Abstract

We calculate the new physics contributions to the rare semileptonic decay $B \rightarrow X_s l^+ l^-$ ($l = e, \mu$) induced by the charged-Higgs loop diagrams appeared in the top quark two-Higgs doublet model (T2HDM). Within the considered parameter space, we found that (a) the effective Wilson coefficients $\tilde{C}_{\gamma}^{\text{eff}}(m_b)$ ($i = 7\gamma, 9V$ and $10A$) in the T2HDM are always standard model like; (b) the new physics contributions to $\tilde{C}_{\gamma}^{\text{eff}}$ and $\tilde{C}_{9V}^{\text{eff}}$ can be significant in magnitude, but they tend to cancel each other; and (c) the T2HDM predictions for $Br(B \rightarrow X_s l^+ l^-)$ agree well with the measured value within one standard deviation.

I. INTRODUCTION

Flavor changing neutral current (FCNC) $b \to s$ processes are forbidden at the tree level in the Standard Model (SM). They proceed at a low rate via penguin or box diagrams. If additional diagrams with non-SM particles contribute to such a decay, their amplitudes will interfere with the SM amplitudes and thereby modify the rate as well as other properties. This feature makes FCNC processes an ideal place to search for new physics.

In the past decade, the data of $B \to X_s \gamma$ decay has served as one of the most important constraints for various new physics models beyond the SM. At present, the world average, $Br(B \to X_s \gamma) = (3.55 \pm 0.26) \times 10^{-4}$, agrees very well with the standard model prediction at next-next-to-leading order (NNLO). The magnitude of the Wilson coefficient $C_7(\mu_b)$ is therefore strongly constrained by the precision data of $B \to X_s \gamma$, but its sign is still to be determined through the measurement of $B \to X_s l^+ l^-$ decay.

In Ref. [3], the authors studied $B \to X_s l^+ l^-$ decay and found that the recent experimental data of $Br(B \to X_s l^+ l^-)$ prefer a SM-like $C_7(\mu_b)$.

In fact, the semileptonic decays $B \to X_s l^+ l^-$ ($l = e, \mu$) have been extensively investigated, for example, in the SM [4, 5], the two-Higgs doublet models (2HDM) [6] or the supersymmetric models [7, 8]. Our goal in the present work is to calculate the new physics contributions to the branching ratio of $B \to X_s \gamma$ and $B \to X_s l^+ l^-$ decays induced by the charged Higgs loop diagrams in the top-quark two-Higgs-doublet model (T2HDM) [9, 10, 11], and compare the theoretical predictions in the T2HDM with currently available data.

The outline of the paper is as follows. In section II, we give a brief review for the top-quark two-Higgs-doublet model and we calculate the new penguin diagrams induced by new particles and extract out the new physics parts of the Wilson coefficients or some basic functions in the T2HDM. In section III, we present the numerical results of the branching ratios of $B \to X_s l^+ l^-$ decay in the SM and the T2HDM, and make phenomenological analysis. The conclusions are included in the final section.

II. THEORETICAL FRAMEWORK

A. Outline of the top quark two-Higgs-doublet model

The specific model considered here is the top quark two-Higgs-doublet model (T2HDM) proposed in Ref. [9] and studied in Refs. [10, 11], which is also a special case of the 2HDM of type III [12]. In this model, the large mass of the top quark arises naturally in the extension of the SM since the top quark is the only fermion receiving its mass from the vacuum expectation value (VEV) of the second Higgs doublet. All the other fermions receive their masses from the VEV of the first Higgs doublet.

Let us now briefly recapitulate some important features of the model of Ref. [9]. Consider the Yukawa Lagrangian of the form:

$$L_Y = -T_L \phi_i E l_R - Q_L \phi_i F d_R - \bar{Q}_L \phi_i \bar{G} G 1^{(1)} u_R - \bar{Q}_L \phi_2 \bar{G} G 1^{(2)} u_R + H.c. \quad (1)$$

where $Q_L$ and $L_L$ are 3-vector of the left-handed quark and lepton doublets, respectively; $\phi_i (i = 1, 2)$ are the two Higgs doublets with $\phi_i = i \tau_2 \phi_i^*$; and $E, F, G$ are the $3 \times 3$ matrices
in the generation space and give masses respectively to the charge d leptons, the down and up type quarks; \( \mathbf{1}^{(1)} \equiv \text{diag}(1, 1, 0); \mathbf{1}^{(2)} \equiv \text{diag}(0, 0, 1) \) are the two orthogonal projection operators onto the first two and the third families respectively. The top quark is assigned a special status by coupling it to one Higgs doublet that gets a large VEV, whereas all the other quarks are coupled only to the other Higgs doublet whose VEV is much smaller. Consequently, if one sets the VEVs of \( \phi_1 \) and \( \phi_2 \) to be \( v_1/\sqrt{2} \) and \( v_2 e^{i\theta}/\sqrt{2} \), respectively, the ratio of two Higgs VEVs, \( \tan\beta = v_2/v_1 \), is required to be relatively large.

