OPTIMIZATION OF PRE-PRODUCTION AND PRODUCTION OPERATIONS IN THE FORESTRY INDUSTRY USING RFID TECHNOLOGY

Zuzana Šoltysová; Lukáš Skarupa

Keywords: RFID technology, pre-production operations, production operations, forestry industry

Abstract: The main objective of this paper is to improve logistics and design to improve the register timber in stock and timber in the sale itself to optimalization of pre-production and production operations in the forestry industry. The proposal could improve the registration using RFID technology. The proposal based on RFID technology will ensures smooth and easy flow of information. Technology will be introduced in stocks, which will result in better record keeping and transfer of timber storage and at the same time will be introduce RFID technology in the timber sale.

1 Introduction

RFID technology is defined as radio frequency identification, and it is a form of automatic identification and data capture. The technology utilizes the transmission of information via the electromagnetic field by radio-frequency signals. It consists of four basic parts: a label reader and antenna and computer unit with software. RFID technology is a system which, uses its elements, captures and transmits data stored in the labels and displays them on a computer through the reader. It can be used in all areas related to manufacturing, logistics, transportation, registration, then in automotive and electronics industries as well as in other areas. Interest for this type of technology is increasingly growing.

The functioning process of RFID technology:
1. The label contains a chip and a helical antenna. Chip is inserted into the data. The antenna communicates with the reader.
2. The reader is also part of the antenna. The reader is a device that captures via an antenna and provides data transfer, which reader identify.
3. Computer Unit: includes software that displays data from the reader [3].

2 Pre-production operations in the forestry industry

Pre-production operations include:
1. Planning
   Planning in the forest enterprises includes the following plans: NHP - National economic plan and PSL - The care program of the forest. NHP is drawn by national economic center. PSL is implemented for all forest lands, which are located in the Slovak Republic [7].
felling in forests dying as a result of industrial emissions. [1]. The next figure (Figure 1) describes work organisation of production operations in the forestry industry.

2. Reforestation
Forest regeneration is the process by which there is a replacing of the adult forest with the new forest. It is one of the basic activities of cultivation. There are three kinds of forest regeneration, namely: restoration of natural, artificial or combined. Natural regeneration is carried out under the parent stand. The process is linked to the possible impacts of the arrived seeds on bare surface or directly under the parent stand. In order to correct natural regeneration is necessary in order to achieve favorable conditions. Artificial regeneration is carried out by means of sowing seeds or planting seedlings. Therefore, it is more expensive than natural regeneration. It raises the cost of planting and planting seedlings. Combined recovery is a combination of natural and artificial regeneration. If you can not ensure natural regeneration of the whole area, then it is necessary for filling the artificial surface to ensure recovery [2].

3. Extracting – production technologies
In the production process there is a change of raw product to final product. Extracting production processes change the trees in the forest to wood assortments. Extracting – production technology uses three main felling methods which are classified according to the degree of processing skidding:
- Method of product lines,
- Trunk method,
- Tree method

Product lines method performed in the stand clinker, limbing, if necessary debarking, cut up into individual tribes range. In the trunk method, the trees are cut down, debarking. When the tree method leads to the execution of woodlice in other working operations are performed at selected place (OM) [1].

4. Felling and limbing
First phase for wood extraction is felling (separation of above-ground tree from the ground). In terms of terrain in Slovakia, felling is carried out only by saw. Working felling operation consists of the following operations:
- Determine the direction the tree will fall,
- Modification of workplace,
- Modification of the bottom of the felling of the tree.
- Creating a notch
- The execution of the main cut,
- Rake in the direction of tree fall,
- Adaptation of the butt end and stump [1].

5. Wood sortimentation
Felled trees from forests are not regulated, so they are not suitable for sale. Therefore wood sortimentation must be made; it specifies the conditions of customers in terms of tree species, shape and quality.

6. Gathering of wood
Gathering wood is an activity related to movement of the timber stand at OM. Activity is carried out either wholly in the whole area of the timber from the forest stock, or it is divided into sections.

7. Wood handling
The essence is to regulate branched trunk to selections according to customer requirements. Wood manipulation according to individual tree species includes the assessment allowable size and thickness of pruning, sorting to selections, labelling and storing in heaps by product range. [3] Wood sortimentation is governed by the standard STN 48 0055 for coniferous trees and STN 48 0056 for deciduous trees [5], [6].

