(Dated: January 11, 2017)

We compute a subset of three, velocity-independent four-loop (and fourth post-Newtonian) contributions to the harmonic-coordinates effective action of a gravitationally interacting system of two point-masses. We find that, after summing the three terms, the coefficient of the total contribution is rational, due to a remarkable cancellation between the various occurrences of $\pi^2$. This result, obtained by a classical field-theory calculation, corrects the recent effective-field-theory-based calculation by Foffa et al. [arXiv:1612.00482]. Besides showing the usefulness of the saddle-point approach to the evaluation of the effective action, and of $x$-space computations, our result brings a further confirmation of the current knowledge of the fourth post-Newtonian effective action. We also show how the use of the generalized Riesz formula [Phys. Rev. D 57, 7274 (1998)] allows one to analytically compute a certain four-loop scalar master integral (represented by a four-spoked wheel diagram) which was, so far, only numerically computed.

I. INTRODUCTION

The analytical study, to ever-increasing accuracy, of the motion and radiation of two compact bodies (with comparable masses) in General Relativity has been vigorously pursued over the last decades, with the aim of helping the construction of accurate templates for the data-analysis pipeline of the network of ground-based interferometric gravitational-wave detectors. And indeed, the bank of 250 000 templates used in the matched-filter searches and data-analyses of the first observing run of advanced LIGO [1] have been defined [2] within the analytical effective-one-body (EOB) formalism [3–7]. The EOB formalism combines, in a suitably resummed format, perturbative, analytical [post-Newtonian (PN)] results on the motion and radiation of compact binaries, with some non-perturbative information extracted from numerical simulations of coalescing black-hole binaries.

In this work we focus on the conservative dynamics of two spinless bodies. The current level of accuracy on the analytical knowledge of this problem is the fourth post-Newtonian (4PN) accuracy. The 4PN Hamiltonian [in Arnowitt-Deser-Misner (ADM) coordinates] of two mass points is non-local in time, and was first obtained in complete form in Ref. [9], based on the computation of the local contributions in Ref. [10]. (Earlier, partial results were obtained in Refs. [11–14].) The non-local action of Ref. [9] was reduced to a local Hamiltonian in Ref. [15]. (This “local reduction” was obtained by using an expansion in powers of the eccentricity, together with suitable redefinitions of the phase-space variables, as detailed in [16].) Since then, the only other attempt to derive the complete 4PN dynamics has been the harmonic-coordinates calculation of Ref. [17]. Most of the terms in the action of Ref. [17] agree with the results of Refs. [9, 15], except a couple of them.

To discuss the discrepancies between the harmonic-coordinates result of Ref. [17] and the ADM-coordinates one of Refs. [9, 10, 15], it is convenient to order the various contributions to the interaction Hamiltonian (which starts by the Newtonian one $-Gm_1m_2/r_{12}$) by means of the powers of the symmetric mass ratio $\nu$. Our notation (besides using $G$ for Newton’s gravitational constant) is

$$M \equiv m_1 + m_2; \; \mu \equiv \frac{m_1m_2}{m_1 + m_2}; \; \nu \equiv \frac{\mu}{M} = \frac{m_1m_2}{(m_1 + m_2)^2}. \; \; (1.1)$$

We denote the two masses of the binary system as $m_1$ and $m_2$, while $r_{12} = |r_{12}|$ (where $r_{12} \equiv x_1 - x_2$) denotes the relative distance. We work here in the center-of-mass system; when doing so in a Hamiltonian framework, one considers the ratio $p/\mu$ (where $p = p_1 = -p_2$) as fixed.

The $\mu$-reduced Hamiltonian $\hat{H}_{4\text{PN}} \equiv \hat{H}_{4\text{PN}}/\mu$ can then be decomposed as

$$\hat{H}_{4\text{PN}} \left( \frac{r_{12}}{GM}, \frac{p}{\mu} \right) = \hat{H}_0^{4\text{PN}} + \nu \hat{H}_1^{4\text{PN}} + \nu^2 \hat{H}_2^{4\text{PN}} + \nu^3 \hat{H}_3^{4\text{PN}} + \nu^4 \hat{H}_4^{4\text{PN}}. \; \; (1.2)$$

Here, $\hat{H}_0^{4\text{PN}}$ describes the 4PN-level contribution to the dynamics of a test mass moving around a central body of mass $M = m_1 + m_2$, while $\nu \hat{H}_1^{4\text{PN}}$ describes the first self-force (1SF) correction to the latter test-mass dynamics, $\nu^2 \hat{H}_2^{4\text{PN}}$ the second self-force (2SF) correction, etc. [In diagrammatic language, computing 1SF effects on the “small mass” $m_1$ (say) corresponds to computing one gravitational loop in the external gravitational field of a black hole of mass $m_2 \gg m_1$.]

---

1 It was shown long ago [5] that the extension effects of compact bodies show up only at the 5PN level, so that they can be modelled by point masses below the 5PN accuracy.
It was shown in Ref. [17] that all the terms that are non-linear in $v$ [i.e. $v^2H_{4PN} + v^4H_{4PN}$] in Eq. (1.2) in their harmonic-coordinate result agree (modulo a suitable contact transformation) with the ADM action of Ref. [9]. The discrepancies are limited to the $\nu$-linear (1S-level) contribution $\nu H_{4PN}$. It was later shown in Ref. [16] that the $\nu$-linear terms in the local reduction [5] of the ADM non-local action were in full agreement with several different (analytical and numerical) gravitational self-force computations (combined with results from EOB theory, and from the first law of binary dynamics [13, 20]), and it was concluded that several claims, and results, of Ref. [17] were incorrect, and must be corrected both by evaluating the energy in keeping with Refs. [9, 15], and by the addition of a couple of ambiguity parameters linked to subtleties in the regularization of infrared and ultraviolet divergences. The values of the needed additional ambiguity parameters (denoted there $\Delta a$ and $\Delta b$, when using the “gauge” $c = 0$) were determined in Ref. [16] to be $\Delta a^{\text{tot}} = \Delta a - 11 \frac{\pi}{4\nu} \Delta C = \frac{217}{35}$ and $\Delta b = 12 \frac{\pi}{15} \Delta C = \frac{12}{7}$ [inserting Eqs. (6.1), (7.4) of Ref. [16] in Eq. (6.3) there]. Recently, Ref. [21] confirmed all those conclusions, and notably the values of the ambiguity parameters (which they denote $-\delta_1 \equiv \Delta a^{\text{tot}}$ and $-\delta_2 \equiv \Delta b$) that must be added to the harmonic-coordinates Hamiltonian to correct it.