The Yukawa couplings involving the charged-Higgs bosons are of the form \[ L_C^Y = g\sqrt{2} M_W \left\{ -\overline{u}_L V d_R \left[ G^+ - \tan\beta H^+ \right] + \overline{u}_R \Sigma^\dagger V d_L \left[ G^+ - \tan\beta H^+ \right] \right\} + \overline{u}_R \Sigma^\dagger V d_L \left[ \tan\beta + \cot\beta \right] H^+ \right\} + \text{h.c.} \] (2)

where \( G^\pm \) and \( H^\pm \) denote the would-be Goldstone bosons and the physical charged Higgs bosons, respectively. Here \( M_U \) and \( M_D \) are the diagonal up- and down-type mass matrices, \( V \) is the usual CKM matrix and \( \Sigma \equiv M_U U_R^\dagger \mathbf{1}^{(2)} U_R \). \( U_R \) is the unitary matrix which diagonalizes the right-handed up-type quarks and has the following form:

\[
U_R = \begin{pmatrix}
\cos\phi & -\sin\phi & 0 \\
\sin\phi & \cos\phi & 0 \\
0 & 0 & 1
\end{pmatrix} \times \begin{pmatrix}
1 & 0 & 0 \\
0 & \sqrt{1 - |\epsilon_{ct}\xi|^2} & -\epsilon_{ct}\xi^* \\
0 & \epsilon_{ct}\xi & \sqrt{1 - |\epsilon_{ct}\xi|^2}
\end{pmatrix}. \tag{3}
\]

where \( \epsilon_{ct} \equiv m_c/m_t, \xi = |\xi| e^{i\delta} \) is a complex number of order unity, and the phase \( \delta \) in \( \xi \) is a new CP violating phase. Inserting Eq. (3) into the definition of \( \Sigma \) yields

\[
\Sigma = \begin{pmatrix}
0 & 0 & 0 \\
0 & \sqrt{m_c^2 |\xi|^2} & -\epsilon_{ct}\xi^* \\
0 & \epsilon_{ct}\xi & \sqrt{m_c^2 |\xi|^2}
\end{pmatrix} \begin{pmatrix}
0 \\
m_c \epsilon_{ct} \xi \sqrt{1 - |\epsilon_{ct}\xi|^2} \\
m_t \left( 1 - |\epsilon_{ct}\xi|^2 \right)
\end{pmatrix}. \tag{4}
\]

In the following sections, we will calculate the charged Higgs contributions to the rare decay \( B \to X_s l^+ l^- \) in the top quark two-Higgs-doublet model.

**B. Effective Hamiltonian for \( B \to X_s l^+ l^- \) in the SM**

In the framework of the SM, the effective hamiltonian inducing the transition \( b \to sl^+ l^- \) at the scale \( \mu \) can be written as follows:

\[
\mathcal{H} = -\frac{4 G_F}{\sqrt{2}} V^*_{ts} V_{tb} \sum_{i=1}^{10} C_i(\mu) Q_i(\mu), \tag{5}
\]

\[ \text{where} \quad C_i(\mu) = \left( \frac{\alpha_i}{\pi} \right) \frac{1}{\mu^2} \int_{\mu^2}^{\Lambda^2} \frac{d^2 q}{(2\pi)^2} \frac{1}{q^2 m_b^2} \()^{1/2} \right\}, \]
where $G_F$ is the coupling constant, and $V_{tb}V_{tb}^*$ is the Cabibbo-Kobayashi-Maskawa (CKM) factor \cite{13}. The operators can be chosen as Ref. \cite{3}:

\begin{align}
Q_1 &= (\bar{s}_L \gamma_\mu T^a c_L)(\bar{c}_L \gamma^\mu T^a b_L), \\
Q_3 &= (\bar{s}_L \gamma_\mu b_L) \sum_q (\bar{q}_\gamma^\mu q), \\
Q_5 &= (\bar{s}_L \gamma_{\mu_1} \gamma_{\mu_2} \gamma_{\mu_3} b_L) \sum_q (\bar{q}_\gamma^\mu \gamma^\mu_{\mu_2} \gamma^\mu_{\mu_3} q), \\
Q_7 &= \frac{e}{g_s^2} m_b (\bar{s}_L \sigma^{\mu \nu} b_R) F_{\mu \nu}, \\
Q_9 &= \frac{e^2}{g_s^2} (\bar{s}_L \gamma_{\mu} b_L) \sum_\ell (\bar{\ell}_\gamma^\mu \ell), \\
Q_{10} &= \frac{e^2}{g_s^2} (\bar{s}_L \gamma_{\mu} b_L) \sum_\ell (\bar{\ell}_\mu \gamma_\gamma \gamma_\ell), \tag{6}
\end{align}

where $Q_{1,2}$ are the current-current operators, $Q_{3-6}$ the QCD penguin operators, $Q_{7,8}$ “magnetic penguin” operators, and $Q_{9,10}$ semileptonic electroweak penguin operators. $T^a (a = 1, ..., 8)$ stands for $SU(3)_c$ generators, $L, R \equiv (1 \mp \gamma_5)/2$ by definition. The sum over $q$ runs over the quark fields that are active at the scale $\mu = \mathcal{O}(m_b)$, i.e., $q \in \{u, d, s, c, b\}$. We work in the approximation where the combination $(V_{us}^* V_{ub})$ of the Cabibbo-Kobayashi-Maskawa (CKM) matrix elements is neglected. We do not separate top-quark and charm-quark contributions and will give the results in the summed form.

To calculate the semileptonic B meson decays at next-to-leading order in $\alpha_s$, we should determinate the Wilson coefficient $C_i(M_W)$ through matching of the full theory onto the five-quark low energy effective theory where the $W^\pm$ gauge boson, top quark and the new particles of T2HDM heavier than $M_W$ are integrated out, and run the Wilson coefficients down to the low energy scale $\mu \sim \mathcal{O}(m_b)$ by using the QCD renormalization group equations. The corresponding Wilson coefficients in SM can be found, for example, in Refs. \cite{14, 15}.

C. New physics contributions

In the framework of the SM, the semileptonic $B \to X_s l^+ l^-$ ($l = e^-, \mu^-$) decays proceed through loop diagrams and are of forth order in the weak coupling. The dominant contributions to this decay come from the $W$ box and $Z$ penguin diagrams. The corresponding one-loop diagrams in the SM were evaluated long time ago and can be found in Refs. \cite{4, 16}. The calculations at the next-next-to-leading order (NNLO) are also available now.

