(Dated: February 1, 2008)

We propose an approximation to the ground state of Yang-Mills theory, quantized in temporal gauge and 2+1 dimensions, which satisfies the Yang-Mills Schrödinger equation in both the free-field limit, and in a strong-field zero mode limit. Our proposal contains a single parameter with dimensions of mass; confinement via dimensional reduction is obtained if this parameter is non-zero, and a non-zero value appears to be energetically preferred. A method for numerical simulation of this vacuum state is developed. It is shown that if the mass parameter is fixed from the known string tension in 2+1 dimensions, the resulting mass gap deduced from the vacuum state agrees, to within a few percent, with known results for the mass gap obtained by standard lattice Monte Carlo methods.

I. INTRODUCTION

Confinement is a property of the vacuum state of quantized non-abelian gauge theories, and it seems reasonable that something could be learned about the origin of confinement, and the origin of the mass gap, if we knew the form of the Yang-Mills vacuum wavefunctional in some physical gauge. There have, in fact, been a number of efforts along those lines, in temporal gauge [1–7], Coulomb gauge [8, 9], axial gauge [10], and in a Bars corner-variable formulation [11, 12].

In this article we will pursue this investigation in temporal gauge and in $D = 2 + 1$ dimensions, our strongest influences being refs. [1] and [7]. Our claim is that the ground state wavefunctional $\Psi_0[A]$ can be approximated by the form

$$\Psi_0[A] = \exp\left[-\frac{1}{2} \int d^2x d^2y \sqrt{-D^2 - \lambda_0 + m^2} B^a(x)y B^b(y)\right]$$

(1)

where $B^a = F^a_{12}$ is the color magnetic field strength, $D^2 = D_a D^a$ is the two-dimensional covariant Laplacian in the adjoint color representation, $\lambda_0$ is the lowest eigenvalue of $-D^2$, and $m$ is a constant, with dimensions of mass, proportional to $g^2$. To support this claim, we will argue that the above expression

1. is the ground state solution of the Yang-Mills Schrödinger equation in the $g \to 0$ limit;
2. solves the zero-mode Yang-Mills Schrödinger equation in the zero-mode strong-field limit;
3. confines if $m > 0$, and that $m > 0$ is energetically preferred;
4. results in the numerically correct relationship between the mass gap and string tension.

A very similar proposal for the vacuum wavefunctional, with $\lambda_0$ absent, was put forward by Samuel in ref. [7], generalizing the earlier “dimensional reduction” proposal of ref. [1].

Our paper is organized as follows: In section II, below, we find an approximate solution of the zero mode Yang-Mills Schrödinger equation in 2+1 dimensions, and compare this to our proposed wavefunctional in an appropriate limit. The dimensional reduction and confinement properties are discussed in section III. Section IV outlines a procedure for numerical simulation of our vacuum wavefunctional; in section V this procedure is applied to calculate the mass gap, with parameter $m$ chosen to give the correct string tension as a function of coupling. Confinement, in our approach, relies on $m > 0$; in section VI we will discuss why this choice lowers the vacuum energy in the non-abelian theory, while the minimum is at $m^2 = 0$ in the free abelian theory. Section VII contains a few results and critical comments regarding certain other proposals for the Yang-Mills vacuum wavefunctional. Some brief remarks about Casimir scaling and N-ality are found in section VIII, with conclusions in section IX.

We would like to note here that the work in section II, concerning the zero-mode strong-field limit, was motivated by a private communication from D. Diakonov to one of the authors [13].

II. THE FREE FIELD AND ZERO MODE LIMITS

In temporal gauge and $D = d + 1$ dimensions, the problem is to find the ground state of the Yang-Mills Schrödinger equation

$$H \Psi_0 = E_0 \Psi_0$$

(2)

where

$$H = \int d^d x \left\{-\frac{1}{4} \frac{\delta^2}{\delta A^a_i(x)} + \frac{1}{4} F^a_{ij}(x)^2\right\}$$

(3)

and all states in temporal gauge, in SU(2) gauge theory, are subject to the physical state condition

$$\left(\delta^{abc} \partial_k + g e^{abc} A^b_k\right) \frac{\delta}{\delta A^c_k} \Psi = 0$$

(4)

This condition requires invariance of $\Psi[A]$ under infinitesimal gauge transformations.
Our proposed vacuum wavefunctional, eq. (1), obviously satisfies the physical state condition, since the kernel

$$K_{a b} = \left( \frac{1}{\sqrt{-D^2 - \lambda_0 + m^2}} \right)_{x y}$$

transforms bilinearly, $K_{a b} \to U(x)K_{a b}U^{-1}(y)$, under a gauge transformation, with $U$ a transformation matrix in the adjoint representation. In the $g \to 0$ limit, with both $\lambda_0, m \to 0$ in the same limit, the vacuum state becomes

$$\left( \Psi_0[A] \right)_{x \to 0} = \exp \left[ -\frac{1}{2} \int d^2 x d^2 y \left( \partial_1 A_1^2(x) - \partial_2 A_1^2(x) \right) \right]$$

$$\left( \frac{\delta^{a b}}{\sqrt{V}} \right)_{x y} \left( \partial_1 A_1^2(y) - \partial_2 A_1^2(y) \right)$$

which is the known ground state solution in 2+1 dimensions, in the abelian, free-field case.

The Yang-Mills Schrödinger equation is also tractable in a quite different limit, which is, in a sense, diametrically opposed to the free-field situation. Let us restrict our attention to gauge fields which are constant in the two space directions, and vary only in time (analogous to the minisuperspace approximation in quantum gravity). The Lagrangian is

$L = \frac{1}{2} \int d^2 x \left[ \partial_1 A_k \cdot \partial_1 A_k - g^2 (A_1 \times A_2) \cdot (A_1 \times A_2) \right]$

where $V$ is the area of a time-slice, leading to the Hamiltonian operator

$H = -\frac{1}{2} \frac{\partial^2}{\partial A_k^2} + \frac{1}{2} g^2 V (A_1 \times A_2) \cdot (A_1 \times A_2)$

(8)

The factors of $V$ in the Hamiltonian suggest the use of a $1/V$ expansion. Let us write

$$\Psi_0 = \exp \left[ -V R_0 + R_1 + V^{-1} R_2 + ... \right]$$

(9)

with $R_0$ chosen such that the leading order (in $1/V$) “kinetic” term contained in $H \Psi_0$

$$-\frac{1}{2} V \partial R_0 \partial R_0 \partial A_k^2 \partial A_k^2$$

(10)

cancels the potential term

$$\frac{1}{2} g^2 V (A_1 \times A_2) \cdot (A_1 \times A_2)$$

at $O(V)$. Let

$$R_0 = \frac{\frac{1}{2} g (A_1 \times A_2) \cdot (A_1 \times A_2)}{\sqrt{|A_1|^2 + |A_2|^2}}$$

(12)

Then, defining

$$T_0 = V \left[ -\frac{\partial R_0 \partial R_0}{\partial A_k^2} \partial A_k^2 + g^2 (A_1 \times A_2) \cdot (A_1 \times A_2) \right]$$

it is not hard to verify that

$$T_0 = 0 + \frac{7}{4} g^2 V \left[ (A_1 \times A_2) \cdot (A_1 \times A_2) \right]^2 \left( |A_1|^2 + |A_2|^2 \right)^2$$

$$= \frac{7V R_0^2}{|A_1|^2 + |A_2|^2}$$

(14)

Now for $A$-fields for which $\Psi_0$ is non-negligible, it is easy to see that $T_0 \Psi_0$ is of order no greater than $1/V$, except in the immediate neighborhood of the origin ($A_k = 0$ of field space. That is because $\Psi_0 \approx \exp [-V R_0]$, which is non-negligible only if $V R_0$ is $O(1)$. For comparison with eq. (1) we are interested in a strong-field limit, far from the origin of field space. In that case, since $R_0 \sim 1/V$, then the rhs of (14) is at most of order $1/V$, which can be neglected. It follows that $R_0$ in eq. (12) accomplishes the required cancellation at leading order, and provides the leading contribution to the logarithm of the vacuum wavefunction.

