Abstract

We consider order preserving \(C^3\) circle maps with a flat piece, irrational rotation number and critical exponents \((\ell_1, \ell_2)\).

We detect a change in the geometry of the system. For \((\ell_1, \ell_2) \in [1, 2]^2\) the geometry is degenerate and it becomes bounded for \((\ell_1, \ell_2) \in [2, \infty)^2 \setminus \{(2,2)\}\).

When the rotation number is of the form \(\lfloor abab \cdots \rfloor\); for some \(a, b \in \mathbb{N}^*\), the geometry is bounded for \((\ell_1, \ell_2)\) belonging above a curve defined on \([1, +\infty[^2\).

As a consequence we estimate the Hausdorff dimension of the non-wandering set \(K_f = S^1 \setminus \bigcup_{i=0}^{\infty} f^{-i}(U)\). Precisely, the Hausdorff dimension of this set is equal to zero when the geometry is degenerate and it is strictly positive when the geometry is bounded.

Key words: Circle map, Irrational rotation number, Flat piece, Critical exponent, Geometry and Hausdorff Dimension.

MSC-2010: 37E10.

Acknowledgements: The author was partially supported by the Centre d’Excellence Africain en Science Mathématique et Applications (CEA-SMA).

I would sincerely thank Prof. M. Martens and Prof. Dr. L. Palmisano for introducing me to the subject of this paper, his valuable advice, continuous encouragement and helpful discussions. I thank Prof. Dr. Carlos Ogouyandjou for having participated presentations related to this work.

1 Introduction

We study a certain class of weakly order preserving, non-injective (on an interval exactly; called flat piece) circle maps which appear naturally in the
study of Cherry flows on the two dimensions torus (see [8, 11, 14, 15]), non-
invertible continuous circle map (see [7]) and of the dependence of the rotation
interval on the parameter value for one-parameter families of continuous circle
maps (see [16]). The dynamics of circle maps with a flat interval has been
intensively explored in the past years, see [3, 5, 7, 14, 16, 17]
We discuss the geometry of the non-wandering set (set obtained by removing
from the circle all pre-images of the flat piece). Where the geometry is con-
cerned, we discover a dichotomy; which generalize the one found in [5]. Some
of our maps show a "degenerate geometry", while others seem to be subject to
the "bounded geometry".
Before we can explain more precisely our results, we introduce our class,
adopt some notations and present basic lemmas.

1.1 The class of functions

We fix \( \ell_1, \ell_2 \geq 1 \) and we consider the class \( \mathcal{L} \) of continuous circle maps \( f \) of
degree one for which an arc \( U \) exists so that the following properties hold:
1. The image of \( U \) is one point.
2. The restriction of \( f \) to \( S^1 \setminus U \) is a \( C^3 \)-diffeomorphism onto its image.
3. Let \( (a, b) \) be a preimage of \( U \) under the projection of the real line to \( S^1 \).
   On some right-sided neighborhood of \( b \), \( f \) can be represented as
   \( h_r((x - b)^{\ell_2}) \);
   where, \( h_r \) is \( C^3 \)-diffeomorphism on a two-sided neighbourhood of \( b \). Analog-
gously, on a left-sided neighborhood of \( a \), \( f \) equals
   \( h_l((x - a)^{\ell_1}) \);
   In the following, we assume that \( h_l(x) = h_r(x) = x \). In fact, it is possible
to effect \( C^3 \) coordinate changes near \( a \) and \( b \) that will allow us to replace
both \( h_l \) and \( h_r \) by the identity function.
Let \( F \) be a lift of \( f \) on the real line. The rotation number \( \rho(f) \) of \( f \) is defined
(independently of \( x \) and \( F \)) by

\[
\rho(f) := \lim_{n \to \infty} \frac{F^n(x) - x}{n}(\mod 1).
\]

Let \( (q_n) \) be the sequence of denominators of the convergents of \( \rho(f) \) (irrational)
defined recursively by \( q_1 = 1, q_2 = a_1 \) and \( q_{n+1} = a_nq_n + q_{n-1} \) for all \( n \geq 3 \);
with,

\[
\rho(f) = [a_0a_1 \cdots] := a_0 + \frac{1}{a_1 + \frac{1}{a_2 + \frac{1}{\ddots}}}. 
\]

Additional Assumption

Let \( f \in \mathcal{L} \). We say that \( Sf \) (the Schwarzian derivative of \( f \)) is negative if,

\[
Sf(x) := \frac{D^3f(x)}{Df(x)} - \frac{3}{2} \left( \frac{D^2f(x)}{Df(x)} \right)^2 < 0; \quad \forall x, \ Df(x) \neq 0; \quad (A1)
\]
With, $D^nf$ the $n^{th}$ derivative of $f$; for $n \in \mathbb{N}$.

We will assume in the proof of the first part of Theorem 1 that $f$ has a negative negative Schwarzian derivative.

1.2 Notations and Definitions

The fundamental notations are established in [5] (p.2-3). Let $f \in \mathcal{L}$.

1. For every $i \in \mathbb{Z}$, the writing $f^i(U)$ means $f^i(U)$.

2. Let $I$ and $J$ be two intervals. $(I, J)$ is the interval between $I$ and $J$. $[I, J] := I \cup (I, J)$ and $(I, J) := (I, J) \cup J$. $|I|$ is the length of the interval $I$, $|[I, J]| := |I| + |(I, J)|$ and $|(I, J)| := |J| + |(I, J)|$. We say that $I$ and $J$ are comparable when $|I|$ and $|J|$ are comparable. That means, there is $k > 0$ such that, $\frac{1}{k}|I| < |J| < k|I|$.

3. For any sequence $\Gamma_n$ and for any real $d$, we adopt the writings:

$$
\Gamma_n^{d(\ell_1, \ell_2)} := \begin{cases} 
\Gamma_n^{d\ell_1} & \text{if } n \equiv 0[2] \\
\Gamma_n^{d\ell_2} & \text{if } n \equiv 1[2]
\end{cases}
$$

1.3 Discussion and statement of the results

Scaling ratios

The sequence

$$
\alpha_n := \frac{|-q_n, 0|}{|q_n, 2|} = \frac{|(f^{-q_n}(U), U)|}{|(f^{-q_n}(U), U)| + |f^{-q_n}(U)|}
$$

measure the geometry near a critical point. In fact, it serves as scaling relating the geometries of successive dynamic partitions.

The geometry is said degenerate when $\alpha_n$ goes to zero and the geometry is bounded, when $\alpha_n$ is bounded away from zero.

The study of this geometry is parametrised by rotation number and critical exponents. In [6], for pairs $(\ell, \ell)$; $\ell > 1$ and $\rho$ irrational number of bounded type (i.e. $\max_n \alpha_n < \infty$), the authors found a transition between degenerate geometry and bounded geometry. In fact, they show under (A1) that, if $1 < \ell \leq 2$ and $\rho \in \mathbb{R} \setminus \mathbb{Q}$, then the geometry is degenerate and it is bounded (independently of (A1)) if $\ell > 2$ and $\rho$ is irrational number of bounded type. In [4], for $\ell > 1$, the author proved that the class of function $f$ of critical exponents $(1, \ell)$ or $(\ell, 1)$ have a degenerate geometry. In [15], the authors show that, for the maps in $\mathcal{L}$ with Fibonacci rotation number, when the critical exponents $(\ell_1, \ell_2)$ belong in $(1, 2)^2$, the geometry is degenerate. Let us note that, differently from other previous works, information on the geometry of the system is obtained by the study of the asymptotic behaviour of the renormalization operator.