In the T2HDM considered here, besides the SM diagrams with a W-gauge boson and an up quark in the loop, the $B \to X_s l^+ l^-$ decays can also proceed via the new diagrams involving the charged-Higgs boson exchanges, as illustrated by Fig. \ref{fig:diagram}. In order to determine the new physics contributions to the relevant Wilson coefficients $C_{7\gamma}, C_{8g}, C_{9V}$, and $C_{10A}$ at the $M_W$ scale, we need to calculate the corresponding Feynman diagrams.

The new physics parts of the Wilson coefficients $C_{7\gamma}$ and $C_{8g}$ have been calculated in Refs. \cite{10, 11} and confirmed by our independent calculation. In the naive dimensional
FIG. 1: The typical Feynman diagrams for the decay $B \rightarrow X_s l^+ l^-$ in the T2HDM. The internal solid and dashed lines denote the propagators of upper quarks (u,c,t) and charged Higgs boson, respectively.

regularization (NDR) scheme, they are of the form

$$C_{7\gamma}(M_W) = \sum_{i=c,t} \kappa^{is} \left[ -\tan^2 \beta + \frac{1}{m_i V_{is}^*} (\Sigma^T V_{is}) (\tan^2 \beta + 1) \right]$$

$$\cdot \left\{ B(y_i) + \frac{1}{6} A(y_i) \left[ -1 + \frac{1}{m_i V_{ib}} (\Sigma^T V_{ib}) (\cot^2 \beta + 1) \right] \right\},$$

(7)

$$C_{8g}(M_W) = \sum_{i=c,t} \kappa^{is} \left[ -\tan^2 \beta + \frac{1}{m_i V_{is}^*} (\Sigma^T V_{is}) (\tan^2 \beta + 1) \right]$$

$$\cdot \left\{ E(y_i) + \frac{1}{6} F(y_i) \left[ -1 + \frac{1}{m_i V_{ib}} (\Sigma^T V_{ib}) (\cot^2 \beta + 1) \right] \right\},$$

(8)

with the Inami-Lim functions

$$A(y) = \frac{7y - 5y^2 - 8y^3}{12(1 - y)^3} + \frac{2y^2 - 3y^3}{2(1 - y)^4} \ln[y],$$

$$B(y) = \frac{-3y + 5y^2}{12(1 - y)^2} - \frac{2y - 3y^2}{6(1 - y)^3} \ln[y],$$

$$E(y) = \frac{-3y + y^2}{4(1 - y)^2} - \frac{y}{2(1 - y)^3} \ln[y],$$

$$F(y) = \frac{2y + 5y^2 - y^3}{4(1 - y)^3} + \frac{3y^2}{2(1 - y)^4} \ln[y],$$

(9)

where $\kappa^{is} = -V_{ib} V_{is}^*/(V_{tb} V_{ts}^*)$, $y_i = (m_i/m_H)^2$.

As for the Wilson coefficients $C_{9V}$, and $C_{10A}$ at the $M_W$ scale, we found the new physics
parts after calculating analytically the Feynman diagrams as shown in Fig. 1

\[ C_{9\nu}(M_W) = \frac{1}{\sin^2 \theta_W} [C_{0}^{NP} - B_{0}^{NP}] - [D_{0}^{NP} + 4C_{0}^{NP}], \]  
\[ C_{10\lambda}(M_W) = -\frac{1}{\sin^2 \theta_W} [C_{0}^{NP} - B_{0}^{NP}], \]  

where

\[ B_{0}^{NP} = -\frac{m_{l} m_{b} \tan^2 \beta}{8 M_{W}^2} B_{+}(x_{H^+}, x_{t}), \]  
\[ C_{0}^{NP} = \sum_{i=c, t} \kappa_{is} \frac{m^2_{i}}{8 M_{W}^2} \left\{ \left[ C'_{01}(y_{i}) - \frac{4 m_{b}^2}{3 m^2_{i}} \sin^2 \theta_W C'_{11}(y_{i}) \right] \right. \]  
\[ \cdot \left[ -\tan^2 \beta + \frac{1}{m_{i} V_{is}^*} (\Sigma^T V^*)_{i s} (\tan^2 \beta + 1) \right] \left[ -1 + \frac{1}{m_{i} V_{i b}} (\Sigma^\dagger V)_{i b} (\cot^2 \beta + 1) \right] \]  
\[ \left. + \frac{m^2_{b}}{m^2_{i}} \left[ (1 - \frac{4}{3} \sin^2 \theta_W) C'_{01}(y_{i}) - C'_{11}(y_{i}) \right] \right\}, \]  
\[ D_{0}^{NP} = \sum_{i=c, t} \kappa_{is} \frac{2 H(y_{i})}{3} \left[ -\tan^2 \beta + \frac{1}{m_{i} V_{is}^*} (\Sigma^T V^*)_{i s} (\tan^2 \beta + 1) \right] \]  
\[ \cdot \left[ -1 + \frac{1}{m_{i} V_{i b}} (\Sigma^\dagger V)_{i b} (\cot^2 \beta + 1) \right], \]  

with

\[ B_{+}(x, z) = \frac{z}{x - z} \left[ \frac{\ln[z]}{z - 1} - \frac{\ln[x]}{x - 1} \right], \]  
\[ H(y) = \frac{38 y - 79 y^2 + 47 y^3}{72(1 - y)^3} + \frac{4 y - 6 y^2 + 3 y^4}{12(1 - y)^4} \ln[y], \]  
\[ C_{01}'(y) = \frac{y}{1 - y} + \frac{y}{(1 - y)^2} \ln[y], \]  
\[ C_{11}'(y) = \frac{3 y - y^2}{4(1 - y)^2} + \frac{y}{2(1 - y)^3} \ln[y]. \]  