Very recently, Ref. [22] applied the so-called effective field theory (EFT) method [23] to the computation of a subset of the contributions to the harmonic-coordinates Lagrangian $L$. Given some specified gauge-fixing additional contribution to the Einstein-Hilbert action [here the standard harmonic-coordinates gauge-fixing term $S_{\text{gf}} = (16\pi G)^{-1} \int d^Dx \sqrt{g} (-\frac{1}{2} \gamma_{\mu\nu} \nabla^\mu \nabla^\nu)$ with $\Gamma^\nu \equiv g^{\mu\nu} \Gamma_{\mu\nu} \Gamma^\mu$], the effective action, $S_{\text{eff}} = \int d\tau L$, describing the conservative dynamics of the binary system can be decomposed in powers of $G$ and of the velocities $v_a, a = 1, 2$ (together with their various time derivatives $\dot{v}_a, \ddot{v}_a, \cdots$) in particular, the structure of the interaction Lagrangian (say up to the 4PN level) is roughly described by expanding the $n$-th power (with $n \leq 4$) on the first rhs of the following sketchy formula (where $c$ denotes the velocity of light):

$$L_{\text{4PN}}^{\text{int}} |_{\text{linear in } v_a} \equiv L_{\text{4PN}}^{\text{int}} |_{(n=4)} + \sum_{n=0,1,2} L_{\text{4PN}}^{\text{int}} |_{(n)} (1.4)$$

with values $n = 0, 1, 2$.

Foffa et al. pointed out [22] three facts: (i) the terms non-linear in accelerations coming from $n = 0$ and $n = 1$ on the rhs of Eq. (1.4) only contribute rational coefficients to the lhs; (ii) the terms quadratic in accelerations coming from $n = 2$ on the rhs contribute the following $\pi^2$-dependent 4PN $O(G^2)$ terms to $L_{\text{4PN}}^{\text{int}} O(G^2)$ linear in $v_a$

$$\frac{105}{32} \pi^2 G^5 m_1 m_2 \frac{1}{c^6 r_{12}^2} \left( \frac{m_1^2 + m_2^2}{m_2 m_1} \right) = \frac{71}{16} \pi^2 G^5 m_1^2 m_2^2 \frac{1}{c^6 r_{12}^2}; (1.5)$$

and (iii) the $\pi^2$-dependent terms [15] coming from the $O(G^2 v^2)$ action coincide with the ($v$- and $\dot{v}$-independent) $\pi^2$-dependent terms present in the full, linear-in-acceleration harmonic-coordinates 4PN Lagrangian derived in Ref. [17] [see Eq. (5.6f) there]. As the latter contributions in the harmonic-coordinates Lagrangian of Ref. [17] agree with corresponding contributions in the ADM Hamiltonian of Ref. [9], one would then conclude (barring a coincidental agreement between two incorrect results) from Eq. (1.4) that the
coefficients entering the $n = 4$ [i.e. $O(G^5)$] contribution to the original (non-linear in derivatives of $v$) 4PN effective Lagrangian $L_{4\text{PN}}^{(n=4)}$ should not contain any $\pi^2$, i.e. should be a rational number. In other words, there should be no new, genuine $\pi^2$ at the $O(G^5)$ level.

However, Foffa et al. \cite{22} have recently reported the computation, within the EFT approach, of the 50 Feynman diagrams contributing to the $n = 4$ [i.e. $O(G^5)$] contribution to $L_{4\text{PN}}^{\text{int}}[x_a, v_a, \dot{v}_a, \cdots]$ in Eq. (1.3). Their results comprise three contributions with $\pi^2$-dependent coefficients, namely

\[
L_{33}^{\text{FMSS}} = (32 - 2\pi^2) \frac{G^5 m_1^3 m_2^3}{c^3 r_{12}^6}, \tag{1.6a}
\]
\[
L_{49}^{\text{FMSS}} = (64 - 6\pi^2) \frac{G^5 m_1^3 m_2^3}{c^3 r_{12}^6}, \tag{1.6b}
\]
\[
L_{50}^{\text{FMSS}} = \left( \frac{248}{9} - \frac{8}{3} \pi^2 \right) \frac{G^5 m_1^3 m_2^3}{c^3 r_{12}^6}. \tag{1.6c}
\]

Note that we cited here twice the quantities respectively denoted $L_{33}$, $L_{49}$ and $L_{50}$ in \cite{22} because it seems that they implicitly assume that the $m_1 m_2$ symmetric Lagrangian contributions $L_{33} \sim L_{49} \sim L_{50} \sim m_1^3 m_2^3$ should be augmented by their 1 $\leftrightarrow$ 2 images, and thereby doubled.

The sum of the three contributions (1.6) contains the $\pi^2$-dependent term

\[
\frac{32}{3} \pi^2 \frac{G^5 m_1^3 m_2^3}{c^3 r_{12}^6} \tag{1.7}
\]

which disagrees with the result of \cite{17} (which is derived with the use of the same, harmonic gauge-fixing term). In terms of the $\mu$-reduced Hamiltonian \cite{12}, this discrepancy is proportional to $\nu^2$, and therefore at the 2SF level. All the contributions $O(\nu^2)$ to the $\mu$-reduced 4PN action agreed (modulo a contact transformation) between the two existing complete 4PN calculations \cite{9} and \cite{17}.