In the present paper, we consider the cases where the critical exponents $(\ell_1, \ell_2)$ belong in a subdomain (containing the previous domains) of $[1, \infty)^2$; also, the rotation number is not necessarily Fibonacci type and the results do not depend on the renormalization operator as in [9]. We use the formalism presented in [5], which is based on recursive inequalities analysis of $\alpha_n$. For technical reason, in the case of bounded geometry, we introduce the vector sequence
1.3 Discussion and statement of the results

Introduction

\[ v_n := (-\ln \alpha_n, -\ln \alpha_{n-1}) \] and, the new recursive inequality is controlled by a \(2 \times 2\) matrix. When the rotation number is bi-periodic (\(\rho = \{abab\ldots; a, b \in \mathbb{N}\) ), the \(2 \times 2\) matrix has two eigenvalues (depending on rotation number and critical exponents) \(\lambda_1 \in (0, 1)\) and \(\lambda_u > 0\). The equation \(\lambda_u = \lambda_u((a, b); (\ell_1, \ell_2)) = 1\) defines a curve \(C_{\lambda_u=1}\) (presented above) which separates the \((\ell_1, \ell_2)\) plan into two components \(C_{\lambda_u>1}\) (below the curve) and \(C_{\lambda_u<1}\).

Main result

Let \(f \in \mathcal{L}\) with critical exponents \((\ell_1, \ell_2)\). Then,
1. the scaling ratio \(\alpha_n\) goes to zero when \((\ell_1, \ell_2) \in [1, 2]^2\), \(\rho \in \mathbb{R} \setminus \mathbb{Q}\) and \((A1)\) holds.
2. the scaling ratio \(\alpha_n\) bounded away from zero when \((\ell_1, \ell_2) \in [2, \infty)^2 \setminus \{(2, 2)\}\) and \(\rho\) is bounded type.
3. the scaling ratio \(\alpha_n\) bounded away from zero when \((\ell_1, \ell_2) \in C_{\lambda_u<1}\) and \(\rho\) is bi-periodic.

Estimation of Hausdorff Dimension of the non-wandering set. In the symmetric case \((\ell_1 = \ell_2 = \ell)\), in [8], for \(f \in \mathcal{L}\) with bounded type rotation number, the author shows that, if \(\ell \in (1, 2]\), then the Hausdorff dimension of the non-wandering set is equal to zero and that, if \(\ell > 2\), then the Hausdorff dimension of the non-wandering set is strictly greater than zero. This result generalizes the one in [19] where the author treats the maps in \(\mathcal{L}\) with critical exponents \((1, 1)\). Let us note that, the results in [8] are more general (they only depend on geometry); precisely, if the rotation number is the bounded type, then, the Hausdorff Dimension of the non-wandering set is equal to zero when the geometry is degenerate and it is strictly greater than zero when the geometry is bounded; so we have the following result which is proved at the end of the paper.

**Corollary 1.1.** Let \(f \in \mathcal{L}\) with critical exponent \((\ell_1, \ell_2)\) with bounded type rotation number. Then,
1. the Hausdorff dimension of the non-wandering set is equal to zero when \((\ell_1, \ell_2) \in [1, 2]^2\) and \((A1)\) holds and for the pairs \((\ell, 1); \ell > 1;\)
2. the Hausdorff dimension is strictly bigger than zero when \((\ell_1, \ell_2) \in [2, \infty)^2 \setminus \{(2, 2)\}\;
3. the Hausdorff dimension is strictly bigger than zero when \((\ell_1, \ell_2) \in C_{\lambda_u<1}\) and \(\rho\) is bi-periodic.
The following remark will simplify statements and proofs of results.

**Remark 1.2.** Let us note that, our setting has some inherent symmetry. This will simplify statements and proof of our results.

## 2 Tools

### 2.1 Cross-Ratio Inequalities

**Notation 2.1.** We denote by $\mathbb{R}_4^+$, the subset of $\mathbb{R}^4$ defined by

$$
\mathbb{R}_4^+ := \{(x_1, x_2, x_3, x_4) \in \mathbb{R}^4, \text{ such that } x_1 < x_2 < x_3 < x_4\}.
$$

The following result can be found in [1] (Theorem 2)

**Proposition 2.2.** The Cross-Ratio Inequality (CRI).

Let $f \in \mathcal{L}$. Let $(a, b, c, d) \in \mathbb{R}_4^+$. The cross-ratio $Cr$ is defined by

$$
Cr(a, b, c, d) := \frac{|b - a||d - c|}{|c - a||d - b|}
$$

and the cross-ratio $Poin$ is defined by

$$
Poin(a, b, c, d) := \frac{|d - a||b - c|}{|c - a||d - b|}.
$$

The distortion of the cross-ratio $Cr$ and cross-ratio $Poin$ are given respectively by

$$
D_{Cr}(a, b, c, d) := \frac{Cr(f(a), f(b), f(c), f(d))}{Cr(a, b, c, d)}
$$

and

$$
D_{Poin}(a, b, c, d) := \frac{Poin(f(a), f(b), f(c), f(d))}{Poin(a, b, c, d)}.
$$

Let us consider a set of $n + 1$ quadruples $\{a_i, b_i, c_i, d_i\}$ with the following properties:

1. Each point of the circle belongs to at most $k$ intervals $(a_i, d_i)$;
2. The intervals $(b_i, c_i)$ do not intersect $U$.

Then there is $C_k, C'_k > 0$ such that the following inequalities hold

$$
\prod_{i=0}^{n} D_{Cr}(a_i, b_i, c_i, d_i) \leq C_k
$$

and

$$
\prod_{i=0}^{n} D_{Poin}(a_i, b_i, c_i, d_i) \geq C'_k.
$$

Observe that, $Poin + Cr = 1$. Thus, by the 1.5 Lemma in [2] we have the following result.

**Proposition 2.3.** Let $f$ be a $C^3$ function such that the Schwarzian derivative is negative. Then, $C'_k > 1$; that is, $C_k < 1$. 
Remark 2.4. Let $I$ and $J$ be two intervals finite and non-zero length such that, $I \cap J = \emptyset$. We assume that, $J$ is on the right of $I$ and we put $I := [a, b]$ and $J := [c, d]$, then

$$\text{Cr}(I, J) := \frac{|I||J|}{|[I, J]|([I, J])} = \text{Cr}(a, b, c, d)$$

and

$$\text{Poin}(I, J) := \frac{|(I, J)||[I, J]|}{|[I, J]|} = \text{Poin}(a, b, c, d).$$

Fact 2.5. Let $f \in \mathcal{L}$. Let $l(U)$ and $r(U)$ be the left and right endpoints of $U$ (the flat piece of $f$) respectively. There are a left-sided neighborhood $I_l$ of $l(U)$, a right-sided neighborhood $I_r$ of $r(U)$ and three positive constants $K_1, K_2, K_3$ such that the following holds

1. If $y \in I_l$ with $l_1 := l$, $l_2 := r$, then
   $$K_1|l_i(U) - y|^i \leq |f(l_i(U)) - f(y)| \leq K_2|l_i(U) - y|^{i-1},$$
   $$K_1|l_i(U) - y|^i \leq \frac{df}{dx}(y) \leq K_2|l_i(U) - y|^{i-1}.$$  

2. If $y \in (x, z) \subset I^i$, with $z$ the closest point to the flat interval $U$ then
   $$\frac{|f(x) - f(y)|}{|f(x) - f(z)|} \leq K_3 \frac{|x - y|}{|x - z|}.$$

The first part of Fact 2.5 implies that,

$$f_{|P_i} \approx k_i x^i; \ i = 1, 2. \ \text{We assume that, } \ k_1 = k_2. \ \text{(A2)}$$

We need this assumption to prove that $\alpha_n$ goes to zero (Lemma 2.9 and Lemma 3.2).

2.2 Basic Results

Proposition 2.6. Let $n \geq 1$.

- The set of “long” intervals consists of the intervals
  $$\mathcal{A}_n := \{(\hat{z}, q_n + i); \ 0 \leq i \leq q_{n+1} - 1\}.$$

- The set of “short” intervals consists of the intervals
  $$\mathcal{B}_n := \{(q_{n+1} + i, \hat{z}); \ 0 \leq i \leq q_n - 1\}.$$

The set $\mathcal{P}_n := \mathcal{A}_n \cup \mathcal{B}_n$ covers the circle modulo the end points and the flat piece and it is called the $n^{th}$ dynamical partition.