Now consider the proposal (1) for the vacuum wavefunctional of the full theory, in a corner of field space where the non-zero momentum modes of the $A$-field are negligible compared to the zero modes, and in fact the zero modes are so large in magnitude that we can approximate $D^2 \approx g_{a b} A_k^a A_k^b$.

In this region

$$(-D^2)^{a b}_{x y} = g^2 \delta^{x y} (x - y) M^{a b}$$

(15)

where

$$M^{a b} = (A_1^2 + A_2^2) \delta^{a b} - A_1^2 A_1^b - A_2^2 A_2^b$$

(16)

In SU(2) gauge theory, the two zero-mode fields $A_1, A_2$ define a plane in three-dimensional color space. Take this to be, e.g., the color $x - y$ plane, i.e.,

$$A_1 = \begin{bmatrix} a_1 \\ a_2 \\ 0 \end{bmatrix}, \ A_2 = \begin{bmatrix} b_1 \\ b_2 \\ 0 \end{bmatrix}$$

(17)

Then

$$M = \begin{pmatrix} a_1^2 + b_2^2 & -a_1 a_2 - b_1 b_2 & 0 \\ -a_1 a_2 - b_1 b_2 & a_1^2 + b_2^2 & 0 \\ 0 & 0 & A_1^2 + A_2^2 \end{pmatrix}$$

(18)

Now $M$ has three eigenstates

$$\phi_1 = \begin{bmatrix} \phi_1^1 \\ \phi_1^2 \\ 0 \end{bmatrix}, \ \phi_2 = \begin{bmatrix} \phi_2^1 \\ \phi_2^2 \\ 0 \end{bmatrix}, \ \phi_2 = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$$

(19)

with corresponding eigenvalues

$$\mu_1 = \frac{1}{2} \left( S - \sqrt{S^2 - 4C} \right)$$

$$\mu_2 = \frac{1}{2} \left( S + \sqrt{S^2 - 4C} \right)$$

$$\mu_3 = S$$

(20)
where

\[ S = A_1^2 + A_2^2, \quad C = (A_1 \times A_2) \cdot (A_1 \times A_2) \quad (21) \]

Then

\[ \left( \frac{1}{\sqrt{M - (\mu_1 - m^2)i}} \right)^{ab} = \sum_{n=1}^{3} \frac{\phi_n^{a} \phi_n^{b}}{\sqrt{\mu_n - \mu_1 + m^2}} \quad (22) \]

We have

\[
\Psi_0 \approx \exp \left[ -\frac{1}{2} \int d^2x d^2y B^a(x) \left( \frac{1}{\sqrt{-D^2 - \lambda_0 + m^2}} \right)^{ab} B^b(y) \right] = \exp \left[ -\frac{4 g^2 V (A_1 \times A_2)^a}{\sqrt{g^2 (M - \mu_1 I) + m^2 I}} \right]^{ab} (A_1 \times A_2)^b \quad (23)
\]

Taking account of eqs. (17), (19) and (22), we get

\[
\Psi_0 = \exp \left[ -\frac{1}{2} g V (A_1 \times A_2)^3 \left( \frac{1}{\sqrt{M - \mu_1 I + m^2 I}} \right) \right]^{ab} (A_1 \times A_2)^3
\]

\[ = \exp \left[ -\frac{1}{2} g V (A_1 \times A_2) \cdot (A_1 \times A_2) \right]^{ab} \left( A_1 \times A_2 \right) \quad (24)
\]

Now by assumption, in the strong-field limit,

\[ g^2 \mu_3 = g^2 (A_1^2 + A_2^2) \gg m^2 \quad (25) \]

and

\[ \mu_1 = \frac{1}{2} S \left( 1 - \sqrt{1 - \frac{4 C}{S^2}} \right) \approx \frac{C}{S} \]

\[ \approx \frac{2}{g} R_0 \quad (26) \]

We recall that the ground-state solution of the zero-mode Schrödinger equation \( \Psi_0 = \exp[-VR_0] \) with \( R_0 \) given in eq. (12) is valid for \( R_0 \sim 1/V \), where the wavefunction is non-negligible. In this same region of configuration space, \( \mu_1 \) is negligible compared to \( \mu_3 \), and eq. (24) becomes

\[
\Psi_0 = \exp \left[ -\frac{1}{2} g V (A_1 \times A_2) \cdot (A_1 \times A_2) \right]^{ab} \left( A_1 \times A_2 \right) \quad (27)
\]

which is identical to the solution found for the ground state of the zero-mode Schrödinger equation, in the region of validity of that solution, where \( VR_0 \sim O(1) \). Therefore, in a small region of configuration space where a non-perturbative treatment is possible, we find that our ansatz for the vacuum state agrees with the ground state of the zero-mode Yang-Mills Schrödinger equation.\(^1\)

The argument above can also be extended to 3+1 dimensions, as outlined in Appendix A.

### III. DIMENSIONAL REDUCTION AND CONFINEMENT

Assuming that our proposal (1) for the Yang-Mills vacuum wavefunctional in 2+1 dimensions is at least approximately correct, then where does the confinement property appear?

A long time ago it was suggested that the effective Yang-Mills vacuum wavefunctional at large scales, in \( D = d + 1 \) dimensions, has the form [1]

\[ \Psi_0^{eff} \approx \exp \left[ -\mu \int d^d x F_{ij}^a(x) F_{ij}^a(x) \right] \quad (28) \]

(see also [3, 5]). This vacuum state has the property of “dimensional reduction”: Computation of a large spacelike loop in \( d + 1 \) dimensions reduces to the calculation of a large Wilson loop in \( d \) Euclidean dimensions. Suppose \( \Psi_0^{(3)} \) is the ground state of the 3+1 dimensional theory, and \( \Psi_0^{(2)} \) is the ground state of the 2+1 dimensional theory. If these ground states both have the dimensional reduction form, and \( W(C) \) is a large planar Wilson loop, then the area law falloff in \( D = 3 + 1 \) dimensions follows from confinement in two Euclidean dimensions in two steps:

\[ W(C) = \left\langle \text{Tr}[U(C)] \right\rangle_{D=4}^{D=3} = \left\langle \Psi_0^{(3)} \left| \text{Tr}[U(C)] \right| \Psi_0^{(3)} \right\rangle \]

\[ \sim \left\langle \text{Tr}[U(C)] \right\rangle_{D=3}^{D=2} = \left\langle \Psi_0^{(2)} \left| \text{Tr}[U(C)] \right| \Psi_0^{(2)} \right\rangle \]

\[ \sim \left\langle \text{Tr}[U(C)] \right\rangle_{D=2} \quad (29) \]

In \( D = 2 \) dimensions the Wilson loop can of course be calculated analytically, and we know there is an area-law falloff, with Casimir scaling of the string tensions. The dimensional reduction form of the ground state wavefunctional can be demonstrated explicitly in strong-coupling lattice gauge theory [2]; Monte Carlo support for the hypothesis has also been obtained at intermediate couplings [14, 15].