where \( y_{i} = m^2_{i}/m^2_{H^*}, x_{H^+} = m^2_{H^*}/M_{W}^2, \) and \( x_{t} = m^2_{t}/M_{W}^2. \) \( V \) is the CKM matrix, and the matrix \( \Sigma \) has been given in Eq. (4). The contributions from Fig. 2a and the Fig. 3 when the internal \( W \) and charged-Higgs lines exchange their position are strongly suppressed by a factor of \((m_{l}/m_{H^*})^{2} (m_{l} = m_{e}, m_{\mu}) \) or \( m_{s}/m_{b}, \) and therefore have been neglected.
D. The differential decay rate

Within the Standard Model, the differential decay rate for the decay $B \to X_s l^+ l^-$ in the NNLO approximation can be written as [3, 17]

\[
R(\hat{s}) \equiv \frac{d \Gamma(b \to s l^+ l^-)}{\Gamma(b \to c e \nu)} = \frac{\alpha_{em}^2}{4\pi^2} \left| V_{ts}^* V_{tb} \right|^2 \frac{(1-\hat{s})^2}{f(z) k(z)} \left[ (1+2\hat{s}) \left( |\tilde{C}_{9V}^{\text{eff}}(\hat{s})|^2 + |\tilde{C}_{10A}^{\text{eff}}(\hat{s})|^2 \right) \right] + 4 \left( 1 + \frac{2}{\hat{s}} \right) |\tilde{C}_{7G}^{\text{eff}}|^2 + 12 \text{Re} \left[ \tilde{C}_{7G}^{\text{eff}} \left( \tilde{C}_{9V}^{\text{eff}}(\hat{s}) \right)^* \right],
\]

(16)

where

\[
\tilde{C}_k^{\text{eff}} = -\tilde{C}_k^{\text{eff}} + \frac{V_{us}^* V_{ub}}{V_{ts}^* V_{tb}} \delta_{k9} \Delta C_k^{\text{eff}}
\]

(17)

that are related to the evolved coefficients $C_k(\mu_b)$ as follows:

\[
\tilde{C}_{7G}^{\text{eff}} = \frac{4\pi}{\alpha_s(\mu_b)} C_7(\mu_b) - \frac{1}{3} C_3(\mu_b) - \frac{4}{9} C_4(\mu_b) - \frac{20}{3} C_5(\mu_b) - \frac{80}{9} C_6(\mu_b),
\]

(18)

\[
\tilde{C}_{9V}^{\text{eff}}(\hat{s}) = 4 C_9(\mu_b) \left( \frac{\pi}{\alpha_s(\mu_b)} + \omega(\hat{s}) \right) + \sum_{i=1}^{6} C_i(\mu_b) C_i^{(0)} \ln \frac{m_b}{\mu_b}
\]

\[+ h \left( \frac{m_c^2}{m_b^2}, \hat{s} \right) \left[ \frac{4}{3} C_1(\mu_b) + 3 C_2(\mu_b) + 6 C_3^Q(\mu_b) + 60 C_5^Q(\mu_b) \right] + h(1, \hat{s}) \left( \frac{7}{2} C_3(\mu_b) - \frac{2}{3} C_4(\mu_b) - 38 C_5(\mu_b) - \frac{32}{3} C_6(\mu_b) \right)
\]

\[+ h(0, \hat{s}) \left( \frac{1}{3} C_3(\mu_b) - \frac{2}{3} C_4(\mu_b) - 8 C_5(\mu_b) - \frac{32}{3} C_6(\mu_b) \right)
\]

\[+ \frac{4}{3} C_3(\mu_b) + \frac{64}{9} C_5(\mu_b) + \frac{64}{27} C_6(\mu_b),
\]

(19)

\[
\tilde{C}_{10A}^{\text{eff}}(\hat{s}) = 4 C_{10}(\mu_b) \left( \frac{\pi}{\alpha_s(\mu_b)} + \omega(\hat{s}) \right),
\]

(20)

\[
\Delta C_{9V}^{\text{eff}} = \left[ h(0, \hat{s}) - h \left( \frac{m_c^2}{m_b^2}, \hat{s} \right) \right] \left( \frac{4}{3} C_1(\mu_b) + C_2(\mu_b) \right),
\]

(21)

with

\[
h(z, \hat{s}) = -\frac{4}{9} \ln z + \frac{8}{27} + \frac{4}{9} x - \frac{2}{9} (2 + x) \sqrt{1 - x} \left\{ \ln \left[ \frac{\sqrt{1 - x} + 1}{x - 1} \right] - i\pi, \quad \text{for } x \equiv 4z/\hat{s} < 1,
\]

\[\frac{4}{9} \tan^{-1}(1/\sqrt{x - 1}), \quad \text{for } x \equiv 4z/\hat{s} > 1,
\]

(22)

\[
h(0, \hat{s}) = \frac{8}{27} - \frac{4}{9} (\ln \hat{s} - i\pi),
\]

\[
\omega(\hat{s}) = -\frac{4}{3} \ln(1 + \hat{s}) - \frac{2}{3} \ln(1 - \hat{s}) \ln \hat{s} - \frac{2}{9} \pi^2 - \frac{5}{3(1 + 2\hat{s})} \ln(1 - \hat{s}) + \frac{8\hat{s}(1 + \hat{s})(1 - 2\hat{s})}{3(1 - \hat{s})^2(1 + 2\hat{s})} \ln \hat{s} + \frac{5 + 9\hat{s} - 6\hat{s}^2}{6(1 - \hat{s})(1 + 2\hat{s})},
\]

(24)
and
\begin{equation}
\kappa(z) \simeq 1 - \frac{2\alpha_s(\mu)}{3\pi} \left[ \left( \frac{\pi^2}{3} - \frac{31}{4} \right) (1 - z)^2 + \frac{3}{2} \right],
\end{equation}

here \( \hat{s} = (p_+ + p_-)^2/m^2 = m_1^2/m_0^2 \), \( z = m_c/m_b \), \( f(z) \) and \( \kappa(z) \) are the phase-factor and single gluon QCD correction to the \( b \to c e \bar{\nu} \) decay, respectively.