The dynamical partition produced by the first $q_{n+1} + q_n$ pre-images of $U$ is denoted $\mathcal{P}^n$. It consists of

$$\varphi_n := \{-\hat{z}; \ 0 \leq i \leq q_{n+1} + q_n - 1\}$$

together with the gaps between these sets. As in the case of $\mathcal{P}_n$ there are two kinds of gaps, “long” and “short”.
• The set of “long” intervals consists of the intervals
  \[ A_n := \{ (-\frac{q_n}{i}, -i) =: I_{n+1}^i; \ 0 \leq i \leq q_n + 1 \}. \]

• The set of “short” intervals consists of the intervals
  \[ B_n := \{ (-i, -\frac{q_n}{i+1}) =: I_{n+1}^i; \ 0 \leq i \leq q_n + 1 \}. \]

**Proposition 2.7.** The sequence \(|(0, q_n)|\) tends to zero at least exponentially fast.

**Proposition 2.8.** If \(A\) is a pre-image of \(U\) belonging to \(P_n\) and if \(B\) is one of the gaps adjacent to \(A\), then \(\frac{|A|}{|B|}\) is bounded away from zero by a constant that does not depend on \(n, A\) or \(B\).

**Lemma 2.9.** The sequence
  \[ f(\sigma_n) = \frac{|(1, q_n + 1)|}{|(q_{n-1} + 1, 1)|} \]

is bounded.

The proofs of these results can be found in [5] (proof of the Proposition 1, Proposition 2 and Lemma 1.3).

A proof of the following Proposition can be found in [3] theorem 3.1 p.285.

**Proposition 2.10** (Koebe principle). Let \(f \in L\). For every \(\varsigma, \alpha > 0\), there exist a constant \(\zeta(\varsigma, \alpha) > 0\), such that, the following holds. Let \(T\) and \(M \subset T\) be two intervals and let \(S, D\) be the left and the right component of \(T \setminus M\) and \(n \in \mathbb{N}\). Suppose that:
1. \(\sum_{i=0}^{n-1} f^i(T) < \varsigma,\)
2. \(f^n : T \rightarrow f^n(T)\) is a diffeomorphism,
3. \(\frac{|f^n(M)|}{|f^n(S)|} < \alpha.\)

Then,
\[ \frac{1}{\zeta(\varsigma, \alpha)} \leq \frac{Df^n(x)}{Df^n(y)} \leq \zeta(\varsigma, \alpha), \quad \forall x, y \in M; \]

that is,
\[ \frac{1}{\zeta(\varsigma, \alpha)} \cdot \frac{|A|}{|B|} \leq \frac{f^n(A)}{f^n(B)} \leq \zeta(\varsigma, \alpha) \cdot \frac{|A|}{|B|}, \quad \forall A, B \text{ (intervals)} \subseteq M; \]

where,
\[ \zeta(\varsigma, \alpha) = \frac{1 + \alpha}{\alpha} e^{C\varsigma} \]

and \(C \geq 0\) only depends on \(f\).

**Remark 2.11.** Let \(f \in L\). Given \(n > 1, T\) and \(M\) as before. \(f^n : T \rightarrow f^n(T)\) is diffeomorphism if only if, for all \(0 \leq i \leq n-1, f^i(T) \cap \overline{U} = \emptyset\); where, \(\overline{U}\) designates the closure of \(U\).
3 Proof of results

Let us put together (parameter) sequences which are frequently used in this section.

\[ \alpha_n = \frac{|(-q_n, 0)|}{|(-q_n, 0)|}, \quad \sigma_n = \frac{|(0, q_n)|}{|q_n-1, 0|}, \quad s_n := \frac{|-q_n, 0, 1|}{|0, -q_n-2|}, \quad \tau_n := \frac{|(0, q_n)|}{|q_n-2|} \]

and

\[ \beta_n(k) = \frac{|(-q_n+kq_n-1, 0)|}{|(-q_n+kq_n-1, 0)|}, \quad k = 0, 1, \ldots, a_{n-1}. \]

3.1 Proof of the first part of main result

3.1.1 A priori Bounds of \( \alpha_n \)

**Proposition 3.1.** Let \( n \in \mathbb{N} \) and \((\ell_1, \ell_2) \in \Omega_0 = [1, 2]^2\).

For all \( \alpha_n \),

\[ \frac{\ell_1 + \ell_2}{\alpha_n} < 0.55; \]

for at least every other \( \alpha_n \)

\[ \frac{\ell_1 + \ell_2}{\alpha_n} < 0.3, \]

If

\[ \frac{\ell_1 + \ell_2}{\alpha_n} > 0.3, \]

then either,

\[ \frac{\ell_1 + \ell_2}{\alpha_n} < 0.44 \quad \text{or} \quad \alpha_{n+1} < 0.16. \]

**Proof.** For every \( n \in \mathbb{N} \) and \( k = 0, 1, \ldots, a_{n-1} \), we define the parameter sequences

\[ \gamma_{1,n}(k) := |(-q_n+kq_{n-1}, 0)|, \quad \gamma_{1,n-1} := \gamma_{1,n-1}(0), \quad \gamma_n(k) = \frac{\gamma_{1,n}(k)}{\gamma_{1,n-1}} \]

\[ \gamma_n^{(\ell_1, \ell_2)}(k) := \frac{\gamma_{1,n}(k)}{\gamma_{1,n-1}} \quad \text{if} \quad n \in 2\mathbb{Z} \quad \text{and} \quad \gamma_n^{(\ell_1, \ell_2)}(k) := \frac{\gamma_{1,n}(k)}{\gamma_{1,n-1}} \quad \text{if} \quad n \in 2\mathbb{Z} + 1. \]

These notations simplify the formalization of the following lemma which will play an important (essential) role in the proof of **Proposition 3.1**

**Lemma 3.2.** For \( n \) large enough and for every \( k = 0, 1, \ldots, a_{n-1} - 1 \), the following inequality holds

\[ \frac{(\beta_n(k)^{\ell_1, \ell_2} + \alpha_n^{\ell_1, \ell_2} \gamma_n^{(\ell_1, \ell_2)}(k))(1 + \gamma_n^{(\ell_1, \ell_2)}(k))}{(1 + \alpha_n^{\ell_1, \ell_2} \gamma_n^{(\ell_1, \ell_2)}(k))} \leq s_n \beta_n(k+1). \]  \( (3.1) \)

**Proof.** Let \( n \) be an even non negative integer large enough. For fixed \( k = 0, 1, \ldots, a_{n-1} - 1 \), according to the assumption \( (A2) \), the left hand side of \( (3.1) \) is equal to the cross-ratio

\[ \text{Poin}(-q_n+kq_{n-1}+1,-q_{n-1}+1). \]

Applying \( f^{q_{n-1}} \), by expanding cross-ratio property, we get the inequality. \( \square \)
3.1 Proof of the first part of main result

The left hand side is a function of the three variables \( \beta_n(k^{\ell_1,\ell_2}, \alpha_{n-1}^{\ell_1,\ell_2} \) and \( \gamma_n^{(\ell_1,\ell_2)} \). Observe that the function increases monotonically with each of the first two variables. However, relatively to the third variable, the function reaches a minimum. To see this, take the logarithm of the function and check that the first derivative is equal to zero only when

\[
(\gamma_n^{(\ell_1,\ell_2)})^2 = \frac{\beta_n(k^{\ell_1,\ell_2})}{\alpha_{n-1}^{\ell_1,\ell_2}}.
\]

By substituting this value for \( \gamma_n^{(\ell_1,\ell_2)} \) in (3.1), we get that

\[
\left( \frac{\beta_n(k^{\ell_1,\ell_2} + \frac{\ell_1 \ell_2}{2}}{1 + \beta_n(k^{\ell_1,\ell_2} + \frac{\ell_1 \ell_2}{2}} \right) \leq s_n \beta_n(k + 1). \tag{3.2}
\]