It is natural to try and improve on the dimensional reduction idea by considering wavefunctionals which interpolate, in some natural way, between free-field dynamics at short distance scales, and the dimensional reduction form at large scales. In ref. [7], Samuel suggested that the vacuum state in

\[ ^1 \text{We learned from D. Diakonov that he had obtained this result in unpublished work, which considered a wavefunctional of similar form to (1) but without the } \lambda_0, m \text{ terms in the kernel [13]. Those terms are not important in the region of configuration space discussed in this section.} \]
$D = 2 + 1$ dimensions might have the form

$$\Psi_0[A] = \exp \left[ -\frac{1}{4} \int d^2 x d^2 y \, B^a(x) \left( \frac{1}{\sqrt{-D^2 + m_0^2}} \right) B^b(y) \right]$$

(30)

Our proposal differs from Samuel’s in that $m_0^2$ is replaced by $-\lambda_0 + m^2$, with the lowest eigenvalue $\lambda_0$ being field-dependent and gauge-invariant. The rationale is that we should allow for a subtraction in the operator $-D^2$ appearing in the vacuum kernel: a subtraction will be absolutely required if the spectrum of $-D^2$, starting with $\lambda_0$, diverges in the continuum limit. On the other hand, if $m_0^2 < 0$ is a negative constant, then the wavefunctional in eq. (30) is not necessarily real throughout configuration space, and can oscillate. Now the true vacuum state must be real up to a constant factor, and it is forbidden to pass through zero by the “no node” theorem for quantum-mechanical ground states. Requiring a subtraction which respects the reality of the wavefunctional, and avoids oscillations anywhere in field configuration space, dictates the replacement

$$m_0^2 \rightarrow -\lambda_0 + m^2$$

(31)

with $m^2 \geq 0$.

The dimensional reduction form is obtained by dividing the field strength into “fast” and “slow” components, defined in terms of a mode cutoff. Let $\{ \phi_n^a \}$ and $\{ \lambda_n \}$ denote the eigenmodes and eigenvalues, respectively, of the covariant Laplacian operator in adjoint color representation, i.e.

$$-(D^2)_{ab} \phi_n^a \phi_n^b = \lambda_n \phi_n^a$$

(32)

The field strength can be expanded as a mode sum

$$B^a(x) = \sum_{n=0}^{\infty} b_n \phi_n^a(x)$$

(33)

and we define the "slow" component to be

$$B^{a,slow}(x) = \sum_{n=0}^{n_{max}} b_n \phi_n^a(x)$$

(34)

where $n_{max}$ is a mode cutoff chosen such that $\Delta \lambda \equiv \lambda_{n_{max}} - \lambda_0 \ll m^2$ remains fixed as $V \rightarrow \infty$. In that case, the portion of the (squared) vacuum wavefunctional gaussian in $B^{slow}$ is approximately

$$\exp \left[ -\frac{1}{m} \int d^2 x \, B^{a,slow} \left( B^{a,slow} B^b \right) \right]$$

(35)

which is just the probability measure for Yang-Mills theory in two Euclidean dimensions, with a particular type of ultraviolet cutoff. The string tension for fundamental representation Wilson loops in $D = 2$ Yang-Mills theory, with coupling $g^2 m$, is easily computed:

$$\sigma = \frac{3}{16} g^2 m$$

(36)

or in lattice units, with lattice coupling $\beta$,

$$\sigma = \frac{3 m}{4 \beta}$$

(37)

In the next sections we will address two questions. First, suppose we fix $m$ to give the known string tension at a given lattice coupling. What is then the value of the mass gap predicted by the vacuum wavefunctional, and to what extent does this agree with the corresponding value determined by standard lattice Monte Carlo methods? Secondly, since confinement depends on having $m \neq 0$, is there any reason why the mass parameter $m$ should be non-zero?

IV. NUMERICAL SIMULATION OF THE VACUUM WAVEFUNCTIONAL

The mass gap implied by the vacuum state (1) can, in principle, be extracted from the equal-times connected correlator

$$\mathbb{D}(x - y) = \langle (B^a B^b)_x (B^a B^b)_y \rangle - \langle (B^a B^b)_x \rangle^2$$

(38)

where the expectation value is taken with respect to the probability distribution $P[A]$ defined by the vacuum wavefunctional, i.e.

$$\langle Q \rangle = \int DA_1 DA_2 \, Q[A] P[A]$$

(39)

with

$$P[A] = |\Psi_0[A]|^2$$

$$= \exp \left[ -\frac{1}{g^2} \int d^2 x d^2 y \, B^a(x) K_{xy}^{ab}[A] B^b(y) \right]$$

(40)

and

$$K_{xy}^{ab}[A] = \left( \frac{1}{\sqrt{-D^2 - \lambda_0 + m^2}} \right)_{xy}^{ab}$$

(41)

Here we have absorbed a factor of $g$ into the definition of $A_i$, which accounts for the factor of $1/g^2$ in the exponent in eq. (40).

It not easy to see how $\mathbb{D}(x - y)$ could be computed analytically beyond the level of weak-coupling perturbation theory, but computation by numerical simulation of $P[A]$ also seems hopeless, at least at first sight. Not only is the kernel $K_{xy}^{ab}$ non-local, it is not even known explicitly for arbitrary $A_i^a(x)$. However, suppose that after eliminating the wild variations of $K$ along gauge orbits via a gauge choice, $K[A]$ has very little variance among thermalized configurations. In that case, things are more promising.

Let us define a probability distribution for gauge fields $A$ which is controlled by a second, independent configuration $A'$

$$P[A; K[A']] = \det^{1/2} \left( \frac{1}{g^2} K[A'] \right) \exp \left[ -\frac{1}{g^2} \int d^2 x d^2 y \, B^a(x) K_{xy}^{ab}[A'] B^b(y) \right]$$

(42)
where the field strength $B$ is computed from the $A$-configuration, and both $A$ and $A'$ are fixed to some appropriate gauge. Now, assuming that the variance of $K[A]$ in the probability distribution $P[A]$ is small after the gauge choice, we can approximate

$$P[A] \approx P[A, \langle K \rangle]$$

$$= P[A, \int DA' K[A'][P[A']]]$$

$$\approx \int DA' P[A, K[A']][P[A']]$$

(43)

where the step from the second to the third line follows from assuming that the variance of $K$ in the distribution $P[A]$ is small. If this assumption about $K[A]$ is correct, and eq. (43) holds, then the probability distribution could in principle be generated by solving (43) iteratively:

$$P^{(1)}[A] = P[A; K[0]]$$

$$P^{(n+1)}[A] = \int DA' P[A; K[A']][P^{(n)}[A']]$$

(44)

A numerical version of this approach would be to use equilibrium configurations of $P^{(n)}[A]$, generated at the $n$-th step, to generate equilibrium configurations of $P^{n+1}[A]$ at the $(n+1)$-th step.

We may use the remaining gauge freedom to fix to an axial gauge in the two-dimensional time slice. This allows us to change variables in the functional integral over two-dimension configurations from $A'_{xy}$, $A^a_{xy}$ to $B^a$, without introducing a field-dependent Jacobian. Let eigenvalues $\lambda_n$, and eigenmodes $\phi_n^a$ solve the eigenvalue equation

$$-D^2\phi_n = \lambda_n\phi_n$$

(45)

for the covariant Laplacian $-D^2$ determined from the fixed $A'$ configuration, and let $\{b_n\}$ be the mode amplitudes of the $B$-field, as seen in the mode expansion (33). Then the probability distribution for the $\{b_n\}$, which follows from $P[A; K[A']][A']$ at fixed $A'$, is Gaussian

$$\text{prob}[b_n] \propto \exp \left[ \frac{-\beta}{4\sqrt{\lambda_n - \lambda_0 + m^2}} b_n^2 \right]$$

(46)

In practice we use a lattice regularization on an $L \times L$ lattice with periodic boundary conditions, and the gauge field $A^a_{xy}(x, y)$ is initialized to zero at the first iteration. We then generate gauge fields recursively; the procedure at the $n$-th iteration is as follows:

1. From one of the lattice configurations generated at the $(n-1)$-th iteration, compute the link variables in the adjoint representation, and then determine numerically the eigenvalues and eigenmodes of the two-dimensional lattice covariant Laplacian operator $-D^2$.

2. Generate a set of $3L^2$ normally-distributed random numbers with unit variance, denoted $\{r_n\}$. From these, we obtain a new set of mode amplitudes

$$b_n = \sqrt{\frac{2}{\beta}} (\lambda_n - \lambda_0 + m^2)^{1/4} r_n$$

(47)

and a corresponding $B$-field

$$B^a(x) = \sum_{n=0}^{\infty} b_n \phi_n^a(x)$$

(48)

From the field strength $B^a(x)$, and the axial gauge condition, determine the corresponding gauge field $A^a_{xy}(x)$. This step can be repeated to generate as many thermalized configurations of $P[A, K[A']]$ as desired.