Wood assortments:
1st class - logs and veneer production, musical instruments and special technical needs.
2nd Class - cutouts for the production of plywood, matches, sports, technical and other special needs.
3rd Class - cutting logs, derricks, mining, construction, and the sleepers for various purposes without further processing
4th Class - mining logs, poles and pole stage, coniferous wood for trees.
5th Class - wood intended for the mechanical and chemical processing.
6th Class - wood for fuel [5], [6].

8. Transfer of wood
Wood transportation is provided in two ways:
1. The transport of wood from the forest to the upper stock. These are stocks for temporary storage wood. For a long tree, i. j. of 12.5 m in the upper stock, wood is shortened, so as to be able to transport over public roads,
2. Transfer of wood from upper forest stock or from lower forest stock. There is a further manipulation of the timber [7]. Last wood transport is carried out at the sale, so that the logs are transported to the customer by trailers or articulated vehicle. Hydraulic hand is used to loading the timber on the vehicle [1].

4 Application of RFID technology in the forestry industry
RFID technology will be used in the stocks, in the wood auctions, in the sales of wood and it improves the stock
registration. Currently, registration of timber from the forest to the stock works by pedigree timber transport and processing, where are recorded information about timber. This card contains several lines, and per line must be written of tree species, diameter, length, quality, wood volume in m3 etc. After the application of RFID technology should be all the necessary information entered into the tag. The stock would have the appropriate technology that would simply have registered incoming and outgoing timber.

Labels and catalogues are used at the auction of wood in company. Labels are placed on the timber and showed the number. Relevant information - of tree species, diameter and length are assigned to the numbers in the catalogue, which will receive each auction participant. The application of this technology could replace the labels by RFID tags, where the information will be saved. The worker has a manual RFID reader, would have only scans the tag and all the information as of tree species, diameter and length of the date and place of workload would be immediately viewed. It would be more transparent and easier for consumers and would not have to look for information in the catalogue.

This proposal would be also useful in the sales of wood. If customers want certain tree species of a given diameter and length and quality, the employee, attendant computer with the appropriate software, knows that in a stock is what the customer requires. It would be therefore a quick and easy download and storage timber into and from the stock, and it improves processing time. After the application of this technology would be significantly improved the flow of information storage, and an improvement in the sale of wood. It is important to choose each element appropriately to achieve efficient transfer of information.

The following picture (Figure 2) describes process of RFID technology.

**Function and location of the tag:**
Tag is placed on the forehead of wood that will be further shortened and edited, it will be removed in unloading. It is advisable to select the type of the tag memory R / O (read only), it contains only the data entered during marking the timber, and it cannot be simply changed. Removed tags are rejected, as they contain only the data entered during marking the timber, and device stored in them to a computer unit. Antenna would be connected to the stock, it can be possible to monitor the timber from felling in the forest to the final customer.

Application of RFID technology in felling activity:
1. RFID tags contain a chip with memory and a helical antenna. Information on tree species, diameter, length, date of wood felling and place of wood felling will be stored in the chip.
2. Tag will have a metal casing and it will be charged with the plastic pins on each of the logs for the collection from OM to the stock. In particular, tag will be placed on the front of the log.
3. Information will be inserted into the chip and immediately sent to the foresters in stock. There would be no problem in accepting the identification in stocks or any theft of wood.
4. Wood loaded on a truck goes to the stock.
5. The antenna stored on the gateway captures the tag information after a truck entrance to the stock area.
6. The tag is located in the electromagnetic field of antenna, and thus tags are capable of transmitting a radio signal.
7. The reader placed in the stock reads information.
8. Read information will be displayed on a computer unit.

Timber can be easily and quickly identify, and count using tags. Thanks to tag attached to the timber and device stored in the stock, it can be possible to monitor the timber from felling in the forest to the final customer.
Next figure (Figure 3) shows application of RFID technology in the stock.

![Application of RFID technology in the stock](image)

The legend: Red color - antenna, it transfers information using an antenna to the office. Green color - reader, reader obtains the information and subsequently transfers it to the computer unit. Blue color - computer unit displays the information on the monitor. Yellow color - a place designed for the localization of tags in case of wood sales.

Conclusions

Computer unit would be connected through the card via WiFi. Computer unit will be operated by trained personnel. This proposal would improve the flow of information and the sale of wood and also reduce the theft and loss of wood. Another advantage of the proposal is that the wood could not be lost. It is predicted that the losses from timber felling to its transport to the stock consist of about 20%. After the application of the RFID technology should be reduced by 10%. Moreover, by recording the wood using RFID technology will not downshift the timber from a higher category to a lower category. It would also save time of workers, improving organization of work and running of the process of registration of logs in stock. The investment in this technology would be great benefit for business. This proposal would make simpler a sale of logs.