The main aim of the present paper is to perform a new, independent calculation of the three contentious Lagrangian contributions $L_{33}$, $L_{49}$ and $L_{50}$ to decide whether there were subtle, hidden errors in \cite{17} and \cite{9} that coincidentally agree, or whether there is an error in the EFT-theory evaluation of the corresponding Feynman integrals. A secondary aim of the present paper concerns the analytical computation of a certain $d$-dimensional, four-loop “master” Feynman integral, denoted $\mathcal{M}_{4,6}$ in Ref. \cite{22}. This master integral contributes to the values of both $L_{33}$, and $L_{50}$. Though they employed some of the most advanced Feynman-integral computation techniques, Foffa et al. did not succeed in analytically evaluating the $d$-dimensional, four-loop integral $\mathcal{M}_{4,6}$, and had to resort to a many-digit numerical evaluation of the coefficients of the Laurent expansion of $\mathcal{M}_{4,6}(d)$ in powers of $\varepsilon \equiv d - 3$. This evaluation gave very solid numerical evidence for the presence of $\pi^2$ at the $\varepsilon^0$ level, and this has been assumed to be exactly true in the computation of the results Eqs. (1.6).

The two main results of the present paper will be: (i) to show that one can analytically evaluate (by notably using the generalized Riesz formula derived in \cite{27}, which was also crucial to the computation of the local ADM 4PN Hamiltonian computation \cite{10}) the relevant first three terms in the $\varepsilon$ expansion of the four-loop master integral $\mathcal{M}_{3,6}(d = 3 + \varepsilon)$, and, in particular, rigorously prove the presence of $\pi^2$ at the $\varepsilon^0$ level; and (ii) explain away the seeming contradiction following from the presence of $\pi^2$ in the EFT evaluation (1.6) of the four-loop integrals $L_{33}$, $L_{49}$ and $L_{50}$, by showing that a new, independent calculation of these integrals (using, instead of the EFT technique of \cite{22}, the alternative, diagrammatic “field theory” approach to the effective action introduced long ago by Damour and Esposito-Farèse \cite{28}, together with $x$-space techniques, and the use of the generalized Riesz formula), leads to results that crucially differ from the ones cited above in that $\pi^2$ simply cancels out in the sum $L_{33} + L_{49} + L_{50}$.

II. VARIOUS APPROACHES TO THE EFFECTIVE ACTION FOR GRAVITATIONALLY INTERACTING POINT MASSESS

The introduction of a classical “variational principle that takes account of the mutual interaction of multiple particles without introducing fields” dates back to Fokker’s 1929 definition \cite{29} of the following relativistic functional of several worldlines (labelled by $a, b = 1, \ldots, N$) describing $N$ electromagnetically interacting charged point masses (here we use $c = 1$, and all the quantities are defined in a Minkowski spacetime of signature mostly plus)

\[
S_{\text{class}}[x_a(s_a)] = - \sum_a m_a \int ds_a + \frac{1}{2} \sum_{a,b} e_a e_b \int d\sigma_a^x d\sigma_b^y \delta \left( (x_a - x_b)^2 \right). \tag{2.1}
\]

The action (2.1) is obtained by classically “integrating out” the electromagnetic field $A_\mu(x)$ in the usual total relativistic action for the particles and the field, i.e. by replacing the (time-symmetric, Lorenz-gauge) solution of the equation of motion of $A_\mu(x)$ in presence of given worldlines (say $A_\mu^{\text{loc}}[x; x_a(s_a)]$) in the original particle + field action.

The action (2.1) played a central role in the 1949 work of Wheeler and Feynman \cite{30}. Let us also note that Fokker’s original paper features spacetime diagrams of worldlines interacting via time-symmetric propagators. It is therefore probable that the introduction of quantum interaction diagrams (or Feynman diagrams) by Feynman around the same time was partly motivated by Fokker’s classical interaction diagrams. Clear evidence for this is the 1950 paper of Feynman \cite{31} in which he introduces the (complex) quantum effective action for
charged particles defined (in modern notation) through taking the logarithm of a functional integral over the field (in presence of given classical charged worldlines)

\[ e^{\frac{1}{\hbar} S_{\text{eff}}^{\text{quant}}} = \int D\Gamma e^{\frac{1}{\hbar} (S_{\text{partia}} + S_{\text{intia}})}. \] (2.2)

He then explicitly shows that \( S_{\text{eff}}^{\text{quant}} \), (2.2), only differs from its classical counterpart, \( \frac{1}{\hbar} S_{\text{Eff}} \), by the replacement of the (real) time-symmetric propagator \( \delta((x_a - x_b)^2) \) by the (complex) (Stückelberg-)Feynman propagator \( \delta_a((x_a - x_b)^2) \), with \( \delta_a(x) = \frac{i}{4(x^2 + \omega)} = \delta(x^2) + PP \frac{1}{x^2} \).

The gravitational analog of the above classical, effective action for the general relativistic interaction of point masses reads \( S_{\text{eff}}^{\text{class}} \),

\[ S_{\text{eff}}^{\text{class}}[x_a(s_a)] = [S_{\text{pm}} + S_{\text{EH}} + S_{\text{gf}}]g_{\mu\nu}(x)\rightarrow g_{\mu\nu}^{\text{eff}}[x_a(s_a)] \}, \] (2.3)

where \( S_{\text{pm}} = -\sum \int m_a \sqrt{-g_{\mu\nu}(x)} \frac{\partial}{\partial x^\mu} \frac{\partial}{\partial x^\nu} \) denotes the point-mass action, \( S_{\text{EH}} \) the Einstein-Hilbert action, and \( S_{\text{gf}} \) a gauge-fixing term, and where \( g_{\mu\nu}^{\text{eff}}[x_a(s_a)] \) denotes the gauge-fixed solution of Einstein’s equations in presence of given worldlines. The gravitational analog of the above (formally) quantum, effective action reads \( S_{\text{eff}}^{\text{quant}} \),

\[ e^{\frac{1}{\hbar} S_{\text{eff}}^{\text{quant}}} = \int Dg_{\mu\nu} e^{\frac{1}{\hbar} (S_{\text{partia}} + S_{\text{intia}} + S_{\text{gf}})}. \] (2.4)