3. The gauge fields are exponentiated to give link variables

$$U_k(x, y) = \exp[iA^a_{xy}(x, y)\sigma_a/2]$$

(49)

and any observables of interest are computed. This concludes the $n$-th iteration.

Lattice configurations generated by this procedure will be referred to as “recursion lattices”.

Details about our particular choice of axial gauge on a finite lattice, and the procedure for obtaining the $A$-field from the $B$-field in that gauge, may be found in Appendix B.

V. THE MASS GAP

The simulation procedure outlined in the last section leans heavily on the assumption that there is little variance in the kernel $K_{xy}$ in a fixed gauge, or, equivalently, that there is negligible variance, among thermalized configurations, in gauge-invariant combinations of the kernel such as $\text{Tr}[K_{xy}^{-1}K_{xy}^{-1}]$, or in the gauge-invariant spectrum of $K$. The absence of significant fluctuations in these quantities, when evaluated numerically, is a self-consistency requirement of the method we have proposed. The quantity $\text{Tr}[K_{xy}^{-1}K_{xy}^{-1}]$ is of particular interest, because its rate of falloff at large $|x - y|$ is determined by the mass gap.

We begin with the spectrum $\{\lambda_n - \lambda_0 + m^2\}$ of the operator $-D^2 - \lambda_0 + m^2$, with $m$ chosen, at a given $\beta$, to reproduce the string tension $\sigma(\beta)$ known from Monte Carlo simulations of the standard Wilson action in three Euclidean dimensions [16]. From eq. (37), this means choosing

$$m = \frac{4}{3} \beta \sigma(\beta)$$

(50)

The result for the spectrum at $\beta = 18$ on a $50 \times 50$ lattice is shown in Fig. 1. The figure displays our results for ten separate recursion lattices, as well as the zero-field result $-\nabla^2 + m^2$ for a very large volume lattice, with the eigenmode numbers rescaled by the factor $50^2/V$, so as to fit in the same range on the $x$-axis as the other ten data sets. It can be seen that, at the resolution of this figure, the spectra essentially all fall on top of one other. The ten separate data
FIG. 1: Ten sets of eigenvalue spectra of the operator $-D^2 - \lambda_0 + m^2$, at $\beta = 18$, from ten independent $50 \times 50$ recursion lattices. Also plotted, but indistinguishable from the other spectra, is the rescaled spectrum of the large-volume zero-field operator. 

The closely spaced dots are from ten sets of eigenvalue spectra. The “+” symbols are taken from the rescaled spectrum of the large-volume zero-field operator.

Next we turn to the computation of the mass gap. According to eq. (43),

$$\langle Q \rangle = \int DA_1 DA_2 Q[A]P[A]$$

$$\approx \int DA_1 DA_2 DA_3 DA_4 Q[A]P[A,K[A']]P[A']$$

$$= \int DBDA_1 DA_2 Q[A(B)]P[A(B),K[A']]P[A']$$

(51)

where we have changed variables, in an axial gauge, from gauge field $A$ to field strength $B$ as discussed in the last section. Evaluating in this way the rhs of (38) with $P[A,K[A']]$ as defined by eq. (42), the integration over $B$ is gaussian, and we find

$$\mathcal{D}(R) = \frac{8}{\beta^2} G(R)$$

(52)

where $R = |x - y|$ and (no sum over $x,y$)

$$G(R) = \langle (K^{-1})_{xy}^{ab}(K^{-1})_{yx}^{ba} \rangle$$

$$K^{-1} = \sqrt{-D^2 - \lambda_0 + m^2}$$

(53)

Of course, the expectation value of $(K^{-1})_{xy}^{ab}(K^{-1})_{yx}^{ba}$ can also be evaluated by standard lattice Monte Carlo methods based on the $D = 3$ dimensional Wilson action. A number of thermalized lattices are generated by the usual heat bath procedure, and $K^{-1}$ is evaluated on a two-dimensional constant-time slice of each three-dimensional lattice. The two-dimensional lattices generated in this way will be referred to as “MC lattices”. They can be thought of as having been drawn from a probability weighting $P[U] = \Psi_{k,0}[U]$, where $\Psi_{k,0}[U]$ is the ground state of the transfer matrix of the $D = 3$ dimensional Euclidean lattice gauge theory.

FIG. 2: Same as Fig. 1, for the lowest 200 eigenmodes. The closely spaced dots are from ten sets of eigenvalue spectra. The “+” symbols are taken from the rescaled spectrum of the large-volume zero-field operator.

FIG. 3: The correlator $G(R)$ computed (i) on two-dimensional lattice configurations generated from the vacuum wavefunctional by the method described in the text; and (ii) on constant-time slices of three-dimensional lattice configurations generated by the usual lattice Monte Carlo method. Lattices generated by the first method are denoted “recursion”, and by the second as “MC”. In each case, the lattice extension is 50 sites at $\beta = 18$.

Figure 3 shows the data for $G(R)$ at $\beta = 18$, averaged from a set of ten $50 \times 50$ recursion lattices, and, for comparison, corresponding data averaged from a set of ten $50 \times 50$ MC lattices at $\beta = 18$. Note the very small ($\sim O(10^{-12})$) magnitude of the observable at $R = 20$, yet even at this magnitude there seems to be very little noisiness in the data. Once again, this absence of noise is only possible if the variance in the $K^{-1}K^{-1}$ observable is negligible, which supports our original
hypothesis. Moreover, the data obtained on recursion and MC lattices obviously agree very well with each other.

The mass gap is obtained by fitting the data for $G(R)$ to an appropriate functional form, and extracting the exponential falloff. Define

$$ G_0(R) = \exp\left[ -\frac{\lambda_0}{2} \left( \sqrt{-\nabla^2 + \mu^2} \right)^2 \right] $$

$$ = \frac{3}{4R^2} \left[ 1 + \mu R \right]^2 e^{-2\mu R/R_0} $$

(54)

We have seen (Fig. 1) that the spectrum of $-D^2 - \lambda_0$ is almost identical to that of the zero-field Laplacian $-\nabla^2$. With this motivation, we introduce the fitting function

$$ f_0(R) = \log \left[ a(1 + M R)^2 e^{-M R} \right] $$

(55)

and carry out a two parameter ($a$ and $M$) best fit of $\log[G(R)]$ by $f_0(R)$.$^2$ The resulting value for $M$ is an estimate of the mass gap. The best fit of the data for $G(R)$ at $\beta = 18$ on a 50$^2$ lattice by the fitting function $\exp[f_0(R)]$ is shown in Fig. 4.

In an old paper which anticipates the work in this section, Samuel [7] argued that $M \approx 2m_0$, where $m_0$ is the mass parameter in the vacuum state (30) which he proposed. This result is obtained if the covariant operator $-D^2$ in (30) is replaced by $-\nabla^2$. We believe that a more natural approximation is the replacement of $-D^2 - \lambda_0$ by $-\nabla^2$, since the lowest eigenvalue in the spectrum of each operator begins at zero. Thus the “naive” estimate for the mass gap, in our proposal, is $M = 2m$.

The results of extracting $M$ via the best fit of $f_0$ to the data, for simulations of the vacuum wavefunctional at a variety of lattice couplings, are shown in Fig. 5. There we compare our values for the mass gap with those reported by Meyer and Teper in ref. [16] (the values for $\sigma(\beta)$, used in eq. (50), were also taken from this reference.) In Table I we list these mass gap results, as well as the mass gaps extracted from MC lattices, and the “naive” estimate $M(0^+) = 2m$. It can be seen that the agreement between the reported values for the mass gap, and the masses we have obtained from simulation of our proposed wavefunctional (with parameter $m$ fixed to give the observed asymptotic string tension), agree within a few (< 6) percent. This is a substantial improvement over the “naive” estimate of $M = 2m$, which disagrees with the Monte Carlo results by up to 20%.

