ \frac{q^2}{k_i^2} F(x', k_i') - F(x', k_i) \right] \biggr|_{k_i^2 = k_i^2}^{k_i^2 = q^2}.$$  
(27)

To simplify further we apply the limits

$$F_A = \int q^2 \, d\mathbf{k}_1^2 \left[ \frac{F(k_i / \sqrt{z}) - F(k_i)}{|k_i^2 / z - k_i^2|} - \frac{F(k_0) - F(k_i)}{|k_0^2 - k_i^2|} \right]$$

$$+ \int q^2 \, d\mathbf{k}_1^2 \left[ \frac{q^2}{k_i^2} \frac{F(k_i) - F(q)}{|k_i^2 - q^2|} - \frac{F(k_i) - F(\sqrt{k_i^2})}{|k_i^2 - k_i^2|} \right].$$  
(28)

and regroup terms

$$F_A = \int q^2 \, d\mathbf{k}_1^2 \frac{k_i^2}{|k_i^2 - k_0^2|} + \int q^2 \, d\mathbf{k}_1^2 \frac{q^2}{k_i^2} \frac{F(k_i) - F(q)}{|k_i^2 - q^2|}$$

$$- \int q^2 \, d\mathbf{k}_1^2 \frac{k_i^2}{|1/z - 1|}.$$  
(29)

The contribution arising from momentum conservation can be rewritten in terms of the integrated gluons $F$ in analogous way.

4 The final result

We gather together the results (29), (19) and (15) for $F_A$, $F_B$ and $F_C$, and then insert them into Eq. (9). The result for the BFKL evolution in terms of the integrated gluon density, Eq. (8), is given by
\[ F(x, q) = F(x, k_0) + F_0(x, q) - F_0(x, k_0) \]
\[ + \frac{N_c \alpha_s(q^2)}{\pi} \int_x^{1} \frac{dz}{z} \int_{k_0^2}^{q^2} \frac{d^2 q}{k_t^2} \frac{2 F(x', k_t) - F(x', k_t')}{|k_t^2 - k_0^2|} \]
\[ + \int_{k_0^2}^{q^2} \frac{d^2 q}{k_t^2} \frac{q^2}{k_t^2} \frac{2 F(x', k_t) - F(x', q)}{|k_t^2 - q^2|} \]
\[ - \int_{k_0^2}^{q^2} \frac{d^2 q}{k_t^2} \frac{q^2}{k_t^2} \frac{2 F(x', k_t) - F(x', q)}{|k_t^2 - q^2|} \]
\[ + \ln(1 - z) [F(x', q) - F(x', k_0)] \]
\[ + \ln \left( \frac{\sqrt{q^2} + q^2}{2k_0^2} \right) F(x', q) \]
\[ - \ln \left( \frac{\sqrt{q^2} + 1}{2} \right) F(x', k_0) - \int_{k_0^2}^{q^2} \frac{d^2 q}{k_t^2} \frac{2 F(x', k_t) - F(x', q)}{\sqrt{4k_0^4 + k_t^4}} \]

energy–momentum conservation term. \( (30) \)

To obtain the energy-momentum conservation term we replace \( x' = x/z \) with \( x \) in first argument of the distributions \( F(x, k_t) \). We use the natural renormalisation scale for the QCD coupling \( \alpha_s(q^2) \); see e.g. [13, 14].

The expression \( (30) \) may be further simplified if we assume that perturbative QCD evolution can be extrapolated down to \( k_0 = 0 \) and \( F(x, k_0) \) vanishes at \( k_0 \to 0 \). Then for very small \( k_0 \)

\[ F(x, q) = F_0(x, q) + \frac{N_c \alpha_s(q^2)}{\pi} \int_x^{1} \frac{dz}{z} \]
\[ \times \left\{ \int_{k_0^2}^{q^2} \frac{d^2 q}{k_t^2} \frac{2 F(x', k_t) - F(x', q)}{|k_t^2 - q^2|} \right\} \]
\[ + \ln(1 - z) [F(x', q)] \]
\[ + \ln \left( \frac{q^2}{k_0^2} \right) F(x', q) \]

energy–momentum conservation term. \( (31) \)

We note the apparent \( k_0 \to 0 \) divergences in the integral, and in \( \ln k_0 \) occurring just before the ‘energy-momentum conservation term’. We may join the two divergences together to demonstrate their cancellation. In this way we obtain the relatively simple equation

\[ F(x, q) = F_0(x, q) + \frac{N_c \alpha_s(q^2)}{\pi} \int_x^{1} \frac{dz}{z} \]
\[ \times \left\{ \int_0^{q^2} \frac{d^2 q}{k_t^2} \frac{q^2}{k_t^2} F(x', k_t) - \frac{(q^2 - k_t^2)^2 F(x', q)}{|k_t^2 - q^2|} \right\} \]
\[ + \ln[z(1 - z)] F(x', q) \]

energy–momentum conservation term \( (32) \)

Thus we have a BFKL equation for the integrated gluon distribution, \( F \), which sums up all the leading \((\alpha_s \ln Q^2)^n\) contributions. Besides this, the equation includes those next-to-leading terms which provide the energy-momentum conservation during the evolution (or the iterations) and which takes care of the kinematic cutoff \( (5) \). These next-to-leading terms, account for the major part of the NLL and higher-order corrections to the original BFKL equation.