Put:

\[
x_n(k) := \min\{\beta_n(k^{\ell_1,\ell_2} + \frac{\ell_1 \ell_2}{2}, \alpha_{n-1}^{\ell_1,\ell_2}\} \quad \text{and} \quad y_n(k) := \beta_n(k^{\ell_1,\ell_2} + \frac{\ell_1 \ell_2}{2}).
\]

Since \( \beta_n(k + 1) \leq y_n(k + 1) \), substituting the above variable into (3.2) gives rise to a quadratic inequality in \( x_n(k) \) whose only root in the interval \((0, 1)\) is given by

\[
\frac{\sqrt{s_n y_n(k + 1)}}{1 + \sqrt{1 - s_n y_n(k + 1)}};
\]

that is,

\[
x_n(k) = \min\{\beta_n(k^{\ell_1,\ell_2} + \frac{\ell_1 \ell_2}{2}, \alpha_{n-1}^{\ell_1,\ell_2}\} \leq \frac{\sqrt{s_n y_n(k + 1)}}{1 + \sqrt{1 - s_n y_n(k + 1)}}. \tag{3.3}
\]

**Lemma 3.3.** There is a subsequence of \( \alpha_n \) including at least every other \( \alpha_n \), such that

\[
\limsup \alpha_n \leq 0.3.
\]

**Proof.** We use the following elementary lemma in [5].

**Lemma 3.4.** The function

\[
h_n(z) = \frac{\sqrt{s_n z}}{1 + \sqrt{1 - s_n z}}
\]

moves points to the left, \( h(z) < z \), if \( z \geq 0.3 \) and \( n \) is large enough.

We select the subsequence.

1. **The initial term:** there exists \( n - 2 \in \mathbb{N} \), such that \( \alpha_{n-2}^{\ell_1,\ell_2} \leq 0.3 \). This comes directly from the properties of the function \( h_n \) (Lemma 3.4) and from (3.3).

2. **The next element:** suppose that \( \alpha_{n-2} \) has been selected. If

\[
x_n(k) = \alpha_{n-2}^{\ell_1,\ell_2} \quad \text{or} \quad \alpha_{n-2}^{\ell_1,\ell_2} \leq 0.3,
\]

for some \( k = 0, 1, \cdots a_{n-1} - 1 \), then, we select \( \alpha_{n-1} \) as the next term. Otherwise, \( \alpha_n \) is the next term. Thus, the sequence is constructed.
Corollary 3.5. For the whole sequence \((\alpha_n)\) we have
\[
\limsup \alpha_n \leq 0.3
\]
Moreover,
- if \(\alpha_n - 1\) does not belong to the subsequence \((\alpha_n)\) defined by the Lemma 3.3
then either
\[
\frac{\ell_1 \ell_2}{
\alpha_{n-1} - 1
} < 0.44 \quad \text{or} \quad \frac{\ell_1 \ell_2}{\alpha_n - 1} < 0.16
\]

Proof. Observe that the function
\[
H : (s, t) \in \mathbb{R}_+^2 \mapsto F(s, t) = \frac{s + t}{1 + st}
\]
is symmetric and for fixed \(s\), the function \(F(s, \cdot)\) reaches its minimum in zero by taking the value \(s\). Therefore, for every \(s, t \geq 0, s, t \leq s + t + \ell_1 \ell_2 n\).

So,
\[
\frac{\ell_1 \ell_2}{\alpha_n - 1}, \frac{\ell_1 \ell_2}{\alpha_n - 1} \leq \frac{\ell_1 \ell_2}{\alpha_n - 1} + \frac{\ell_1 \ell_2}{\alpha_n - 1}.
\]  \(3.4\)

Thus, according to that \(\alpha_n - 1\) is an element of the sequence and suppose that \(\alpha_n - 1\) do not belong to the previous subsequence of the Lemma 3.3, then, it follows from \(3.2\) that the right member of \(3.4\) is estimated as following
\[
\frac{\ell_1 \ell_2}{\alpha_n - 1} + \frac{\ell_1 \ell_2}{\alpha_n - 1} \leq \sqrt{s_n \beta_n (1)} \approx \beta_n (1) \approx 0.3. \(3.5\)
\]

Also,
\[
\min\{\alpha_n - 1, \alpha_n - 1\} = \alpha_n - 1 \leq 0.3. \(3.6\)
\]
Thus, if \(\alpha_n - 1 \geq 0.16,\) then by combining this with \(3.5\) and \(3.6\), we obtain the desired estimate.

The Proposition 3.1 is proved.

3.1.2 Recursive formula of \(\alpha_n\)

Proposition 3.6. Let \(n\) be integer large enough,
1. if \(\ell_1, \ell_2 > 1,\) we have
\[
\alpha_{2n}^{\ell_1} \leq M_{2n}(\ell_1) \alpha_{2n-2}^{\ell_1} \quad \text{and} \quad \alpha_{2n+1}^{\ell_2} \leq M_{2n+1}(\ell_2) \alpha_{2n-1}^{\ell_2}.
\]  \(3.7\)
where,
\[
M_n(\ell) = s_{n-1}^2 \cdot \frac{\ell}{2 \ell - 1} \cdot \frac{1}{1 + \sqrt{1 - \frac{2(\ell - 1)}{\ell} s_{n-1} \alpha_{n-1}}} \frac{1}{1 - \alpha_n - 1} \cdot \frac{\sigma_n}{\sigma_{n-2}}.
\]
2. if \( \ell_1 = \ell_2 = 1 \), then
\[
\alpha_n \leq W_n \cdot \frac{\sigma_n}{\sigma_{n-2}} \alpha_{n-2}. \tag{3.8}
\]

**Proof.** We treat the case \( n \) even and the case \( n \) odd is treated in a similar way. Recall that,
\[
\alpha_n = \frac{|(−qn, 0)|}{|−qn, 0|}.
\]
For every \( n \) even large enough, by Proposition 2.7 and point 2 of Fact 2.5, applying \( f \) to the equality, we get
\[
\alpha_{\ell_1}^n = \frac{|(−qn + 1, 1)|}{|−qn + 1, 1|},
\]
which is certainly less than the cross-ratio
\[
\text{Poin}(−qn + 1, (1, −qn−1 + 1)).
\]
Since the cross-ratio \( \text{Poin} \) is expanded by \( f^{qn−1} \), then,
\[
\alpha_{\ell_1}^n < \delta_n(1)s_n(1), \tag{3.9}
\]
with,
\[
\delta_n(k) := \frac{|(−qn + kqn−1, kqn−1)|}{|−qn + kqn−1, kqn−1|},
\]
and
\[
s_n(k) := \frac{|−qn + kqn−1, 0|}{|−qn + kqn−1, 0|}.
\]
If \( a_{n−1} = 1 \), by multiplying and dividing the right member of (3.9) by \( \alpha_n^2 \), we obtain directly (3.11).