TABLE I: The mass gaps in D=2+1 dimensional Yang-Mills theory, at a variety of $\beta$ values and lattice sizes $L^2$. Column 3 shows the values derived from the estimate $M = 2m$, and the values extracted from $G(R)$ computed on MC lattices are shown in column 4. Column 5 displays the results extracted from $G(R)$ computed from recursion lattices; these are the predictions obtained from numerical simulation of the vacuum wavefunctional. All of these values can be compared to the mass gaps reported in ref. [16], shown in column 6, which were obtained by conventional lattice Monte Carlo methods.

---

$^2$ The fits were carried out by the GNUPLOT package, which implements the Marquardt-Levenberg fitting algorithm. We have fit the data for $\log(G(R))$ on an $L \times L$ lattice in the interval $R \in [1, L/2]$. Errorbars are estimated from the variance in mass gaps computed separately, at each $\beta$, on ten independent lattices.
VI. VACUUM ENERGY AND CONFINEMENT

Our proposed vacuum wavefunctional results in a non-vanishing asymptotic string tension, via the dimensional reduction argument, for any mass parameter \( m > 0 \). In this context, the question of why pure SU(2) gauge theory confines in 2+1 dimensions boils down to why \( m \) is non-zero in that case, yet \( m = 0 \) in the abelian theory. The answer must lie in energetics: For some reason the expectation value of \( \langle H \rangle \) is lowered, in the non-abelian theory, by having \( m > 0 \).

The calculation of \( \langle H \rangle \) is complicated by functional derivatives of the kernel \( K[A] \). In this initial study we will simply ignore these derivatives, on the grounds that variance of the gauge-invariant product \( K^{-1}K \) among thermalized configurations has been found, in numerical simulations, to be negligible. In fact, this product seems to be remarkably well approximated, in any thermalized configuration, by the free-field limit. In fact, we are not as yet able to quantify the actual error which might be justified. However, we are not as yet able to quantify the actual error which is made by dropping those derivatives.

Writing \( \Psi_0 = \exp(-R[A]) \) where

\[
R = -\frac{1}{2g^2} \int d^2x d^2y \, B^a(x)K^{ab}_{xy}B^b(y)
\]

we find

\[
H\Psi_0 = \left(T_0 - T_1 + \frac{1}{2g^2} \int d^2x \, B^2 \right) \Psi_0
\]

where

\[
T_0 = \frac{g^2}{2} \int d^2x \, \frac{\delta^2 R}{\delta A^a_k(x)^2}
\]

\[
T_1 = \frac{g^2}{2} \int d^2x \, \frac{\delta R}{\delta A^a_k(x)} \frac{\delta R}{\delta A^b_k(x)}
\]

Carrying out the indicated functional derivatives of \( R \), but dropping terms involving functional derivatives of the kernel \( K \) leads to

\[
T_0 = \frac{1}{2} \int d^2x d^2y \, \delta(x-y)(-D^2)^ab K^{ba}_{xy}
\]

\[
= \frac{1}{2} \text{Tr} \left\{ (-D^2) \frac{1}{\sqrt{-D^2 - \lambda_0 + m^2}} \right\}
\]

and

\[
T_1 = \frac{1}{2g^2} \int d^2x d^2y \, B^a(x) \left[ \frac{-D^2}{\sqrt{-D^2 - \lambda_0 + m^2}} \right]^{ab}_{xy} B^b(y)
\]

\[
= \frac{1}{2g^2} \int d^2x d^2y \, B^a(x) \left[ 1 + \frac{\lambda_0 - m^2}{D^2 - \lambda_0 + m^2} \right]^{ab}_{xy} B^b(y)
\]

Expanding \( B(x) \) in eigenstates of \( -D^2 \)

\[
B^a(x) = \sum_n b_n \Phi_n^a(x)
\]

the second term on the rhs of eq. (61) becomes

\[
2\text{nd term} = \frac{1}{2} \langle \lambda_0 - m^2 \rangle \int d^2x \, B^2 \frac{1}{\sqrt{-D^2 - \lambda_0 + m^2}}
\]

which leads to

\[
\langle H \rangle = \frac{1}{2} \left\{ \text{Tr} \frac{-D^2}{\sqrt{-D^2 - \lambda_0 + m^2}} - \frac{1}{2} \text{Tr} \frac{\lambda_0 - m^2}{\sqrt{-D^2 - \lambda_0 + m^2}} \right\}
\]

Defining

\[
\tilde{k}_n^2 = \lambda_n - \lambda_0
\]

we finally obtain

\[
\langle H \rangle = \frac{1}{2} \sum_n \left( \sqrt{\tilde{k}_n^2 + m^2} + \frac{\lambda_0 - m^2}{\sqrt{\tilde{k}_n^2 + m^2}} \right)
\]

Suppose that the expectation value of the eigenvalues \( \lambda_n \) were independent of \( m^2 \), with zero variance, as in the free theory. Setting \( \partial \langle H \rangle / \partial m^2 = 0 \), the minimum vacuum energy is obtained trivially, at \( m^2 = \langle \lambda_0 \rangle \). In the abelian free-field limit we have \( \lambda_0 = 0 \), so \( m = 0 \) at the minimum and the theory is not confining. In the non-abelian theory, in contrast, \( \lambda_0 > 0 \), so \( m^2 = \lambda_0 > 0 \) at the minimum, and confinement is obtained. Of course, this simple result neglects both the \( m^2 \)-dependence of the eigenvalue spectrum, as well as contributions arising
\[ \beta = \text{improved on somewhat, at least regarding the } \text{dependence, by a numerical treatment.} \]

A Monte Carlo evaluation of the energy density \( \langle H \rangle / L^2 \) as a function of \( m \), for \( \beta = 6 \) and \( L = 16 \) and \( \langle H \rangle \) as given in eq. (67), is shown in Fig. 6. The minimum of this section is away from zero, at roughly \( m = 0.3 \). This gives a string tension which is a little low: the known string tension of the Euclidean theory at \( \beta = 6 \) would require \( m = 0.515 \). This quantitative disagreement should not be taken too seriously, because the estimate for vacuum energy on which it is based, eq. (67), is of unknown accuracy. Once again, in deriving (67), we have neglected some terms deriving from functional derivatives of the kernel. Even assuming, as we have, that those contributions are quite small (and this has not been shown), they could still have a large effect on the position of the minimum of a rather flat potential. The main point of this section is not to obtain \( m \) with any degree of accuracy (although that would have been desirable), but rather just to see that a non-zero value of \( m \), which implies both confinement and a mass gap, is the natural outcome of a variational calculation.

**VII. OTHER PROPOSALS**

There have been other approaches to the Yang-Mills vacuum state in 2+1 dimensions. In particular, the vacuum wavefunctional proposed by Karabali, Kim, and Nair (KKN) in ref. [11] has some strong similarities to ours, and the method we have developed for numerical simulation can be applied to the KKN vacuum state, as well as to our own proposal. This application is important, because we would like to test the claim that a string tension can be derived from the KKN state which agrees, to within a few percent, with the continuum limit of string tensions extracted from lattice Monte Carlo [17].

The KKN approach is formulated in terms of gauge-invariant field variables first introduced by Bars [18], and the idea is to solve for the ground state of the Hamiltonian, in these variables, in powers of the inverse coupling \( 1/g^2 \). To lowest order, when re-expressed in terms of the usual A-field variables, their state has the dimensional reduction form

\[
\Psi_0^{(0)} = \exp \left[ -\frac{1}{4mg^2} \int d^2 x B^a(x) B^a(x) \right] \tag{68}
\]

where

\[
m = \frac{g^2 C_A}{2\pi} \tag{69}
\]

and \( C_A \) is the quadratic Casimir for the SU(N) group in the adjoint representation. Because this state has the dimensional reduction form, the corresponding string tension is easily deduced. In lattice units, for the SU(2) group, the predicted string tension is

\[
\sigma_{KKN}^{(0)} = \frac{6}{\pi g^2} \tag{70}
\]

which is in rather close agreement with the lattice Monte Carlo results.