In the classical limit, one can evaluate the (formal) path integral (2.4) by the saddle point (or stationary phase) approximation. As the extrema with respect to \( g_{\mu\nu}(x) \) of the exponent in (2.4) are simply classical solutions of the gauge-fixed Einstein equations, one immediately sees that (formally)

\[ S_{\text{eff}}^{\text{quant}}[x_a(s_a)] = S_{\text{eff}}^{\text{class}}[x_a(s_a)] + O(h). \] (2.5)

We recalled the above rather well-known facts to clarify that the so-called EFT method (formally based on (2.4)) computes (in the classical limit, and when considering the conservative dynamics) exactly the same quantity as the classical, Fokker (or, for that matter) ADM, reduction method (2.3).

However, the two different definitions of the effective action suggest different technical methods for computing it, and this is where there is a real practical difference

\footnote{Note that this definition is misprinted in Refs. [22] [34], where the lhs of Eq. (2.4) is simply written as \( \frac{1}{\hbar} S_{\text{eff}}^{\text{quant}} \), without the exponential, and without the imaginary unit; these omissions being later corrected by considering connected diagrams and by multiplying the rhs by \(-i\).}

\footnote{However, as discussed in [22] and several subsequent papers, the imaginary part of \( S_{\text{eff}}^{\text{quant}}[x_a(s_a)] \) gives useful information about radiation-damping effects.}

in the traditional PN (or post-Minkowskian) computations of \( S_{\text{eff}} \), and in the EFT-inspired one. First, let us recall that long before the EFT method was set up [23], an alternative, diagrammatic “field theory” approach to the (classically defined) effective action was introduced in Ref. [28]. It was explicitly shown in [28] how the perturbative, post-Minkowskian way of solving the gauge-fixed Einstein’s equations (say in harmonic gauge) leads to a (classical, Feynman-like) diagrammatic expansion of the effective action for the particles of the form (with the normalizations chosen there)

\begin{align*}
S_{\text{eff}} &= S_{\text{free}} + \left[ \frac{1}{2} I \right]_{Gm^2} + \left[ \frac{1}{2} V + \frac{1}{3} T \right]_{G^2m^3} + \left[ \frac{1}{3} + \frac{1}{2} Z + F + \frac{1}{2} H + \frac{1}{4} X \right]_{G^3m^4} + \cdots.
\end{align*}

(2.6)

Here, each letter \( I, V, T, \cdots \) is chosen to evoke a correspondingly shaped diagram, when representing the source by, say, \( \circ \). For instance, the diagram \( I \) denotes the vertical concatenation of two sources, \( \circ \) and \( \circ \), located at the end points of the \( I \), via an intermediate (time-symmetric) gravitational propagator \( | \), say \( \circ \). (Here, the propagator is defined as minus the inverse of the kinetic term, see more discussion of this choice below.) In other words, \( I \) denotes the one-graviton-exchange diagram of the gravitationally interacting source. When decomposing the material, two-body source according to the masses, say \( m_1 \circ_1 + m_2 \circ_2 \), the \( I \) diagram gives three contributions: two self-gravity ones, \( O(Gm_1^2) \) and \( O(Gm_2^2) \), and a relativistic Newtonian interaction one: \( Gm_1m_2 \frac{\epsilon}{\epsilon} \). Similarly, \( T \) denotes a diagram where three sources (located at the end points of the \( T \)) are connected via three gravitational propagators that meet at a cubic vertex in the middle of the upper branch of the \( T \). In addition, Ref. [28] gave explicit rules for computing the numerical coefficients to be put in front of each diagram to correctly evaluate the effective action. It is sometimes convenient (to better exhibit the physics contained in the effective action) to draw each individual source \( m_1 \circ_1 \) or \( m_2 \circ_2 \) as a spacetime worldline. Then each diagram in the post-Minkowskian expansion (2.6) becomes made of concatenated propagators, with some propagators starting on the worldlines, and intermediate propagators joining either a gravitational vertex, or a worldline. We shall later give explicit examples of such spacetime representations of effective-action diagrams, which generalize the representation used by Fokker himself back in 1929.

\footnote{The explicit coefficients shown in Eq. (2.6) above follow from the specific \( S_{\text{eff}}[\varphi] = \frac{1}{2} \mathcal{V}_{\varphi}[\varphi_{\circ}] \) vertex normalization chosen in [28]. When absorbing the conventional prefactor \( \frac{1}{\hbar} \) in the definition of the vertex \( \mathcal{V}_{\varphi} \), many of the factors in the effective action (2.6) become unity, and the remaining ones are usual symmetry factors.}
When further taking the PN expansion of the time-symmetric (scalar) propagator, say
\[ G(t, x; t', x') = -4\pi \left( \Delta - \frac{1}{c^2} \partial_t^2 \right)^{-1} \]
\[ = -4\pi \left( \Delta^{-1} + \frac{1}{c^2} \Delta^{-2} \partial_t^2 + \frac{1}{c^4} \Delta^{-3} \partial_t^4 + \cdots \right) \delta(t - t'), \]  
(2.7)
each post-Minkowskian diagram in the expansion (2.6) will generate a sequence of PN-type diagrams (involving inverse powers of the Laplacian, together with time-derivatives, as propagators). These are now three-dimensional (or d-dimensional) diagrams made of PN-propagators \( \Delta^{-n} \) connecting the two point masses \( m_1\delta(x - x_1) \) and \( m_2\delta(x - x_2) \) via some intermediate field points that are integrated over. It has been known for a long time that the computation of the effective action at the nPN level involves diagrams whose topology features \( \leq n \) loops. The topological loops can be recognized either on the spacetime diagrams, or on the projections as d-dimensional diagrams. For instance, Fig. 1 in Ref. [32] represents a spatial, two-point, three-loop diagram representing a 3PN-level contribution \( O(G^3m_1m_2^3) \) to the effective ADM action of two point masses. Below, we shall give examples (with four loops, at the 4PN level) of such spatial diagrams.