Suppose that \( a_{n−1} > 1 \) and estimate \( \delta_n(k) \). By the Mean Value Theorem (Lagrange), \( f \) transforms the intervals defining the ratio \( \delta_n(k) \) into a pair whose ratio is
\[
\frac{u_k}{v_k} \delta_n(k)
\]
with \( u_k \) being the derivative of \( f(x_{\ell_1}) \) at a point in the interval
\[
U_k := (−qn + kqn−1, kqn−1),
\]
and \( v_k \) being the derivative of \( f(x_{\ell_1}) \) at a point in the interval
\[
V_k := [−qn + kqn−1, kqn−1].
\]
Note that, for \( n \) sufficiently large,
\[
u_1 < v_1 < u_2 < v_2 \cdots < v_{a_{n−1}}.
\]
We see that the image of \( \delta_n(k) \) by \( f \) is smaller than:
\[
\text{Poin}(−qn + kqn−1 + 1, (kqn−1 + 1, −qn−1 + 1)).
\]
Once again, by expanding cross-ratio property \((f^{n-1})\), it follows that,
\[
\frac{u_k}{v_k} \delta_n(k) \leq s_n(k + 1) \cdot \delta_n(k + 1).
\] (3.10)

Multiplying (3.10) for \(k = 0, ..., a_n - 1\), and substituting the resulting estimate of \(\delta_n(1)\) into (3.9), we obtain:

\[
\alpha_{\ell_1} \leq \delta_n(a_n - 1) \frac{v_{a_n - 1}}{u_1} s_n(1) \cdots s_n(a_n - 1).
\]

Observe that,
\[
s_n(1) \cdots s_n(a_n - 1) < s_n \quad \text{and} \quad v_{a_n - 1} u_1 \leq \left| \frac{-q_n - 2, 0}{q_n - 1, 0} \right| \cdot \delta_n(a_n - 1);
\]

which can be rewritten in the form
\[
\alpha_{\ell_1} \leq s_n \nu_{n-2} \mu_{n-2} \alpha_{n-2}^2;
\] (3.11)

with,
\[
\nu_{n-2} := \left| \frac{-q_n - 2, 0}{q_n - 1, 0} \right| \quad \text{and} \quad \mu_{n-2} := \left| \frac{-q_n - 2, a_n - 1 q_{n-1}}{-q_n - 2, 0} \right|.
\]

It remains to estimate \(\nu_{n-2}\) and \(\mu_{n-2}\) to end this part. For \(\nu_{n-2}\), observe that,
\[
\left| \frac{-q_n - 2, 0}{q_n - 1, 0} \right| \leq \left| \frac{q_n + 1, 0}{q_n - 1, 0} \right|
\]
so that,
\[
\nu_{n-2} \leq \frac{1}{\sigma_{n-1} \sigma_{n-2}} \cdot \frac{1}{1 - \alpha_{n-2}}.
\] (3.12)

The estimation of \(\mu_{n-2}\) is facilitated by the following elementary lemma in [5].

**Lemma 3.7.** Let \(\ell \in (1, 2)\). For all numbers \(x > y\), we have the following inequality:
\[
\frac{x^\ell - y^\ell}{x^\ell} \geq \left( \frac{x - y}{x} \right) \left[ \ell - \frac{\ell(\ell - 1)}{2} \left( \frac{x - y}{x} \right) \right].
\]

Now, apply \(f\) into the intervals defining the ratio \(\mu_{n-2}\). By Lemma 3.7 the resulting ratio is larger than
\[
\mu_{n-2}(\ell_1 - \ell_1(\ell_1 - 1)/2) \mu_{n-2}.
\]

The cross-ratio **Poin**
\[
Poin(-q_n + 1, (q_n - 1 + 1, 1));
\]
that is,
\[\left| \frac{(-q_{n-2} + 1, q_{n-1} + 1)}{(-q_{n-2} + 1, q_{n-1} + 1)} \right|\]
is larger again. Thus, by expanding cross-ratio property on \( f^{q_{n-2}} \), we obtain:
\[
\mu_{n-2} (\ell_1) - \frac{\ell_1 (\ell_1 - 1)}{2} \mu_{n-2} \leq s_{n-1} \sigma_{n} \sigma_{n-1}.
\]
(3.13)

By solving this quadratic inequality, we obtain
\[
\mu_{n-2} \geq \frac{1 + \sqrt{1 - \frac{2}{\ell_1} (\ell_1 - 1) s_{n-1} \sigma_{n} \sigma_{n-1}}}{\ell_1 - 1}.
\]
(3.14)

Thus, by combining the (3.13) and (3.14), we obtain
\[
\mu_{n-2} < \frac{2}{\ell_1} \cdot \frac{1}{1 + \sqrt{1 - \frac{2}{\ell_1} (\ell_1 - 1) s_{n-1} \sigma_{n} \sigma_{n-1}}}.
\]
(3.15)

Since, \( \sigma_{n} \sigma_{n-1} < \alpha_{n-1} \), the first inequality in (3.7) follows by combining the inequalities (3.11), (3.12) and (3.15). Likewise, the second inequality in (3.7) is obtained by following suitably the same reasoning as previously.

### 3.1.3 \( \alpha_n \) go to zero

If \( \ell_1 = \ell_2 = 1 \), then by Proposition 3.1 \( \prod_{k=2}^{k=n} W_k^{\ell_1} \) goes to zero; thus, by composing the inequality obtained by \( f \), since \( f(\sigma_n) \) is bounded (Lemma 2.9), then the result follows.

Note that, the cases where the critical exponents are of the form \((1,\ell)\) or \((\ell,1)\); with \( \ell > 1 \), are treated in [4].

Now, Let us suppose that \( \ell_1, \ell_2 > 1 \).

Technical reformulation of the Proposition 3.6.

Let \( W_n \) be a sequence defined by
\[
M_n(\ell) = W_n(\ell) \frac{\sigma_n}{\sigma_{n-2}}.
\]

Let
\[
M_n'(\ell) := M_n(\ell) \alpha_{n-2}^{\ell_1} \quad \text{and} \quad W_n'(\ell) := W_n(\ell) \alpha_{n-2}^{\ell_1}
\]
The recursive formula (3.7) can be written for \( n \) even in the form:
\[
\alpha_{n}^{\ell_1} \leq W_n'(\ell_1) \frac{\sigma_n}{\sigma_{n-2}} \alpha_{n-2}^{\ell_1}.
\]
so,
\[
\alpha_{n}^{\ell_1} \leq \prod_{k=2}^{k=n} W_k'(\ell_1) \frac{\sigma_n}{\sigma_0} \alpha_0^{\ell_1}.
\]
\( \prod_{k=2}^{k=n} W_k'(\ell_1) \) goes to zero
Observe that, the size of \( W'_n(\ell_1) \) is given by the study of the function

\[
W'_n(x, y, \ell_1) = \frac{1}{\ell_1 + \frac{\ell_1}{2} \sqrt{1 - \frac{2(\ell_1 - 1)}{\ell_1}}} \frac{y^{\ell_1 - 2}}{1 - y^{\ell_1}}.
\]

The meaning of variation of \( W'_n(x, y, \ell_1) \) relative to the third variable is given by the following lemma in [5]).

**Lemma 3.8.** For any \( 0 < y < \frac{1}{\sqrt{e}} \), \( x \in (0, 1) \) and \( \ell_1 \in (1, 2] \) the function \( W'_n(x, y, \ell_1) \) is increasing with respect to \( \ell_1 \).

**Analyse the asymptotic size of \( W'_n(2) \)**

Since the hypotheses of the Lemma 3.8 are satisfied (Proposition 3.1), the only remaining point is the verification of the convergence of \( \prod_{i=1}^n W'_i(2) \).

- If \( \alpha_{n-2} < (0.3) \ell_1 \), then \( W'(2) < W'(0.55, 0.16, 2) < 0, 9 \).
- If not, then by the Proposition 3.1 \( W'(2) < W'(0.3, 0.44, 2) < 0.98 \) or else, \( W'_{n+1}(2)W'_n(2) < W'(0.55, 0.16, 2)W'(0.16, 0.55, 2) < 0.85 \).

**Corollary 3.9.** Let \( \ell_1, \ell_2 \in [1, 2] \). If \( 1 < \ell_1 < 2 \) respectively \( 1 < \ell_2 < 2 \), then \( \alpha_{2n} \) respectively \( \alpha_{2n+1} \) goes to zero least double exponentially fast. And, if \( \ell_1 = 2 \) or 1 respectively \( \ell_2 = 2 \) or 1, then \( \alpha_{2n} \) respectively \( \alpha_{2n+1} \) goes to zero least exponentially fast.