5 Discussion and outlook

Let us first discuss the equation proposed long ago in [7], since it describes some of the difficulties in obtaining a BFKL equation for an integrated gluon density. Formally Eq. \( (26) \) of [7] should be considered as the \( \ln(1/x) \) BFKL evolution equation for the integrated gluon density \( F(Q^2, S^2) \) with \( S^2 = \Lambda^2/x \) and with the splitting kernel \( P(Q^2/k^2; \alpha_s(S^2)) \) given by Eq. \( (30) \) of [7]. This equation is to be compared with our result \( (30) \) or Eq. \( (32) \). The first terms, corresponding to the real gluon emission with \( k_t < q \), or \( \kappa < 1 \) in [7], are the same. However, there is an important difference due to gluon reggeisation, which is not properly accounted for in [7]—reggeisation is a higher-twist effect, which cannot be reproduced by the ‘two-particle irreducible diagrams’ considered in [7]. Besides this, the kinematical constraint \( (5) \) for real gluon emission is missed in Eqs. \( (26, 30) \) of [7]. Moreover, strictly speaking, Eq. \( (26) \) assumes an infrared cutoff \( k_0 = 0 \); that is, it corresponds to the specific limit presented in Eq. \( (32) \) at the end of previous section. This was not emphasised in [7].

Another problem of Eq. \( (26) \) is the very strange choice of the argument, \( S^2 = \Lambda^2/x \), for the QCD coupling \( \alpha_s(S^2) \). Contrary to the natural choice, \( \alpha_s(q^2) \) as in Eq. \( (30) \), \( S^2 \) is very large at low \( x \) scales, and has the effect of completely killing the power growth \((x^{-\omega})\) of the BFKL amplitude since the value of \( \omega = \alpha_s \cdot \chi \) decreases as \( \alpha_s \propto 1/\ln(S^2) \propto 1/\ln(1/x) \). So from the evolution equation \( (26) \), with coupling \( \alpha_s(S^2) \), we would obtain a cross section which increases as some power of \( \ln(1/x) \), but not as a power of \( 1/x \).

Now we give an overview of the structure of unified DGLAP and BFKL evolution. As was emphasised in the introduction, the DGLAP equation sums up all the leading \((\alpha_s \ln Q^2)^n\) terms, while BFKL accounts for the \((\alpha_s \ln(1/x))^m\) contributions. In general, for many of the interesting processes at the LHC both logarithms are large, and are of the same order, so we need to consider evolution which takes care of these large logarithms. The DGLAP part describes the variation of the Parton Distribution Functions

\[ ^4 \text{Even for processes which depend directly on the gluon only at moderate and large values of } x, \text{ we need reliable knowledge of the gluon distribution at very small } x, \text{ since the normalisation of the gluon PDF is fixed by the energy-momentum sum rule. Note that a large part of the total energy of the gluon is hidden in the low } x \text{ domain where the gluon density is large and grows with decreasing } x. \]
(PDFs) with increasing values of the scale, \( Q^2 \); while BFKL evolution provides the correct small \( x \) behaviour.

Recall that DGLAP evolution starts from parameterised input distributions, PDF\(_{\text{input}}(x, Q_0^2)\) at a fixed scale \( Q^2 = Q_0^2 \), and it includes the trivial boundary condition, PDF = 0, at \( x = 1 \). On the other hand, BFKL evolution starts from a gluon distribution at a fixed, but not very small, value \( x = x_0 \). Its boundary condition, at relatively low values \( q^2 = Q^2 \), is driven by confinement. Confinement eliminates the gluon at large distances. Therefore, it looks natural for the BFKL case to have an analogous zero boundary condition, \( F(x, q = 0) = 0 \), which leads to the simplified form of the evolution given in Eq. (32).

Let us accept these, physically motivated, ‘zero’ boundary conditions. Then for unified BFKL–DGLAP evolution, we need DGLAP-like input in a limited interval of \( x \) only (say, from \( x_0 = 0.2 \) to 1). The BFKL input at fixed \( x = x_0 \) and \( q > q_0 \) is obtained now by a straightforward application of the DGLAP equation. The remaining part is the contribution from the small non-perturbative domain of \( q < q_0 \) and \( x > x_0 \). Here we may use an extrapolation like

\[
F(x, q < q_0) = F(x, q_0) \frac{q^2}{q_0^2},
\]

or, as used in [5], we may introduce a new parameter, \( q_a \), to allow for a better matching of the derivative at \( q = q_0 \)

\[
F(x, q < q_0) = F(x, q_0) \frac{q^2}{q_0^2} \left( \frac{q^2 + q_a^2}{q_0^2 + q_a^2} \right).
\]

In such an approach the phenomenological input distribution is used to describe the large \( x \) behaviour only, while the low \( x \) dependence is completely generated by BFKL.

Following from this development, it looks promising also to consider unified BFKL–DGLAP evolution for the integrated gluon PDF in terms of the variables \((x, \theta)\), as proposed in [16], instead of the variables \((x, q)\). The coherence of soft gluon emission automatically provides strong-ordering in the opening angle \( \theta = q_x/xp \) (where \( p \) is the momentum of the incoming proton). On the other hand, both the BFKL and the DGLAP logarithms are actually logarithms coming from an integration over \( d\theta/\theta \). Therefore, for evolution written in terms of \( \theta \), we may expect better accuracy already at LO level, with smaller higher-order corrections. Details of such a promising approach are given in [16], and a recent numerical study of evolution in \( \theta \) can be found in [17].

\footnote{In the more general case, we may use Eq. (30) with some input function \( F_{\text{input}}(x, q_0) \). In the original BFKL equation for unintegrated gluon density, the ‘input’ function \( f_0 \) (see Eq. (3)) reflects the contribution of the lowest-order (Born) diagram. Correspondingly, we do not expect the integrated input \( F_{\text{input}}(x, q_0) \) to grow as \( x \rightarrow 0 \). Rather, the growth of the gluon PDF at small \( x \) is generated by BFKL dynamics. Thus, anyway, the input distribution will be negligible in comparison with the strongly increasing PDF as we evolve to very low \( x \).}