However, the state \( \Psi_0^{(0)} \) is only the first term in a strong-coupling series. As it stands, it implies an infinite glueball mass in 2+1 dimensions, and it cannot be even approximately correct at short distance scales. The question is whether inclusion of the higher-order terms in the series, which are necessary in order to have a non-zero correlation length, will affect the long-distance structure, and move the prediction for the string tension away from the desired value. KKN resum all of the terms in the strong-coupling series which are bilinear in their field variables, and when this expression is converted back to ordinary A-field variables, their resummed vacuum state has the form

\[
\Psi_0 \approx \exp \left[ -\frac{1}{2g^2} \int d^2 x d^2 y B^a(x) \left( \frac{1}{\sqrt{-\nabla^2 + m^2 + m}} \right)_{xy} B^a(y) \right] \tag{71}
\]

This state is gauge non-invariant as it stands, and for that reason must be incomplete. However, KKN argue that the further terms in the strong-coupling series, involving higher powers of the field variables and their derivatives, supply the extra terms required to convert the \( \nabla^2 \) operator in eq. (71) to a covariant Laplacian. So, according to ref. [11], the vacuum state when re-expressed in ordinary variables has the form

\[
\Psi_0 \approx \exp \left[ -\frac{1}{2g^2} \int d^2 x d^2 y B^a(x) \left( \frac{1}{\sqrt{-D^2 + m^2 + m}} \right)_{xy}^{ab} B^b(y) \right] \tag{72}
\]

In this form, the KKN vacuum state is amenable to the numerical methods described above.

At this point we see that there may be trouble ahead for the previous string tension prediction. The problem is that the
TABLE II: A comparison of the string tension $\sigma_{KKN}$ calculated numerically from the Karabali-Kim-Nair vacuum wavefunctional (72), by methods developed above, with the values of the string tension $\sigma_{MC}$ in $D = 3$ dimensions, computed by standard lattice Monte Carlo methods in ref. [16].

| $\beta$ | $L^2$ | $\sigma_{KKN}$ | $\sigma_{MC}$ | discrepancy |
|---------|-------|-----------------|----------------|-------------|
| 9       | 24$^2$ | 0.0340(4)       | 0.0261(2)      | 30%         |
| 12      | 32$^2$ | 0.0201(6)       | 0.0139(1)      | 45%         |

The Casimir scaling of string tensions is inevitable for the lattice Yang-Mills action in two spacetime dimensions, and therefore this scaling, out to infinite charged source separations, seems to be a consequence of dimensional reduction to two dimensions. This feature cannot be true for the asymptotic string tension in $2+1$ and $3+1$ dimensions, except in the $N_c = \infty$ limit. Asymptotic string tensions in $D=2+1$ and $3+1$ dimensions must depend only on the $N$-ality of the charged source, due to color screening by gluons. The absence of color screening in $D = 2$ dimensions can be attributed to the fact that a gluon has $D - 2$ physical degrees of freedom in $D$ dimensions. In two dimensions there are no physical degrees of freedom corresponding to propagating gluons. If there are no gluons there can be no string-breaking via dynamical gluons, and hence no $N$-ality dependence.

However, the vacuum state of a $d + 1$-dimensional gauge theory in temporal gauge does not, in general, describe a $d$-dimensional Euclidean Yang-Mills theory, despite the fact that each is expressed in terms of a gauge-invariant combination of d-dimensional vector potentials. For example, the vacuum state of the $2 + 1$-dimensional abelian theory, shown in eq. (6), describes the ground state of a theory of free, non-interacting photon states with a global SU(2) invariance. Our proposed vacuum state in eq. (1) interpolates between a theory of non-interacting gluons at short distances, and the dimensional reduction form (28) at large scales. If this is the correct vacuum, then at intermediate distance scales it describes the ground state of strongly interacting gluons with physical degrees of freedom; these gluons are free to bind with an external source. In that case, the Minkowski-space picture of string-breaking via gluon pair production should somehow carry over to $N$-ality dependence for Wilson loops evaluated in the vacuum state at a fixed time.³

At present this is only an optimistic speculation, but the following observation may be relevant: It is possible to compute the ground state $\Psi_0[U]$ in strong-coupling Hamiltonian lattice gauge theory, and to identify the term in that ground state which is responsible for color screening. From the expansion of this term in powers of the lattice spacing, we can identify the leading correction to dimensional reduction. It turns out

³ The transition from Casimir scaling to $N$-ality dependence, due to gluon string-breaking effects, is very likely to be associated with a vacuum center domain structure, as discussed recently in ref. [19]. Gluon charge screening and vacuum center domains are simply two different descriptions, one in terms of particles, the other in terms of fields, of the same effect.
\[ R[U] = \sum_{\text{contours}} c_0 + c_1 + c_2 + c_3 + \text{larger contours} \]

FIG. 7: The first few terms in the strong-coupling expansion of the lattice vacuum state \( \Psi_0[U] \), with \( R[U] = \log(\Psi_0[U]) \).

FIG. 8: How \( 1 \times 2 \) rectangles in \( R[U] \) screen an adjoint Wilson loop. The adjoint Wilson loop (in this case with extension \( 4 \times 5 \) lattice spacings) is denoted by a heavy solid line. The overlapping \( 1 \times 2 \) rectangles are indicated by (alternately) light solid and light dashed lines. The integration over lattice link variables yields a finite result, leading to a perimeter-law falloff (eq. (77)) for large adjoint loops.

that this leading correction has the same form as the leading correction to dimensional reduction that is found in the proposed vacuum state \( \Psi_0[A] \).

Denote the lattice vacuum state by \( \Psi_0[U] = \exp[R(U)] \). A strong-coupling technique for calculating \( R(U) \) in Hamiltonian lattice gauge theory was developed in ref. [2]. In this expansion \( R(U) \) is expressed as a sum over spacelike Wilson loops and products of loops on the lattice, as indicated schematically in Fig. 7. The coefficient \( c_i \) multiplying a contour constructed from (or formed by) \( n_P \) plaquettes is proportional to \( (\beta^2)^{n_P} \). For SU(2) lattice gauge theory in \( D = 2 + 1 \) dimensions, the first few coefficients \( c_0, c_1, c_2, c_3 \) of the strong-coupling series for \( R[U] \) were computed in ref. [20]. The various terms in \( R[U] \) can be expanded in a power series in the lattice spacing \( a \), and for smoothly varying fields it is found that [20]

\[ \Psi_0[U] = \exp \left[ -\frac{2}{\beta} \int d^2x \left( a\kappa_0 B^2 - a^3 \kappa_2 B(-D^2)B + \ldots \right) \right] \]

where

\[ \kappa_0 = \frac{1}{2} c_0 + 2(c_1 + c_2 + c_3) \]
\[ \kappa_2 = \frac{1}{4} c_1 \]

and coefficient \( c_0 \) is \( O(\beta^2) \), coefficients \( c_1, c_2, c_3 \) are \( O(\beta^4) \).

There are several points to note, in connection with eq. (74).