**Proof.** Let \( n := 2p_n \in \mathbb{N} \). From the analysis of the asymptotic size of \( W'_i(2) \), it follows that, when \( n \) goes to infinity, \( \prod_{i=0}^n W'_i(\ell_1) \) goes to zero and \( \alpha_n \) does so. Therefore,

\[
\prod_{i=0}^n M_i(\ell_1)
\]

goes to zero when \( n \) goes to infinity. Thus, by the Proposition 3.6 for \( n \) even, there is \( \lambda_0 \) such that

- if \( 1 < \ell_1 < 2 \),
  \[
  \alpha_n \leq \lambda_0 \left( \frac{1}{2} \right)^{p_n},
  \]
- and if \( \ell_1 = 1, 2 \),
  \[
  \alpha_n \leq \lambda_0^2.
  \]

The case \( n \) odd is treated the same way.

3.2 **Proof of the second part of main result**

In this section we find a bounded geometry domain.
3.2 Proof of the second part of main result

3.2.1 Recursive Affine Inequality of order two on $\alpha_n$

Let

$$\kappa_n := \frac{|(0, q_n)|}{|(0, -q_{n-1})|}.$$

**Remark 3.10.** Since the point $q_{n-2}$ lies in the gap between $-q_{n-1}$ and $-q_{n-1} + q_{n-2}$ of the dynamical partition $P_{n-2}$, then by the Proposition 2.8, $\tau_n/\alpha_{n-1}$ and $\kappa_n$ are comparable.

**Proposition 3.11.** For any bounded type rotation number, there is a uniform constant $K$ so that

$$\kappa_n > K (\alpha_{n-1})^{1 - \ell_2},$$

and

$$\kappa_{n+1} > K (\alpha_n)^{1 - \ell_1}.$$

**Proof of the Proposition:** If $a_n = 1$, it comes down to showing that the sequence $\kappa_n$ is bounded away from zero; which becomes relatively very simple. In fact, suppose that, $|(q_n, -q_{n-1})| \leq |(0, q_n)|$, then

$$\kappa_n = \frac{|(0, q_n)|}{|(0, -q_{n-1})|} \geq \frac{1}{2},$$

else, $\kappa_n$ is greater than

$$\frac{|-q_{n+1}|}{|-q_{n+1}, -q_{n-1}|};$$

which by the Proposition 2.8 is bounded away from zero.

In the following part of the proof, we suppose that $a_n > 1$ and the following lemma in [5] (Lemma 4.1) is used.

**Lemma 3.12.** The ratio

$$1 - \beta_n(i) = \frac{|-q_n + iq_{n-1}|}{|q_n + iq_{n-1}, 0|}$$

is bounded away from zero by a uniform constant for all $i = 0, \ldots, a_{n-1}$.

**Lemma 3.13.** For every $n \in \mathbb{N}$ and for all $i = 0, \ldots, a_{n-1}$, there is a uniform constant $K$ such that

$$\beta_n(i)^{\ell_1, \ell_2} \geq \beta_n(i + 1).$$

**Proof.** For $n$ large enough and for fixed $i = 0, \ldots, a_{n-1}$, by the Proposition 2.7 and the Fact 2.5, we have:

$$\beta_n(i)^{\ell_1, \ell_2} = \frac{|-q_n + kq_{n-1} + 1, 1|}{|q_n + iq_{n-1} + 1, 1|};$$

which is greater than,

$$\text{Cr}([-q_{n-2} + 1, -q_n + iq_{n-1} + 1, (-q_n + iq_{n-1} + 1, 1)).$$
3.2 Proof of the second part of main result

By applying the cross-ratio inequality under \( f^{q_n-2} \), by the Fact 2.5, the resulting ratio is greater than

\[
\text{Cr}([-q_n-2+1, -q_n+1]-q_n-2+1, 1),
\]

\[
\text{Cr}([-q_n+1, -q_n+1]-q_n-2+1, q_n-2+1])
\]
times a uniform constant. We now repeat this sequence of steps \( a_{n-2} = 1 \) times: Apply \( f^{q_n-2} \), discard the interval containing 0 and use the point 2 of the Fact 2.5, and replace the result by a cross-ratio spanning the intervals \(-q_n-2+1\). At the end, this will produce the cross ratio

\[
\text{Cr}([-q_n-2+1, -q_n+1]-q_n-2+1, 1),
\]

\[
\text{Cr}([-q_n+1, -q_n+1]-q_n-2+1, q_n-2+1])
\]

And finally, by applying \( f^{q_n-3} \), since by the Lemma 3.12, the interval containing \(-q_n-2+q_n-3\) bounded away from zero, then resulting ratio is

\[
\frac{|(-q_n+(i+1)q_n-1, q_n-1)|}{|(-q_n+(i+1)q_n-1, q_n-1)|}
\]
times a uniform constant. Thus, since \(-q_n+q_n-1\) lies between \(-q_n+(i+1)q_n-1\) and \(q_n-1\), then, by the Lemma 3.12, this ratio is comparable to \(\beta_n(i+1)\). 

\[
\begin{align*}
\text{Back to the proof of the Proposition 3.11} & \quad \text{Observe by the Proposition 2.8 that} \\
& \quad \text{and} \\
& \quad \text{are comparable. Therefore,} \\
& \quad \text{By combining this with the Lemma 3.13 we have the Proposition 3.11} \\
\end{align*}
\]

Recursive Affine Inequality of order two on \( \alpha_n \)

**Proposition 3.14.** If \( \rho(f) \) is of bounded type, then there is a uniform constant \( K \) so that,

\[
\alpha_{2n} \geq K (\alpha_{2n-1})^{\frac{\ell_1}{\ell_2} - a_{2n}} (\alpha_{2n-2})^{\frac{\ell_2}{\ell_1} - a_{2n-1}}
\]

and

\[
\alpha_{2n+1} \geq K (\alpha_{2n})^{\frac{\ell_1}{\ell_2} - a_{2n+1}} (\alpha_{2n-1})^{\frac{\ell_2}{\ell_1} - a_{2n}}
\]
Proof of the Proposition  
If \( n \) is even and large enough, then
\[
\alpha_{\ell n} = \frac{|(-q_n + 1, 1)|}{|q_n + 1, 1|};
\]
which in turn is larger than the product of two ratios
\[
\xi_{1,n} = \frac{|(-q_n + 1, 1)|}{|q_n + 1, -q_n - 1 + 1|} \quad \text{and} \quad \xi_{2,n} = \frac{|(-q_n + 1, -q_n - 1 + 1)|}{|q_n + 1, -q_n - 1 + 1|}.
\]

Lemma 3.15. For all \( n \) even large enough
\[
\xi_{1,n} \geq K \tau_n.
\]

Proof. Observe that \( \xi_{1,n} \) is greater than
\[
Cr ((-q_n + 1, 1), (-q_n - 1 + 1)).
\]
By applying CRI on \( f_{q_n - 1} \) and discarding the intervals containing \( 0 \). Repeat this \( a_{n-1} - 1 \) times more: By the Fact 2.5 the resulting ratio is large than
\[
Cr ((-q_n - 2 - q_n - 1 + 1, (a_{n-1} - 1)q_n - 1 + 1), (1, -q_n - 1 + 1)).
\]
Apply \( f_{q_n - 1} \), and discard the intervals containing the flat interval. Apply \( f \), replace the resulting by the cross-ratio
\[
Cr (((-q_n - 2 + 1, q_n - 1 + 1), (1, -q_n - 1 + 1))).
\]
Thus, by CRI on \( f_{q_n - 1} \) and the inequalities above, we obtain
\[
\xi_{1,n} > \frac{|(q_n - 2, -q_n - 3)|}{|(q_n - 1, -q_n - 3)|} \tau_n
\]
(3.16)
The first factor on the right hand side of 3.16 is greater than
\[
\frac{|-q_n - 3|}{|0, -q_n - 3|};
\]
which by the Proposition 2.8 goes away from zero. The Lemma is proved.