In Refs. [17], the Wilson coefficients have been expanded perturbatively as follows
\begin{equation}
C_i = C_i^{(0)} + \frac{g_5^2}{(4\pi)^2} C_i^{(1)} + \frac{g_5^4}{(4\pi)^4} C_i^{(2)} + O(g^6).
\end{equation}

For the standard model parts of the Wilson coefficients \( C_i^{(0)}, C_i^{(1)} \) and \( C_i^{(2)} \), the explicit expressions as given in Refs. [5, 17] will be used in our numerical calculation. For the new physics part, only \( C_i^{(1)NP}(M_W) \) are known at present, as given explicitly in Eqs. (7,8,10), and will be included in numerical calculations.

### III. NUMERICAL RESULT

In this section, we first give the input parameters needed in numerical calculations, and then present the numerical results and make some theoretical analysis.

#### A. input parameters

In numerical calculations we will use the following input parameters (all masses are in GeV) [18]:
\begin{align*}
M_W &= 80.425, \quad G_F = 1.16639 \times 10^{-5}\text{GeV}^{-2}, \quad \alpha_{em} = 1/128, \\
m_c &= 1.4, \quad m_b = 4.8 \pm 0.2, \quad m_t = 173.8 \pm 5, \quad \Lambda_{\overline{\text{MS}}}^{(5)} = 0.225, \\
A &= 0.853, \quad \lambda = 0.2200, \quad \rho = 0.20 \pm 0.09, \quad \eta = 0.33 \pm 0.05, \\
\sin^2 \theta_W &= 0.23124, \quad Br(B \to X_c e \bar{\nu}) = 0.1061,
\end{align*}

where the parameter \( A, \lambda, \rho \) and \( \eta \) are Wolfenstein parameters of the CKM mixing matrix. For the strong coupling constant \( \alpha_s(\mu) \) we use the two-loop expression,
\begin{equation}
\alpha_s(\mu) = \frac{4\pi}{\beta_0 \ln(\mu^2/\Lambda_{\overline{\text{MS}}}^2)} \left[ 1 - \frac{\beta_1}{\beta_0^2} \cdot \frac{\ln(\mu^2/\Lambda_{\overline{\text{MS}}}^2)}{\ln(\mu^2/\Lambda_{\overline{\text{MS}}}^2)} \right],
\end{equation}

with
\begin{equation}
\beta_0 = \frac{33 - 2f}{3}, \quad \beta_1 = 72 - 10f - 8f/3
\end{equation}

where the \( f \) is the number of quark flavors and the term \( \overline{\text{MS}} \) denotes the modified subtraction scheme.
B. \( B \to X_s \gamma \) decay

There are four free parameters \( m_H, \tan \beta, |\xi| \) and a new CP-violating phase \( \delta \) in the T2HDM. We fix \(|\xi| = 1\) throughout the paper and consider other three as variable parameters to be constrained by precise measurements, such as the date of \( Br( B \to X_s \gamma) \).

In Ref. [19], the branching ratio \( Br(B \to X_s \gamma) \) have been calculated in both the SM and the T2HDM. Using the formulas as given in Appendix A and taking the range of

\[
2.77 \times 10^{-4} \leq Br(B \to X_s \gamma) \leq 4.33 \times 10^{-4}
\]

as the experimentally allowed region at 3\( \sigma \) level [1], one can read off the lower limit on the mass of charged-Higgs boson \( m_H \) directly from Fig. 2:

\[
m_H \geq 300 \text{GeV},
\]

for fixed \( \tan \beta = 30 \) and \( \delta = 0^\circ \). It is easy to see from Fig. 2 that (a) a light charged Higgs boson with a mass less than 200 GeV is excluded by the data of \( B \to X_s \gamma \) decay at 3\( \sigma \) level; and (b) a charged-Higgs boson with a mass heavier than 300 GeV is still allowed by the same data.

![FIG. 2: The \( m_H \) dependence of \( Br(B \to X_s \gamma) \) in the T2HDM for \( \delta = 0^\circ \), and for \( \tan \beta = 10, 20, 30, 40 \) and 50 respectively. The band between two horizontal dash dot lines shows data as specified in Eq. (31). The solid horizontal line shows the central value of the SM prediction.](image)

As shown in the contour plot Fig. 3, the region between the short-dashed and solid curves is still allowed by the data of \( B \to X_s \gamma \) as given in Eq. (31) for fixed value of \( \delta = 0^\circ \). On the other hand, by assuming \( \tan \beta = 30 \) and \( m_H = 400 \text{ GeV} \), one finds a strong constraint on the phase \( \delta \): \( \delta < 44^\circ \).
C. $B \rightarrow X_s l^+ l^-$ decay