First, dimensional reduction is associated with the term proportional to \( \kappa_0 \), which receives contributions from all four terms shown in Fig. 7, but the leading correction to dimensional reduction, in the term proportional to \( \kappa_2 \), comes from the \( 1 \times 2 \) loop in \( R[U] \) proportional to \( c_1 \). This is the contour which couples \( B \) (rather than \( B^2 \)) terms in neighboring plaquettes. Secondly, it is not hard to see that the \( 1 \times 2 \) loop in \( R[U] \) gives rise to color screening. Consider evaluating a spacelike Wilson loop in the adjoint representation

\[ W_{adj}[C] = \int DU \text{Tr}[U_{adj}(C)] \Psi_0^2[U] \]

(76)

There is a non-zero contribution to the rhs of eq. (76) which comes from lining the perimeter of the adjoint loop with overlapping \( 1 \times 2 \) rectangular loops, as shown in Fig. 8, deriving from the power series expansion of \( \Psi_0^2[U] \). For a rectangular loop of perimeter \( P(C) \) this diagram gives a perimeter-law contribution

\[ \left( \frac{c_1}{2} \right)^{P(C)-4} \]

(77)

to \( W_{adj}[C] \). Thus, the same term that gives the leading correction to dimensional reduction is also responsible for the screening of adjoint loops. Finally, we note that this leading correction, proportional to \( \kappa_2 \), comes in with a negative sign relative to the \( B^2 \) term.

Now let us consider the leading correction to dimensional reduction in the proposed vacuum state \( \Psi_0[A] \) of eq. (1). The dimensional reduction term was given in eq. (35), and is quadratic in \( B_{\text{low}} \). The definition of \( B_{\text{low}} \) in eq. (34) involves a mode cutoff \( n_{\text{max}} \), chosen such that \( \Delta \lambda \equiv \lambda_{\text{max}} - \lambda_0 \ll m^2 \), and the first correction to dimensional reduction comes from terms in the vacuum wavefunctional of order \( (\lambda_n - \lambda_0)/m^2 \), with \( n < n_{\text{max}} \). These are obtained from the \( 1/m^2 \) expansion

\[ \frac{1}{\sqrt{-D^2 - \lambda_0 + m^2}} = \frac{1}{m} \left( 1 - \frac{D^2 - \lambda_0}{2m^2} + \ldots \right) \]

(78)

Taking the second term in the rhs into account, the part of the vacuum wavefunctional which is gaussian in \( B_{\text{low}} \) is

\[ \exp \left[ -\frac{1}{2m} \int d^2x \left( B_{\text{low}}B_{\text{low}} - \frac{D^2 - \lambda_0}{2m^2}B_{\text{low}} + \ldots \right) \right] \]

(79)

where the ellipsis indicates higher powers of the covariant derivative. We note the similarity of eq. (79) to the strong-coupling expression (74). In particular, there is in both cases a relative minus sign between the first and second terms.

The fact that the element responsible for color screening in \( \Psi_0[U] \) generates, in a lattice spacing expansion, the \( B(-D^2)B \) term coupling \( B \) fields in neighbouring plaquettes, is a hint

[4] Generalizing to an SU(N) theory, it is not hard to show (cf. ref. [2]) that \( c_0 \sim 1/g^2N, c_1 \sim 1/g^4N^3 \), and that the perimeter-law contribution shown in Fig. 8 is down by an overall factor of \( 1/N^2 \) relative to the leading area-law contribution, as it should be.
that it is this term which might be responsible for the color screening effect.\(^3\) If so, the presence of a very similar correction to dimensional reduction, found in \(\Psi_0[A]\), would presumably give rise to the same effect.

Of course, it is also possible that the vacuum state (1) is simply incomplete, and must be supplemented by some additional terms which are responsible for color screening. Cornwall [21] has recently conjectured that the dimensional reduction form (28) of the vacuum wavefunctional must be altered by the addition of a gauge-invariant mass term, implemented through the introduction of a group-valued auxiliary field \(\Phi(x)\), i.e.

\[
\Psi[A, \Phi] = \exp \left[ - \int d^d x \left\{ c_1 \text{Tr}[F^2_0] + c_2 \text{Tr}[\Phi^{-1} D^2 \Phi] \right\} \right]
\]

\((80)\)

The exponent of this state is stationary around center vortex solutions, suggesting a vacuum state dominated at large scales by center vortices. This would presumably solve the N-ality problem. At the moment, however, we lack any direct motivation from the Schrödinger wavefunctional equation for the existence of such a mass term.

For a discussion of the N-ality problem in the context of the KKN approach, see ref. [22].

Another type of contribution which is expected to exist in the static quark potential is the Lüscher \(-\pi(D-2)/24R\) term. We have no insight, at present, as to whether or not this term can be generated by the proposed vacuum state of eq. (1).

**IX. CONCLUSIONS**

Our proposal for the ground state of quantized Yang-Mills theory, in \(D = 2 + 1\) dimensions, has a number of virtues. Apart from agreeing with the ground state of the free theory in the appropriate limit, which is a natural starting point for any investigation of this type, we also find agreement in a highly non-trivial limit, where the Yang-Mills Schrödinger equation is truncated to the zero modes of the gauge field. In addition we find, surprisingly, that our vacuum state is amenable to numerical investigation, despite its very non-local character.

We believe that this vacuum state may provide some insight into the origins of confinement in a non-abelian theory, and the precise relationship between the mass gap and the string tension. Confinement arises here via dimensional reduction, as proposed long ago in ref. [1], and this reduction is obtained if the mass parameter \(m\) in the vacuum wavefunctional is non-zero. We have seen that \(m \neq 0\) is likely to lower the vacuum energy, in 2+1 dimensions, and this is related to the fact that in a non-abelian gauge theory the lowest eigenvalue \(\lambda_0\) of the covariant Laplacian is non-zero. The relation between \(m\) and the asymptotic string tension in 2+1 dimensions is simple, i.e. \(\sigma = 3m/4\beta\), and if the parameter \(m\) is chosen to produce the string tension known from earlier lattice Monte Carlo studies [16], then we find that the mass gap extracted from an appropriate correlator yields a value within 6% of the mass gap obtained by standard lattice Monte Carlo methods.

The most important unresolved question concerns higher representation string tensions. At issue is whether corrections to the simple dimensional reduction limit will convert Casimir scaling to N-ality dependence, as we have speculated in the previous section, or whether some additional terms (such as a gauge-invariant mass term [21]) are required. It would also be worthwhile to extend our considerations to 3+1 dimensions, and to excited-state (glueball and flux-tube) wavefunctionals. These possibilities are currently under investigation.

**Acknowledgments**

We are indebted to Dmitri Diakonov for informing us of his unpublished results, which motivated the work in section 2 of this article. We also thank Robert Leigh for helpful discussions. **APPENDIX A: 3+1 DIMENSIONS**

Although in this article we are mainly interested in the 2+1 dimensional case, it is worth pointing out that the discussion in section II can be extended to 3+1 dimensions. Define

\[
S_3 = A_1 \cdot A_1 + A_2 \cdot A_2 + A_3 \cdot A_3
\]

\(C_3 = (A_1 \times A_2) \cdot (A_1 \times A_2) + (A_2 \times A_3) \cdot (A_2 \times A_3) + (A_3 \times A_1) \cdot (A_3 \times A_1)\)

\(D_3 = [A_1 \cdot (A_2 \times A_3)]^2\)

\((A1)\)

The zero-mode Yang-Mills Hamiltonian is

\[
H = -\frac{1}{V} \frac{\partial^2}{\partial A_i^a \partial A_i^a} + \frac{g^2 V C_3}{2}\]

\((A2)\)

Again we express \(\Psi_0\) as in eq. (9), and try to solve \(H \Psi_0 = E_0 \Psi_0\) to leading order in \(V\). This time, with

\[
R_0 = \frac{g}{2} \frac{C_3}{\sqrt{S_3}}\]

\((A3)\)

we find

\[
T_0 = V \left[ \frac{\partial R_0}{\partial A_i^a} \frac{\partial R_0}{\partial A_i^a} + g^2 C_3 \right] + \frac{7 C_3^2}{4 S_3} - \frac{3 D_3}{S_3}\]

\((A4)\)