Summarizing: the usual, Fokker-like computation of the PN-expanded gravitational action (using either harmonic coordinates, or ADM coordinates, and using either traditional methods or the field-theory-diagrammatic technique of [28]) leads to a sum of x-space integrals involving the concatenation of PN-propagators \( \Delta^{-n} \partial_t^{n+1} \delta(t - t') \) and their joining at intermediate spatial points, with vertices involving two derivatives (because of the structure of the gravitational action \( \partial\partial hh + \partial\partial hh \cdots \)).

The main points we wanted to emphasize here about the traditional Fokker-like computation of the effective action are: (i) all the contributions of the effective action are explicitly real; (ii) all the integrals are in x-space; (iii) all the integrations by parts used to reduce integrals to some “master” integrals are done in x-space; (iv) at each stage of the calculation one keeps track of the numerical coefficients multiplying each integral, because they are directly furnished by the replacement \( g_{\mu\nu}(x) \to \delta_{\mu\nu}[x, s(x)] \) of the gauge-fixed solution in (essentially) the Einstein-Hilbert Lagrangian (be it in harmonic guise, or in the ADM one).

By contrast, the EFT approach to the effective action is based on expanding functional integrals of the type (here written, for pedagogical purposes, as a scalar toy-model, with a source \( s(x) \), taken simply as a linear coupling here),
\[ e^{\pi S_{\text{eff}}} = \int D\varphi e^{\frac{\pi}{2} \left( \frac{\varphi^2}{\pi} \right)} \]
instead of expanding around the saddle point of the exponent (as done in the usual Fokker approach) one expands the functional integral around the Gaussian approximation defined by the free term with kinetic operator \( \mathcal{K} \), and with elementary contraction given by
\[ \langle \varphi(x)\varphi(y) \rangle = \int D\varphi e^{\frac{\pi}{2} \left( \frac{\varphi^2}{\pi} \right)} \varphi(x)\varphi(y) = i\hbar \mathcal{K}^{-1}_{x,y}, \]
(2.9)
where \( \mathcal{K}^{-1}_{x,y} \) denotes the inverse of the kinetic operator (i.e. a Green’s function). One then expands the exponent on the rhs of (2.8),
\[ \int D\varphi e^{\frac{\pi}{2} \left( \frac{\varphi^2}{\pi} \right)} \sum \frac{(i/\hbar)^n}{n!} \left( \varphi(x) + g\varphi^3 + \cdots \right)^n \]
(2.10)
applying Wick’s theorem to compute all the \( \varphi \) contractions arising from the various powers \( i^n \left( \varphi s + g\varphi^3 + \cdots \right)^n/n! \) coming from the expansion of the exponential. (We henceforth set \( \hbar = 1 \) for simplicity.) The lowest-order contribution comes from the term quadratic in \( s \), namely \( \frac{s^2}{2} \left( \int d\varphi \varphi(x)s(x) + \int d\varphi \varphi(y)s(y) \right) = \frac{s^2}{2} \int dxdy \mathcal{K}^{-1}_{x,y}(s(x)s(y)). \)
Factoring one power of \( i \) this contributes \( \frac{i^2}{2} \int dxdy \mathcal{K}^{-1}_{x,y}(s(x)s(y)) = -\frac{1}{2} \int dxdy \mathcal{K}^{-1}_{x,y}(s(x)s(y)), \) to the effective action \( S_{\text{eff}} \). This indeed coincides with the (correctly normalized) one-quantum exchange energy denoted \( -\frac{1}{2}I \) above.

Summarizing: the quantum, Feynman-like computation of the PN-expanded gravitational action deals with a sum of Wick contractions from the powers of the interaction terms \( \varphi s + g\varphi^3 + \cdots \) in the original field + particle action. This calculation involves many imaginary units \( i \). Because of a certain quantum tradition, these calculations have been done in \( p \)-space, rather than in x-space, using, e.g., elementary field contractions \( \langle \varphi\varphi \rangle = i/(\pi p^2) \) if the kinetic term is \( \Box \). (We use the mostly plus signature.) In this approach one has to take care of correctly multiplying each diagram by the needed symmetry factor (which can be somewhat tricky when considering high-order contractions). In doing the explicit calculations at the nth PN order, there appear diagrams having up to \( n \)-loops, corresponding to integrating over \( n \) independent loop momenta variables. [Note that though the Fourier-space integrals to compute are in one-to-one correspondence (modulo an overall Fourier transform) with the x-space ones which enter the other approach, the computations are somewhat different, and the number of integrations to perform over intermediate points in the x-space approach is generally not equal to the number of topological loops in the diagram.]

Let us discuss the equivalence between the two approaches in further detail, and also emphasize why it is useful to define the Green’s function \( G(x, y) \) associated with the kinetic operator \( \int \frac{1}{2} \phi K\phi \) as being minus the inverse of the kinetic term, say
\[ K G(x, y) = -\delta(x - y). \]
(2.11)
This was the convention of [28], and it leads, when coupling the field to a source \( s(x) \), (i.e. \( \int \frac{1}{2} \phi K\phi + \phi s + g\phi^3 + \cdots \)).
of the effective action in powers of the source
where the needed integrations over intermediate space-
where the needed integrations over intermediate space-
give the same result, (2.16), for the logarithm of
From the above reasoning, it is guaranteed that this will
approximating an integral of the type
The essential point is that we have two different ways of
approximating an integral of the type
\[ \int D\phi e^{\frac{1}{\hbar}S_{\text{eff}}}[f(\frac{1}{2}\phi K\phi + \varphi s + \gamma s^3 + \ldots)] \]
for the logarithm of \( S_{\text{eff}} \).

\[ \mu \rho \] to a leading-order effective action equal to
\[ + \frac{1}{2} \int s(x)G(x,y)s(y) \] Actually, the usefulness of the
minus sign in the Green’s function definition (2.11) is hidden
in the usual “quantum” definition (2.9) of the elementary
contraction of the field \( \varphi \). Indeed, the rhs of Eq. (2.9) is
really \(-\left(\frac{\hbar}{2}\right)^{-1}\), i.e. minus the inverse of the operator
appearing in the exponent of the (functional) integral that
one is dealing with. In other words, the imaginary units
\( i \) that crowd up the EFT computations are irrelevant.