The branching ratio of $B \rightarrow X_s l^+ l^-$ ($l = e, \mu$) has been recently measured by BaBar and Belle Collaborations\cite{20, 21}. In the low-$q^2$ region\footnote{The low-$q^2$ region is the region with $1 \text{GeV}^2 \leq m_{ll}^2 \equiv q^2 \leq 6 \text{GeV}^2$.}, the average of BaBar and Belle’s measurements is\cite{3}

$$Br(B \rightarrow X_s l^+ l^-) = (1.60 \pm 0.51) \times 10^{-6}. \quad (33)$$

Theoretically, the integrated branching ratio can be written as\cite{17}

$$Br_{ll} = Br(B \rightarrow X_c l \nu) \int_{\hat{s}_a}^{\hat{s}_b} R(\hat{s}), \quad (34)$$

where $\hat{s} = q^2/m_b^2$ with $\hat{s}_a = 1/m_b^2$ and $\hat{s}_b = 6/m_b^2$, and the differential decay rate $R(\hat{s})$ has been defined in Eq. (16). The SM prediction after integrating over the low-$q^2$ region reads

$$Br(B \rightarrow X_s l^+ l^-) = (1.58 \pm 0.08|m_t| \pm 0.07|\mu_b| \pm 0.04|c_{KM}| \pm 0.06|m_b| + 0.18|\mu_w|) \times 10^{-6}$$

$$= (1.58 \pm 0.13 + 0.18|\mu_w|) \times 10^{-6}. \quad (35)$$

where the errors correspond to the uncertainty of input parameters of $m_t$, $A$, $\rho$, $\eta$ and $m_b$ as shown in Eq. (28), and for $m_b/2 \leq \mu_b \leq 2m_b$. The last error refers to the choice of $\mu_W = 120$ GeV, instead of $\mu_W = M_W$. Since we here focus on the new physics
TABLE I: The effective Wilson coefficients and the interference term \(12Re[\tilde{C}_{7\gamma}^{\text{eff}}(\tilde{C}_{9\gamma}^{\text{eff}})^*]\) for fixed \(\hat{s} = q^2/m_b^2 = 0.2\), the branching ratio integrated over the low-\(q^2\) region in units \(10^{-6}\) in the SM and the T2HDM for \(m_H = 300\), \(\tan \beta = 10, 30, 50\) and \(\delta = 0^\circ\) (a), \(30^\circ\) (b) and \(60^\circ\) (c). Only the central values are shown here.

contributions to the branching ratios of \(B \rightarrow X_s l^+ l^-\) decay, we will take \(\mu_W = M_W\) in the following without further specification.

Now we consider the new physics contributions. When the new physics parts of the Wilson coefficients \(C_i^{(1)(M_W)}\) for \(i = 7\gamma, 8\gamma, 9\gamma\) and \(10\gamma\) are taken into account, the values of the effective Wilson coefficients appeared in Eq. (16) and the theoretical predictions of the branching ratio will be changed accordingly, as listed in Table I for \(\tan \beta = 10, 30, 50, m_H = 300\) \(\text{GeV}\) and \(\delta = 0^\circ, 30^\circ\) and \(60^\circ\).

In Figs. 4 and 5 in order to show more details of the \(m_H\) and \(\tan \beta\) dependence, we draw the real part of the effective Wilson coefficients \(\tilde{C}_{7\gamma}^{\text{eff}}(m_b)\) and \(\tilde{C}_{9\gamma}^{\text{eff}}(m_b)\) for fixed \(\hat{s} = q^2/m_b^2 = 0.2\) and \(\delta = 0^\circ\). Within the considered parameter space of the T2HDM, it is easy to see from the numerical results in Table I and illustrated explicitly by Figs. 4 and 5 that

(i) The effective Wilson coefficient \(\tilde{C}_{7\gamma}^{\text{eff}}(m_b)\) is always SM-like. This feature can be seen explicitly in Fig. 4, where the \(m_H\)-dependence of the real part of \(\tilde{C}_{7\gamma}^{\text{eff}}(m_b)\) is shown for \(\delta = 0^\circ\), \(\tan \beta = 10, 30, 50\) and \(200\text{GeV} \leq m_H \leq 1000\text{GeV}\). The imaginary part of \(\tilde{C}_{7\gamma}^{\text{eff}}(m_b)\) is generally small.

(ii) The effective Wilson coefficient \(\tilde{C}_{9\gamma}^{\text{eff}}(m_b)\) is also SM-like. The imaginary part of \(\tilde{C}_{9\gamma}^{\text{eff}}(m_b)\) is also generally small.

(iii) The new physics contribution to \(\tilde{C}_{10\gamma}^{\text{eff}}\) is very small in size, less than 1% of its standard model counterpart, and therefore can be neglected safely.

(iv) The new physics contributions to \(\tilde{C}_{7\gamma}^{\text{eff}}\) and \(\tilde{C}_{9\gamma}^{\text{eff}}\) can be significant in magnitude respectively for large \(\tan \beta\), large \(\delta\) and lighter charged-Higgs boson, as can be seen from the numerical results in Table I and illustrated explicitly by Figs. 4 and 5. But
FIG. 4: The $m_H$ dependence of the real part of the effective Wilson coefficient $\tilde{C}_{7\gamma}^{\text{eff}}(m_b)$ in the SM (solid line) and T2HDM for $\delta = 0^\circ$, and $\tan \beta = 10$ (dots curve), 30 (dot-dashed curve) and 50 (dashed curve), respectively.

FIG. 5: The $m_H$ dependence of the real part of the effective Wilson coefficient $\tilde{C}_{9V}^{\text{eff}}(m_b)$ in the SM (solid line) and T2HDM for $\hat{s} = 0.2$, $\delta = 0^\circ$, and $\tan \beta = 10$ (dots curve), 30 (dot-dashed curve) and 50 (dashed curve), respectively.

they tend to cancel each other and finally lead to a small change to the prediction for the branching ratio under study.