Lemma 3.16. There is a uniform constant \( K \) so that, for all \( n \)
\[
\xi_{2,2n} \geq K (a_{2n-2})^{\tau_{n+1}} \quad \text{and} \quad \xi_{2,2n+1} \geq K (a_{2n-1})^{\tau_{n+1}}.
\]

Proof. If \( a_{n-1} = 1 \), then \( \xi_{2,n} \) is greater than
\[
Cr ((-q_n - 2 + 1, -q_n + 1), (-q_n + 1, -q_n - 1 + 1)).
\]
By applying CRI \( (q_n - 2 - 1) \), the ratio resulting is greater than
\[
Cr ((-q_n - 2 + 1, -q_n - 1 + 1), (-q_n - 1 + 1, -q_n - 3 + 1))
\]
times a uniform constant. Thus, by applying CRI to this ratio with \( f_{q_n - 1} \), inequalities above and the Proposition 2.8 the result follows.
3.2 Proof of the second part of main result

Now, suppose that \( a_{n-1} > 1 \) then \( \xi_{2,n} \) is greater than
\[
Cr([-q_n + q_{n-1} + 1, -q_n + 1], (-q_n + 1, -q_{n-1} + 1)).
\]
By applying \( f^{q_{n-1}} \) to this ratio, it follows from the Lemma 3.12 that
\[
\xi_{2,n} \geq K_1 \beta_n(1).
\]
And the lemma follows from this by using Lemma 3.13 modulo the fact that
\[
\beta_n(a_{n-1}) = \alpha_{n-2}.
\]

Combining the Lemma 3.15, the Lemma 3.16, the Proposition 3.11, and the Remark 3.10, the result of the Proposition 3.14 follows.

Remark 3.17. By the inequality obtained from the Proposition 3.14, the sequence \( \nu_n \) defined by
\[
\nu_n = -\ln \alpha_n
\]
verifies the following Recursive Affine Inequalities of order two for every \( n > 0 \)
\[
\nu_{2n} \leq \frac{\ell_2}{\ell_1} \cdot t_2(a_{2n}) \nu_{2n-1} + \ell_1^{-a_{2n-1}} \nu_{2n-2} + \overline{K}_i
\]
and
\[
\nu_{2n+1} \leq \frac{\ell_1}{\ell_2} \cdot t_1(a_{2n+1}) \nu_{2n} + \ell_2^{-a_{2n}} \nu_{2n-1} + \overline{K}_i;
\]
with
\[
t_i(j) = \frac{1 - \ell_i^{-j}}{\ell_i - 1}.
\]

3.2.2 Analysis of Recursive Affine Inequality

We will prove that the sequence \( \nu_n \) is bounded. Let us consider the sequence of vectors \( (\nu_n) \) defined by
\[
\nu_n = \begin{pmatrix} \nu_n \\ \nu_{n-1} \end{pmatrix},
\]
the vector given by
\[
\overline{\nu} = \begin{pmatrix} \overline{K}_i \\ 0 \end{pmatrix}
\]
and the sequence matrix
\[
A_{\ell_1, \ell_2}(2n) = \begin{pmatrix} \frac{\ell_2}{\ell_1} \cdot t_2(a_{2n}) & \ell_1^{-a_{2n-1}} \\ 1 & 0 \end{pmatrix}
\]
and
\[
A_{\ell_1, \ell_2}(2n + 1) = \begin{pmatrix} \frac{\ell_1}{\ell_2} \cdot t_1(a_{2n+1}) & \ell_2^{-a_{2n}} \\ 1 & 0 \end{pmatrix}.
\]
say associated matrix to the Recursive Affine Inequalities \((3.17)\) and \((3.18)\) respectively; in this sense that \((3.17)\) and \((3.18)\) can be rewritten respectively in the form:

\[
v_{2n} \leq A_{\ell_1,\ell_2}(2n)v_{2n-1} + \varpi \quad \text{and} \quad v_{2n+1} \leq A_{\ell_2,\ell_1}(2n+1)v_{2n} + \varpi.
\]

(3.19)

Therefore, for every \(n := 2p_n + r_n\); with \(p_n \in \mathbb{N}^* \) and \(r_n \in \{0, 1\}\), we have

\[
v_n \leq \overline{A}_{\ell_1,\ell_2}(n)\overline{A}_{\ell_1,\ell_2}(n-2)\cdots \overline{A}_{\ell_1,\ell_2}(2 + r_n)v_{2-r_n} + \left(Id + \sum_{i=4+2r_n}^{n} \overline{A}_{\ell_1,\ell_2}(n)\overline{A}_{\ell_1,\ell_2}(n-2)\cdots \overline{A}_{\ell_1,\ell_2}(i)\right)\overline{\varpi},
\]

where,

\[
\overline{A}_{\ell_1,\ell_2}(n) = A_{\ell_1,\ell_2}(n)A_{\ell_1,\ell_2}(n-1).
\]

Observe that, if \((\ell_1, \ell_2)\) is very close to an element of the set \(\{(a, \infty), (\infty, b), (\infty, \infty), a, b \in \mathbb{R}\}\)

\(\overline{A}_{\ell_1,\ell_2}(n)\) is diagonalizable with nonnegative eigenvalues and at most one is strictly positive; that is, \(1/\ell_1 \) or \(1/\ell_2 \) and as \(\ell_1, \ell_2 > 2\), then, \(\overline{A}_{\ell_1,\ell_2}(n)\) contracts the Euclidean metric; therefore, \(v_n\) (also \(v_n\) and \(\alpha_n\)) is bounded. In the following analysis, we suppose that \(1 < \ell_1, \ell_2 < C < \infty\); for some \(C\) in \(\mathbb{R}^+\).

**Lemma 3.18.** Fix \((\ell_1, \ell_2) \in [2, \infty)^2\). The sequence

\[
\overline{A}^n_{\ell_1,\ell_2} := \overline{A}_{\ell_1,\ell_2}(n)\overline{A}_{\ell_1,\ell_2}(n-2)\cdots \overline{A}_{\ell_1,\ell_2}(4)
\]

is bounded (uniformly) by \(\max\{\ell_1/\ell_2, \ell_2/\ell_1\}\).

**Proof.** Observe that, for all \(n \in \mathbb{N}\),

\[
\overline{A}_{\ell_1,\ell_2}(n) \leq \left(\frac{1-\beta_2(2)}{\ell_2} - \frac{\beta_2(2)\ell_2}{\ell_2 - 1}\right) := \overline{B}_{\ell_1,\ell_2}(n);
\]

with,

\[
b_{2n}(\ell) = b_{2n} := \ell^{-\alpha_{2n}} \quad \text{and} \quad b_{2n+1}(\ell) = b_{2n+1} := \ell^{-\alpha_{2n+1}}.
\]

Let be a sequence \((x_n)_{n \in \mathbb{N}}\) defined by:

\[
(x_n)_{n \in \mathbb{N}} := \{1 - \beta_2(2), b_n(2); n \in \mathbb{N}\}.
\]

Remark that for every \(n \in \mathbb{N}\), \(x_n \in [2^{-a}, 1 - 2^{-a}]\); where, \(a := \max\{a_n, n \in \mathbb{N}\}\).

Thus, by setting

\[
\overline{B}^n_{\ell_1,\ell_2} = \left(\frac{d^{1,n}}{\ell_2} \frac{d^{2,n}}{\ell_2} \frac{d^{3,n}}{\ell_2} \frac{d^{4,n}}{\ell_2}\right),
\]

it follows that for every \(i \in \{1, 2, 3, 4\}\), there is \(x_{k_{i,j}}, j = p_{n-2}, \cdots, n - 2\) such that:

\[
d^{i,n} \leq \sum_{j=p_{n-2}}^{n-2} x_{k_{i,j}} \cdots x_{k_{i,j}} \leq 1
\]

This proves the lemma. \(\square\)
3.2 Proof of the second part of main result

Proposition 3.19. When \((\ell_1, \ell_2) \in [2, \infty)^2 \setminus \{(2, 2)\}\), then \(\overline{A}_{\ell_1, \ell_2}^{\infty}\) contracts the Euclidean metric provided \(n\) is large enough. The scale of the contraction is bounded away from 1 independently of \(\ell_1\) and \(\ell_2\) and the particular sequence \(b_n\), whereas the moment when the contraction starts depends on the upper bound of \(b_n\).