The essential point is that we have two different ways of
approximating an integral of the type
\[ Z[s] = e^{\frac{1}{\hbar}S_{\text{eff}}} = \int D\varphi e^{\frac{1}{\hbar}(f(\frac{1}{2}\varphi K\varphi + \varphi s + \gamma s^3 + \ldots))} \]
(2.12)
where \( \mu \) is a formal small parameter, and where the
functional measure is normalized so that \( Z[s = 0] = 1 \). As
the perturbative calculation of \( S_{\text{eff}} = \mu \ln Z[s] \) is a purely
algebraic matter, one can replace the quantum “small
parameter” \( \frac{1}{2} \) by any formally small parameter \( \mu \). One
can even simplify the writing by assuming that the small
parameter is absorbed in the definition of the quadratic
form \( \varphi K\varphi \), and of the interaction terms. Doing so, the
classical approximation to the integral (2.12) is to use the
saddle-point approximation
\[ Z[s] \approx e^{f(\frac{1}{2}\varphi K\varphi + \varphi s + \gamma s^3 + \ldots)} \]
(2.13)
where \( \varphi_s \) is the saddle point, i.e. the solution of
\[ 0 = \delta \left[ \frac{1}{2} \varphi K\varphi + \varphi s + \gamma \varphi^3 + \ldots \right] / \delta \varphi \]
\[ = \varphi \, K \varphi + s + 3 \gamma \varphi^2 + \ldots \]
(2.14)
In this approach, one solves the saddle point condition
(2.14) by a perturbative series away from the unperturbed
solution \( \varphi = 0 \), namely [with \( K = -\mathcal{G}^{-1} \) according to
the definition (2.11)]
\[ \varphi_s = \mathcal{G}s + \mathcal{G}(3g(\mathcal{G}s)^2) \ldots \]
(2.15)
where the needed integrations over intermediate space-
time points are left implicit. This leads to an expansion of
the effective action in powers of the source \( s \):
\[ S_{\text{eff}}[s] \approx \ln Z[s]_{\text{saddle}} \approx \frac{1}{2} s \mathcal{G}s + g(\mathcal{G}s)^3 + \ldots \]
(2.16)
In the other, Feynman-like approach one approximates
(at the exponential accuracy) the integral (2.12) by
expanding the integrand away from the Gaussian term
\[ Z[s] = \int D\varphi e^{\frac{1}{\hbar}(f(\frac{1}{2}\varphi K\varphi + \varphi s + \gamma s^3 + \ldots))} \]
(2.17)
using the elementary contraction
\[ \langle \varphi(x)\varphi(y) \rangle = \mathcal{G}_{x,y}^{-1} = \mathcal{G}(x,y) \]
(2.18)
From the above reasoning, it is guaranteed that this will
give the same result, (2.16), for the logarithm of \( Z[s] \).

But this reasoning shows that all the \( i \)'s are a useless
complication (which can easily lead to sign errors when
there are many of them), as we are computing a real
effective action (when using the time-symmetric Green
function appropriate to describing the conservative
dynamics).

III. EXPLICIT EXPRESSIONS OF THE
RELEVANT FOUR-LOOP, 4PN EFFECTIVE-ACTION CONTRIBUTIONS

We focus, in this paper, on the few effective-action contribu-
tions that Ref. [22] emphasized as being potentially
problematic. As explained in [22] these terms are purely
“static” and follow from the simplified particle + field
action
\[ S = S_{\text{pm}} + S_{\text{field}} \]
(3.1)
where the (static) point-mass action is
\[ S_{\text{pm}} = - \sum_a m_a \int dt e^{\lambda \phi} \]
\[ = - \sum_a m_a \int dt (1 + \lambda \phi + \ldots) \]
(3.2)
and where the field action [22, 35] is
\[ S_{\text{field}} = \int d^4x \sqrt{\gamma} \left[ \frac{1}{4} \epsilon^{ij,k\ell,mn} (\partial_i \sigma_{kl} \partial_j \sigma_{mn} \right. \]
\[ - 2 \partial_i \sigma_{km} \partial_j \sigma_{ln} - c_{ij} \partial_i \phi \partial_j \phi \]
\[ + \lambda \left( \sigma_{ij} - \frac{1}{2} \sigma \delta_{ij} \right) (\partial_{ik} \partial_j \sigma_{ij} - \sigma_{ik} \partial_{ij} \sigma_{ij} \right. \]
\[ + \sigma_{ij} (\partial_{ik} \partial_j \sigma_{ij} - \sigma_{ik} \partial_{ij} \sigma_{ij}) \]
(3.3)
Here, we followed the notation of [22], apart from the fact
that we use \( \lambda = 1/\Lambda = \sqrt{32\pi G}\rho_a^{-3} \). The gravitational
field degrees of freedom are described by \( \phi \) and \( \sigma_{ij} \), with
\( \gamma_{ij} = \delta_{ij} + \lambda \sigma_{ij} \). In addition, \( c_{ij} \equiv \frac{\lambda}{2+\lambda} \gamma = \det \gamma_{ij} \),
\( \sigma = \sigma_{ii} \), and \( f_{ij} \equiv \partial_i \sigma_{jj} \). Note that, in this approximation,
only \( \phi \) is directly coupled to the particles. The tensor
field \( \sigma_{ij} \) is only excited through the cubic vertex following
from the kinetic term of \( \phi \):
\[ - c_d \sqrt{\gamma} \gamma^{ij} \partial_i \phi \partial_j \phi \]
\[ = - c_d \left( \delta_{ij} - \lambda \sigma_{ij} + \frac{1}{2} \lambda \sigma \delta_{ij} + O(\sigma^2) \right) \partial_i \phi \partial_j \phi \]
(3.4)
For the four-loop terms we are interested in, only the
linear coupling of \( \phi \) to the particles,
\[ \int d^4x \phi(x)s(x) \equiv - \sum_a m_a \lambda \phi(x_a) \]
(3.5)
matters. Here the Lagrangian density of the source is