It is worth noting that both the real and imaginary parts of effective Wilson coefficients are taken into account in our calculation of the branching ratio.

As shown in Eq. (16), the differential decay rate depends on the summation of three
FIG. 6: The $m_H$ dependence of the branching ratio of $B \to X_s l^+ l^-$ in the SM and T2HDM for $\delta = 0^\circ$, and $\tan \beta = 30$. The contributions from the term-1, term-2, interference term and their summation are shown by the dot-dashed, dashed, short-dashed and solid curve, respectively. The horizontal band between two dots line shows the data: $Br(B \to X_s l^+ l^-) = (1.60 \pm 0.51) \times 10^{-6}$, while the solid line refers to the central value of SM prediction: $Br(B \to X_s l^+ l^-) = 1.58 \times 10^{-6}$.

terms:

\begin{align*}
Term - 1 : & \quad (1 + 2\hat{s}) \left(\left|\tilde{C}^{eff}_{9V}(\hat{s})\right|^2 + \left|\tilde{C}^{eff}_{10A}(\hat{s})\right|^2\right), \\
Term - 2 : & \quad 4 \left(1 + \frac{2}{\hat{s}}\right) \left|\tilde{C}^{eff}_{7\gamma}\right|^2, \\
Term - 3 : & \quad 12 \text{Re} \left[\tilde{C}^{eff}_{7\gamma} \left(\tilde{C}^{eff}_{9V}(\hat{s})\right)^*\right],
\end{align*}

where the third term is the interference term, which has opposite sign compared to first two terms. From Fig. 6, one can see easily that

(i) After the inclusion of new physics contributions in T2HDM, the signs of three terms remain unchanged.

(ii) The new physics contributions to these three terms are indeed tend to cancel each other and result in a summation (solid curve in Fig. 6) which becomes closer to the SM prediction (solid line in Fig. 6) when $m_H$ becoming larger. The theoretical predictions for the branching ratio in the SM and T2HDM agree well for the whole range of $m_H$ considered here. They are also in good agreement with the data within one standard deviation.

Analogous to Fig. 6, the Figs. 7 and 8 show the $\tan \beta$ and $\delta$ dependence of the branching ratio $Br(B \to X_s l^+ l^-)$, respectively. Here, the cancelation of new physics contributions to different terms occurs and leaves the summation, the theoretical prediction in
FIG. 7: The same as Fig. 6 but shows the tan β dependence of the branching ratio of $B \to X_s l^+ l^-$ in the SM and T2HDM for $\delta = 0^\circ$ and $m_H = 300$ GeV.

FIG. 8: The same as Fig. 6 but shows the $\delta$ dependence of the branching ratio of $B \to X_s l^+ l^-$ in the SM and T2HDM for $\tan \beta = 30$ and $m_H = 300$ GeV.

the T2HDM, in good agreement with the SM prediction as well as the measured value within one standard deviation. From Fig. 7 one can also see that a $\tan \beta$ smaller than 40 is preferred by current data.
IV. SUMMARY

In this paper, we calculate the new physics contributions to the branching ratio of $B \rightarrow X_s \gamma$ and $B \rightarrow X_s l^+ l^-$ decays induced by the charged Higgs loop diagrams in the top-quark two-Higgs-doublet model, and compare the theoretical predictions in the T2HDM with currently available data.

In Sec. II, we firstly present a brief review about the basic structure of the top-quark two-Higgs-doublet model, and then evaluate analytically the new Feynman diagrams induced by the charged Higgs $H^\pm$ exchanges and extract the new physics parts of the Wilson coefficients $C_{7\gamma}^{NP}(\mu_W)$, $C_{8g}^{NP}(\mu_W)$, $C_{9V}^{NP}(\mu_W)$ and $C_{10A}^{NP}(\mu_W)$ which govern the new physics contributions to $B \rightarrow X_s \gamma$ and $B \rightarrow X_s l^+ l^-$ decays considered in this paper. For the SM part, we use the known analytical formulae at NNLO level as given for example in Refs. [5, 17]. The new physics contributions are included through the modifications to the corresponding Wilson coefficients at matching scale $\mu_W \sim M_W$.

From the numerical results and the figures as shown in Sec. III, we found that

(i) For the T2HDM studied here, a light charged Higgs boson with a mass less than 200 GeV is excluded by the data of $B \rightarrow X_s \gamma$ decay at 3σ level. But a charged-Higgs boson with a mass heavier than 300 GeV is still allowed by the data of both $B \rightarrow X_s \gamma$ and $B \rightarrow X_s l^+ l^-$ decay. The data of $B \rightarrow X_s \gamma$ also prefer a small $\delta$, a new CP violating phase appeared in the Yukawa couplings of the T2HDM.

(ii) After the inclusion of new physics contributions, the effective Wilson coefficients $\tilde{C}_{i}^{eff}(m_b)$ ($i = 7\gamma, 9V$ and $10A$), which govern the branching ratio of $B \rightarrow X_s l^+ l^-$ decay, are always SM-like within the considered parameter space of T2HDM. The sign of the interference term in Eq. (16) remains unchanged.

(iii) The new physics contributions to $\tilde{C}_{7\gamma}^{eff}$ and $\tilde{C}_{9V}^{eff}$ can be significant in magnitude respectively for large $\tan \beta$, large $\delta$ and lighter charged-Higgs boson, but they tend to cancel each other and finally result in only a small change to the prediction for the branching ratio of $B \rightarrow X_s l^+ l^-$ decay. This feature can be seen clearly through the numerical results in Table II and the curves shown in last three figures.