Proof. For fixed \(n \in \mathbb{N}\), putting

\[
\overline{A}_{\ell_1, \ell_2}^{n} = \left( \begin{array}{c} d^{1,n}(z_1, z_2) \\ \frac{d^{2,n}(z_1, z_2)}{d^{1,n}(z_1, z_2)} \end{array} \right)
\]

with \(z_1 = 1/(\ell_1 - 1)\) and \(z_2 = 1/(\ell_2 - 1)\) Thus, \(d^{i,n}(z_1, z_2), i = 1, 2, 3, 4\) are polynomials of respective degree \(n - 2, n - 3, n - 3\) and \(n - 4\); whose coefficients belong to the interval \([1 - \alpha, 1 - \ell^{-\alpha}]\); with, \(\ell = \max\{\ell_1, \ell_2\}\). For fixed \(i \in \{1, 2, 3, 4\}\), we denote by \(d^{i,n}_j\) the coefficients of \(d^{i,n}(z_1, z_2)\). Let us put:

\[
\begin{cases}
  d_1(2) = 1 & \text{and} & d_1(i) = 0; & i = 1, 3, 4 \\
  d_2(3) = 1 & \text{and} & d_2(i) = 0; & i = 1, 2, 4.
\end{cases}
\]

Then by the Lemma 3.18, the sums

\[
\sum_{j=0}^{p_{n-2}} d^{i,j}(z_1, z_2) j + d_1(i) j + d_2(i); \quad i = 1, 2, 3, 4
\]

are uniformly bounded. Therefore, for every \(i \in \{1, 2, 3, 4\}\)

\[
\sum_{j=k}^{\infty} d^{i,j}(z_1, z_2) j + d_1(i) j + d_2(i) \rightarrow 0, \quad \text{when} \quad k \rightarrow \infty
\]

Lemma 3.20. For every \(i \in \{1, 2, 3, 4\}\), the sequence \((d^{i,n}_j)\) tends to zero at least exponentially.

Proof. By a simple calculation, we have

\[
d^{1,n}(0, 0) = \prod_{i=1}^{p_{n-2}} b_{n-2i+1}, \quad d^{2,n}(0, 0) = \prod_{i=1}^{p_{n-2}} b_{n-2i}, \quad d^{3,n}(0, 0) = d^{3,n}(0, 0) = 0.
\]

Now, suppose that, for given \(0 < n - 1\) and \(0 < j < n - 1\) all the coefficients \(d^{i,n-1}_j\) \(i \in \{1, 2, 3, 4\}\), tend to zero at least exponentially fast. Then, since

\[
\overline{A}_{\ell_1, \ell_2}^{n} = \overline{A}_{\ell_1, \ell_2}^{n}(n) \frac{\overline{A}_{\ell_1, \ell_2}^{n-1}}{\overline{A}_{\ell_1, \ell_2}^{n-1}}
\]

and by the form of the coefficients of \(\overline{A}_{\ell_1, \ell_2}^{n}(n)\), the Lemma is proved and therefore, the Proposition 3.19.
3.3 Proof of Corollary

**Proposition 3.21.** Let $f \in \mathcal{L}$ with critical exponents $(\ell_1, \ell_2)$ and rotation number $\rho(f) = [abab \cdots]$; for some $a, b \in \mathbb{R}$. If the inequality

$$\sqrt{(\ell_1^{-b} - \ell_2^{-a})^2 + (t_1(b)t_2(a) + 2(\ell_1^{-b} + \ell_2^{-a}))t_1(b)t_2(a) + + t_1(b)t_2(a) + \ell_1^{-b} + \ell_2^{-a} - 2 < 0;$$

holds, then the geometry of $f$ is bounded.

**Proof.** If $\rho(f) = [abab \cdots]$, then

$$\mathcal{X}_{\ell_1, \ell_2} = \left(\begin{array}{cc}
t_1(b)t_2(a) + \ell_1^{-b} & \ell_2 \ell_1^{-a} t_2(a) \\
t_2 & \ell_1^{-a}
\end{array}\right)$$

and these eigenvalues $\lambda_s$ and $\lambda_u$ are defined as following

$$2\lambda_s = -\sqrt{(\ell_1^{-b} - \ell_2^{-a})^2 + (t_1(b)t_2(a) + 2(\ell_1^{-b} + \ell_2^{-a}))t_1(b)t_2(a) + + t_1(b)t_2(a) + \ell_1^{-b} + \ell_2^{-a}$$

and

$$2\lambda_u = \sqrt{(\ell_1^{-b} - \ell_2^{-a})^2 + (t_1(b)t_2(a) + 2(\ell_1^{-b} + \ell_2^{-a}))t_1(b)t_2(a) + + t_1(b)t_2(a) + \ell_1^{-b} + \ell_2^{-a} \cdot$$

Observe that, $\lambda_s \in (0, 1)$. Thus, if $\lambda_u < 1$, then $\mathcal{X}_{\ell_1, \ell_2}$ contracts the Euclidean metric.

This proves the proposition. \qed

3.3 Proof of Corollary

**Lemma 3.22.** Let

$$w_n(i) = \left[\frac{(-q_n + (i + 1)q_{n-1}, -q_n + iq_{n-1})}{-q_n + iq_{n-1}}\right]$$

be a parameter sequence with, $i = 0 \cdots a_{n-1} - 1$. $w_n(i)$, $i = 1 \cdots a_{n-1} - 1$ and $w_n^{0, t_2}(0)$ are comparable to $a_{n-1}$.

**Proof.** Suppose that $a_{n-1} > 1$ and let $i = 1, \cdots, a_{n-1} - 1$. We apply the Proposition 2.10 to

- $T = [-q_n + (i + 1)q_{n-1}, -q_n + (i - 1)q_{n-1}]$,
- $M = (-q_n + (i + 1)q_{n-1}, -q_n + (i - 1)q_{n-1})$,
- $S = -q_n + (i + 1)q_{n-1}$,
- $D = -q_n + (i - 1)q_{n-1}$,
- $f^{q_n -(i-1)q_{n-1}}$.

1. For every $j < q_n - (i - 1)q_{n-1}$, $f^j(T) \cap U = \emptyset$; so $f^{q_n -(i-1)q_{n-1}}$ is diffeomorphism on $T$ (Remark 2.11);
2. the set $\bigcup_{j=0}^{q_n-(i-1)q_n-1} (T)$ covers the circle at most two times;
3. for $n$ large enough, and by the Proposition 2.8 we have

$$\frac{f_{q_n-(i-1)q_n-1}(M)}{f_{q_n-(i-1)q_n-1}(S)} < \frac{f_{q_n-(i-1)q_n-1}(M)}{f_{q_n-(i-1)q_n-1}(D)} = \frac{|(0, -2q_{n-1})|}{|2q_{n-1}|} < K.$$ 

Therefore, it follows from the Proposition 2.10 and Proposition 2.8 ($|q_{n-1}|$ and $|q_n-1|$ are comparable) that $w_n(i)$ and $\alpha_{n-1}$ are comparable.

For $i = 0$ (which is the only case when $a = 1$), we apply the Proposition 2.10 to

- $T = [-q_n + q_{n-1} + 1, -q_n - q_{n-1} + 1],$
- $M = (-q_n + q_{n-1} + 1, -q_n - q_{n-1} + 1),$
- $S = -q_n + q_{n-1} + 1,$
- $D = -q_n - q_{n-1} + 1.$

As before, the hypotheses are satisfied. And for $n$ large enough,

$$w_n^{\ell_1, \ell_2}(0) = \frac{|(-q_n + q_{n-1} + 1, -q_n + 1)|}{|q_n + 1|};$$

which is also uniformly comparable to $\alpha_{n-1}$.

This concludes the proof. \(\square\)

The rest of the proof of Corollary is as in [8] (Theorem 1.4 and Theorem 1.5).