\[ s(x) = -\lambda m_1 \delta_1 - \lambda m_2 \delta_2, \quad (3.6) \]

where \( \delta_s \equiv \delta(x - x_a) \).

We can then describe the algebraic structure of the relevant particle + field Lagrangian as

\[ \mathcal{L} = \mathcal{L}_0 + \epsilon \mathcal{L}_1, \quad (3.7) \]

where

\[ \mathcal{L}_0 = -\frac{1}{2} \phi^2 - \frac{1}{2} \phi^2 + \phi s + a\sigma \phi^2 \quad (3.8) \]

includes the kinetic terms, the linear coupling to matter, and the cubic vertex between \( \sigma_{ij} \) and \( \phi \) coming from the \( \phi \) kinetic term (3.4), namely

\[ a\sigma \phi^2 = \mathcal{L}_{\text{cubic}} = \lambda c_d \left( \sigma_{ij} - \frac{1}{2} \sigma \delta_{ij} \right) \partial_i \phi \partial_j \phi. \quad (3.9) \]

[Note that, following Eq. (2.11), we have expressed the kinetic operators of \( \phi \) and \( \sigma \) in terms of the corresponding Green’s functions \( \mathcal{G}_\phi, \mathcal{G}_\sigma \).] The remaining, higher-order terms in the relevant 4PN action have the algebraic structure

\[ \epsilon \mathcal{L}_1 = b \sigma^2 \phi^2 + c \sigma^3. \quad (3.10) \]

They respectively correspond to the \( O(\sigma^2) \partial_i \phi \partial_j \phi \) terms in the \( \phi \) kinetic term (3.4), and to the sum of the last line in the field action (3.3), and of the terms coming from the kinetic terms of \( \sigma_{ij} \) when considering the terms of order \( \lambda \sigma \). in the expansion of

\[ \sqrt{\gamma} \gamma_{ijkl} \gamma^{mn} = \delta_{ij} \delta_{kl} \delta_{mn} + O(\lambda \sigma), \quad (3.11) \]

using \( \sqrt{\gamma} = 1 + \frac{1}{2} \lambda \sigma + O(\lambda^2), \quad \gamma^{ij} = \delta_{ij} - \lambda \sigma_{ij} + O(\lambda^2). \)

Hence,

\[ c \sigma^3 = \frac{1}{4} O(\lambda \sigma)_{ijklmn} \partial_i \sigma_{jkl} \partial_m \sigma_{mn} - 2 \partial_i \sigma_{km} \partial_j \sigma_{ln} \]

\[ + \lambda \left( \sigma_{ij} - \frac{1}{2} \sigma \delta_{ij} \right) \left( \sigma_{ik,klm} - \sigma_{ik,m} \sigma_{jl,lm} \right) \]

\[ + \sigma_{i,j,k,l,m} - \sigma_{i,j,k} \sigma_{l,m}. \quad (3.12) \]

As for the terms \( b \sigma^2 \phi^2 \), they are explicitly given by

\[ b \sigma^2 \phi^2 = -cd \left[ \sqrt{\gamma} \gamma^{ij} \right]_{\sigma^2} \partial_i \phi \partial_j \phi, \quad (3.13) \]

with

\[ \left[ \sqrt{\gamma} \gamma^{ij} \right]_{\sigma^2} = \lambda^2 \left( \frac{1}{8} \sigma^2 \delta_{ij} - \frac{1}{4} \sigma_{kl} \delta_{ij} \right) \]

\[ - \frac{1}{2} \sigma \sigma_{ij} + \sigma_{ik} \sigma_{jk}. \quad (3.14) \]

The saddle-point conditions (of field equations of motion) for \( \phi \) and \( \sigma \) have the structure

\[ -\frac{\phi}{\mathcal{G}_\phi} + s + 2a\sigma \phi + \epsilon \frac{\delta \mathcal{L}_1}{\delta \phi} = 0, \quad (3.15) \]

\[ -\frac{\sigma}{\mathcal{G}_\sigma} + a\phi^2 + \epsilon \frac{\delta \mathcal{L}_1}{\delta \sigma} = 0. \quad (3.16) \]

As the solution of these field equations of motion is only needed for being replaced in the Lagrangian \( \mathcal{L}(\phi, \sigma, s) \), it is well-known that it is enough to solve the equations of motion coming from \( \mathcal{L}_0 \), i.e. to take \( \epsilon = 0 \) in the above field equations. Indeed, as \( \delta \mathcal{L}/\delta \text{field} = 0 \), the corrections to the field solution coming from \( \epsilon \mathcal{L}_1 \) contribute only at order \( \epsilon^2 \) to the Fokker action. (It is essentially this basic fact that, upon the suggestion one of us (TD), was used to simplify the recent 4PN harmonic-coordinates computation of the Fokker action [21].) To lowest-order in a non-linear expansion in the source [i.e. in an expansion in powers of the two masses \( m_1, m_2 \), see (3.6)], we immediately see that the solutions of the above field equations are

\[ \phi_* = \mathcal{G}_\phi s + O(s^2), \quad (3.17a) \]

\[ \sigma_* = \mathcal{G}_\sigma (a \phi_*^2) + \cdots = \mathcal{G}_\sigma (a (\mathcal{G}_\phi s)^2) + O(s^3). \quad (3.17b) \]