(iv) Within the considered parameter space of the T2HDM, the T2HDM predictions for $Br(B \rightarrow X_s l^+ l^-)$ agree well with the SM as well as the measured value within one standard deviation.

APPENDIX A: \( Br(B \to X_s \gamma) \) IN THE SM AND T2HDM

The branching ratio of \( B \to X_s \gamma \) at the next-to-leading order (NLO) in the SM and the leading order (LO) in the T2HDM can be written as \cite{19,22}

\[
B(B \to X_s \gamma) = B_{SL} \left| \frac{V_{ts}^* V_{tb}}{V_{cb}} \right|^2 \frac{6\alpha_{em}}{\pi f(z)\kappa(z)} |\tilde{D}|^2 + A + \Delta, \tag{A1}
\]

where \( B_{SL} = 10.61\% \) is the measured semileptonic branching ratio of B meson, \( \alpha_{em} = 1/128 \) is the fine-structure constant, \( z = m_c^{pole}/m_b^{pole} = 0.29 \pm 0.02 \) is the ratio of the quark pole mass. The function \( f(z) \) and \( \kappa(z) \) have been given in Eqs. \( (25) \) and \( (26) \).

The term \( \tilde{D} \) at low energy scale \( \mu = \mathcal{O}(m_b) \) in Eq. \( (A1) \) corresponds to the subprocess \( b \to s\gamma \)

\[
\tilde{D} = C_{7\gamma}^{SM}(\mu) + V(\mu) + C_{7\gamma}^{NP}(\mu). \tag{A2}
\]

Here \( C_{7\gamma}^{SM}(\mu) \) denotes the SM part of the Wilson coefficient \( C_{7\gamma}(\mu) \) at NLO level, and the explicit expression of \( C_{7\gamma}^{SM}(\mu) \) at both LO and NLO level can be found easily in Ref. \cite{12}.

The new physics part of the Wilson coefficient \( C_{7\gamma} \) and \( C_{8g} \) at the matching scale \( M_W \) are currently known at LO level and have been given in Eqs. \( (7) \) and \( (8) \). At the low energy scale \( \mu = \mathcal{O}(m_b) \), the leading order Wilson coefficients \( C_{7\gamma}^{NP}(\mu) \) and \( C_{8g}^{NP}(\mu) \) can be written as

\[
C_{7\gamma}^{NP}(\mu) = \eta^{46}_{23} C_{7\gamma}^{NP}(M_W) + \frac{8}{3} \left( \eta^{44}_{23} - \eta^{46}_{23} \right) C_{8g}^{NP}(M_W), \tag{A3}
\]

\[
C_{8g}^{NP}(\mu) = \eta^{44}_{23} C_{8g}^{NP}(M_W), \tag{A4}
\]

where \( \eta = \alpha_s(M_W)/\alpha_s(\mu) \), and the Wilson coefficient \( C_{8g}^{NP}(M_W) \) has been given in Eq. \( (8) \).

The function \( V(\mu) \) in Eq. \( (A1) \) is defined as \cite{22}

\[
V(\mu) = \frac{\alpha_s(\mu)}{4\pi} \left\{ \sum_{i=1}^{8} C_i^0(\mu) \left[ r_i + \frac{1}{2} \gamma_i^0 \ln \frac{m_b^2}{\mu^2} \right] - \frac{16}{3} C_{7\gamma}^0(\mu) \right\}, \tag{A5}
\]

where the functions \( r_i \) \( (i = 1, \ldots, 8) \) are the virtual correction functions (see Appendix D of Ref. \cite{22}), \( \gamma_i^0 \) are the elements of the anomalous dimension matrix which govern the evolution of the Wilson coefficients from the matching scale \( M_W \) to lower scale \( \mu \). The values of \( \gamma_i^0 \) can be found in Ref. \cite{22}.

In Eq. \( (A1) \), the term \( A = A(\mu) \) is the the correction coming from the bremsstrahlung process \( b \to s\gamma g \) \cite{22}

\[
A(\mu) = \frac{\alpha_s(\mu)}{\pi} \sum_{i,j=1:i\leq j}^{8} \text{Re} \left\{ C_i^0(\mu) [C_j^0(\mu)]^* f_{ij} \right\}. \tag{A6}
\]

The coefficients \( f_{ij} \) have been defined and computed in Refs. \cite{23,24}. We here use the explicit expressions of those relevant \( f_{ij} \) as given in Appendix E of Ref. \cite{22}.

Finally, the term \( \Delta \) in Eq. \( (A1) \) denotes the non-perturbative corrections \cite{23,24},

\[
\Delta = \frac{\delta_{NP}}{m_b^2} \left| C_{7\gamma}(\mu) \right|^2 + \frac{\delta_{NP}}{m_c^2} \text{Re} \left\{ [C_{7\gamma}^0(\mu)]^* [C_2^0(\mu) - \frac{1}{6} C_1^0(\mu)] \right\}. \tag{A7}
\]
with
\[ \delta_{\gamma}^{\text{NP}} = \frac{\lambda_1}{2} - \frac{9}{2} \lambda_2, \quad \delta_{c}^{\text{NP}} = -\frac{\lambda_2}{9}, \]  
(A8)

where \( \lambda_2 = \frac{(m_B^2 - m_{\bar{B}}^2)}{4} = 0.12 \text{ GeV}^2 \) and \( \lambda_1 = 0.5 \text{ GeV}^2 \).

In the expressions of \( V(\mu) \), \( A(\mu) \) and \( \Delta \), the superscript “0” means that the corresponding Wilson coefficients at LO level will be used. The numerical results show that the new physics contributions to “small quantities” \( A(\mu) \) and \( \Delta \) are very small in magnitude and can be neglected safely.