\(^3\) In fact, apart from an overall sign, the \(B(-D^2)B\) term looks like the kinetic term of a scalar field in the color adjoint representation in two Euclidean dimensions. Matter fields of that type can, of course, screen adjoint Wilson loops.
In the large volume limit, the ground-state wavefunction will only be non-negligible in the region of the “abelian valley”, where the zero-mode components $A_1, A_2, A_3$ are nearly aligned, or anti-aligned, in color space. For definiteness, take the large color component (denoted by upper-case $A$) of the color 3-vectors to all lie in the color 3-direction; i.e.

$$A_1 = \begin{bmatrix} a_1^1 \\ a_1^2 \\ a_1^3 \\ A_1^0 \end{bmatrix}, \quad A_2 = \begin{bmatrix} a_2^1 \\ a_2^2 \\ a_2^3 \\ A_2^0 \end{bmatrix}, \quad A_3 = \begin{bmatrix} a_3^1 \\ a_3^2 \\ a_3^3 \\ A_3^0 \end{bmatrix}$$ (A5)

and lower-case $a$ denotes the small components. With $a \ll A$ and $VR_0 \sim O(1)$ it follows that, in the abelian valley,

$$a \sim \frac{1}{\sqrt{gAV}}$$ (A6)

where $A$ and $a$ denote the magnitudes of the large (color 3-direction) and transverse field components, respectively. Since $C_3^2$ and $D_3$ are both $O(a^2)$, the non-zero terms contributing to $T_0$ in eq. (14) are at most of order $1/V^2$ and can be neglected. Therefore $\Psi_0 = \exp[-V R_0]$, with $R_0$ as given in eq. (A3), solves the zero-mode Yang-Mills Schrödinger equation to leading order in $V$, in the abelian valley region away from the origin ($A_1 = 0 \Rightarrow S_3 = 0$) of field space.

The generalization of eq. (1) to 3+1 dimensions is

$$\Psi_0[A] = \exp[-Q] = \exp\left[-\frac{1}{2} \int d^3x d^3y F_{ij}^a(x) \left( \frac{1}{\sqrt{-D^2 - \lambda_0 + m^2}} \right)_{xy} F_{ij}^a(y) \right]$$ (A7)

Again we consider a corner of configuration space in which only the non-zero modes make a significant contribution to the wavefunctional, and $|gA|^2 \gg m_0^2$. Then

$$(-D^2)_{xy} = g^2 \delta^2(x-y) M^{ab}$$ (A8)

as before, with

$$M^{ab} = S_3 \delta^{ab} - A_k^a A_k^b$$ (A9)

For a configuration in the abelian valley, with large components in the color 3 direction as shown in eq. (A5), we find

$$Q = \frac{1}{2} g V (A_1 \times A_j)^a (M^{-1/2})^{ab} (A_1 \times A_j)^b \approx \frac{1}{2} g V (A_1 \times A_j)^a \left( \frac{\delta^{ab}}{\sqrt{3}} - \frac{\delta^{ab} \delta^{b3}}{\sqrt{3} \sqrt{m}} \right) (A_1 \times A_j)^b$$ (A10)

Neglecting the overall coupling and volume factors, the relative orders of magnitude of each of the three contributions to $Q$ are as follows:

$$\kappa_1 = \frac{(A_1 \times A_j) \cdot (A_1 \times A_j)}{\sqrt{3}} \sim A a^2$$

$$\kappa_2 = \frac{(A_1 \times A_j)^3 (A_1 \times A_j)^3}{\sqrt{3}} \sim A^4$$

$$\kappa_3 = \frac{(A_1 \times A_j)^3 (A_1 \times A_j)^3}{m} \sim \frac{A^4}{m}$$ (A11)

Assume that $\kappa_2, \kappa_3 \ll \kappa_1$. Then we would have

$$Q = \frac{1}{2} g V C_3 \sqrt{3}$$ (A12)

and $\Psi_0[A]$, evaluated for large zero-mode gauge field configurations, would agree with the ground state solution of the zero-mode Yang-Mills Schrödinger equation in $D = 3 + 1$ dimensions, at least in the neighborhood of the abelian valley. But we have already seen that for the solution of the zero-mode equation, the magnitude $a$ of the small components is related to the magnitude $A$ of the large components according to (A6). From this it follows that the assumption $\kappa_2, \kappa_3 \ll \kappa_1$ in the abelian valley is self-consistent, and justified at large $V$ for $m \neq 0$.

**APPENDIX B: THE SPIRAL GAUGE**

Since $\Psi_0[A]$ in temporal gauge and 2+1 dimensions is gauge-invariant under two-dimensional gauge-transformations, then it is legitimate to carry out a further gauge-fixing in the two-dimensional plane when evaluating expectation values

$$\langle \Psi_0[A] | Q | \Psi_0 \rangle = \int DA Q[A] \Psi_0^2$$ (B1)

In particular, with a complete axial gauge fixing, it is possible to change variables from $A$ to field-strength $B$ without introducing any further constraints or field-dependent Jacobian factors, i.e.

$$DA_1 DA_2 \rightarrow \text{const} \times DB$$ (B2)

In higher dimensions, as Halpern has shown [3], this change of variables would be accompanied by a delta function enforcing the Bianchi constraints, but in two dimensions these constraints are absent. The simplest approach is to set $A_1(n_1, n_2) = 0$ everywhere, where $(n_1, n_2)$ are lattice site coordinates, and invert the discretized version of $B^a = \partial_1 A_2^a$ to determine $A_2$ from $B$. The problem with this is that setting $A_1 = 0$ everywhere on a finite, periodic lattice is more than a gauge choice. Gauge transformations cannot, in general, set the expectation values to zero on a closed loop, and lines parallel to the $x$-axis are closed by periodicity. Thus $A_1 = 0$ everywhere is a boundary condition, as well as a gauge choice. Although boundary conditions should be unimportant at sufficiently large lattice volumes, we would still like to keep such artificial conditions to a minimum, while retaining the simplicity of inverting $B^a = \partial_1 A_2^a$. A compromise is what we will call the “spiral gauge”, in which we set $A = 0$ (or link variables $U = I_2$) along all links in a spiral around the toroidal lattice. An example, on a $10 \times 10$
FIG. 9: The spiral gauge. Link variables on the solid lines are set equal to the identity.

lattice, is shown in Fig. 9. Along the straight sections of the spiral, parallel to the x-axis, we have

$$A_2^a(n_1 + 1, n_2) = B^a(n_1, n_2) + A_2^a(n_1, n_2)$$  \hspace{1cm} (B3)

For the bent sections, its slightly different. Referring, e.g., to the bent section in Fig. 9 starting at \(n_1 = 9, \ n_2 = 1\), we have

$$A_1^a(9, 2) = -B^a(9, 1) - A_2^a(9, 1)$$
$$A_2^a(10, 2) = B^a(9, 2) - A_1^a(9, 2)$$  \hspace{1cm} (B4)

Now suppose we start out with setting \(A_2^a(1, 1) = 0\). Applying the above rules all around the spiral we get all of the non-zero \(A\)-field variables from the \(B\)-field variables, but in order to come back to where we started, with \(A_2(1, 1) = 0\), we have to require that

$$\sum_{n_1, n_2} B^a(n_1, n_2) = 0$$  \hspace{1cm} (B5)

To enforce this condition, we first generate the \(B\)-field without constraint, compute the sum

$$S^a = \sum_{n_1, n_2} B^a(n_1, n_2)$$  \hspace{1cm} (B6)

and then make the readjustment

$$B^a(n_1, n_2) \rightarrow B^a(n_1, n_2) - \frac{S^a}{L^2}$$  \hspace{1cm} (B7)

So we have done two things beyond just fixing the gauge. First, the \(A\)-field has been set to zero on a single closed spiral around the toroidal lattice. Secondly, by setting in addition \(A_2(1, 1) = 0\), we have imposed a restriction that the \(B\)-field on the lattice averages to zero in any given configuration. These conditions have been imposed for calculational simplicity; they are not as drastic as setting \(A_1 = 0\) on all links (which sets all Polyakov lines in the \(x\)-direction equal to unity), and ought to be harmless at sufficiently large lattice volumes.