From the above reasoning, we deduce the first result that the contribution of the action correction \( \epsilon \mathcal{L}_1 \) to the effective (Fokker) action is simply obtained by replacing in \( \epsilon \mathcal{L}_1 \) the fields \( \phi \) and \( \sigma \) by their lowest-order solution (because this is enough to get \( \epsilon \mathcal{L}_1 \) to order \( s^2 \)), namely

\[ \epsilon \mathcal{L}_{1\text{eff}}^\phi = \left[ b \sigma^2 \phi^2 + c \sigma^3 \right]_{\sigma = \mathcal{G}_\phi s} (a (\mathcal{G}_\phi s)^2). \quad (3.18) \]

This result takes care of two of the contentious action contributions highlighted by [22], namely \( L_{33} \), linked to \( b \sigma^2 \phi^2 \), and \( L_{50} \), linked to \( c \sigma^3 \), and allows one to compute them straightforwardly (including all numerical factors). The remaining contentious action contribution, \( L_{49} \), is easily seen (from its diagram in Fig. 1 of [22]; see also below) to arise from the exchange of two cubic vertices, (3.9). Therefore, in a Fokker-type calculation, this term arise from solving the field equations of motion Eqs. (3.15), (3.16) to fourth order in the \( \phi-\sigma \) coupling (3.9), that we had left in the zeroth-order action \( \mathcal{L}_0 \).

It is fairly easy to solve Eqs. (3.15), (3.16) (without the \( \epsilon \mathcal{L}_1 \) terms) to order \( O(a^4) \). First, let us note that we are talking here about a purely algebraic calculation that could be done by iterating polynomial expressions. The aim of our calculation is to get the correct numerical coefficient in front of the \( O(a^4) \) Fokker action contribution. This can be formally done by solving Eqs. (3.15), (3.16) as if \( \phi \) and \( \sigma \) were ordinary numbers. As Eq. (3.15) (without the \( \epsilon \mathcal{L}_1 \) term) is linear in \( \phi \) we can solve \( \phi \) in terms of \( \sigma \) and replace the answer in the second equation. Denoting

\[ x = a \mathcal{G}_\phi \sigma, \quad x_0 = a^2 \mathcal{G}_\sigma \mathcal{G}_\phi^{-1} x^2, \quad (3.19) \]

the solution of Eq. (3.15) reads \( \phi(\sigma) = (1 - 2x)^{-1} \mathcal{G}_\phi s \), and its insertion in Eq. (3.16) (without the \( \epsilon \mathcal{L}_1 \) term) reads

\[ x(1 - 2x)^2 = x_0. \quad (3.20) \]
This is easily solved by iteration in powers of the source:
\[ x = x_0(1 + 4x_0 + O(x_0^2)) \]  
(3.21)

Inserting this solution in \( \mathcal{L}_0 \) then easily leads to an expansion in even powers of \( s \):
\[ \mathcal{L}^{\text{eff}}[s] = \frac{1}{2}G_\phi s^2 + \frac{1}{2}a^2 G_\sigma G_\phi s^4 + 2a^4 G_\sigma^2 G_\phi^2 s^6 + O(s^8). \]  
(3.22)

Here, we are interested in the third term of order \( s^6 \), i.e. involving six masses. The aim of the above algebraic calculation was to safely derive the numerical factor in front of this contribution (which is linked to \( L_{\text{eff}} \)). It is easy to understand which diagram this term is connected with by rewriting it as (denoting the linear-in-source solution as \( \phi_1 \equiv G_\phi s \)):
\[ \frac{1}{2}[2a[\alpha G_\sigma (\phi_1^{(1)})^2] \phi_1^{(1)}] \mathcal{G}_[\sigma] [2a[a G_\sigma (\phi_1^{(1)})^2] \phi_1^{(1)}], \]  
(3.23)

where the nested brackets on each side (starting with \([2a[\cdots]\cdots]) denote the third-order (in \( s \)) solution of the \( \phi \) equation, i.e. the second term, \( \phi_1^{(2)} \), in
\[ \phi_s = \phi_1^{(1)} + \phi_1^{(2)} = G_\phi s + G_\phi [2a[a G_\sigma (\phi_1^{(1)})^2] \phi_1^{(1)}] \]
\[ = G_\phi s + G_\phi [2a a \sigma_2 G_\sigma (\phi_1^{(1)})^2] \phi_1^{(1)}, \]  
(3.24)

where
\[ \sigma_2^2 = \frac{\mathcal{G}_\sigma [\alpha (\phi_1^{(1)})^2]}{(4.3)} \]  
(3.25)

denotes the lowest-order (quadratic in \( s \)) solution for \( \sigma \), obtained by inserting \( \phi_1^{(1)} \) in the effective source \( a \sigma^2 \) of \( \sigma \) [see Eq. (4.14)]. The diagrammatic representation of this \( O(a^4 s^6) \) contribution to the effective action is displayed in Fig. 1.

A useful way of reexpressing the \( O(a^4 s^6) \) contribution to \( \mathcal{L}^{\text{eff}}[s] \) is to write it as
\[ \mathcal{L}^{\text{eff}}[s]_{s \phi} = \frac{1}{2} \left[ \frac{\delta \mathcal{L}_{\text{cubic}}}{\delta \phi} \right] \phi_2^{(3)} \]  
(3.26)

where \( \mathcal{L}_{\text{cubic}} = a \sigma \phi^2 \) is the cubic \( \sigma - \phi \) coupling, Eq. (3.9), and where all the fields in \( \delta \mathcal{L}_{\text{cubic}} / \delta \phi = 2a \sigma \phi \) on the rhs can be replaced by their lowest-order solutions.

### IV. EXPLICIT COMPUTATION OF THE CONTENTIOUS FOUR-LOOP, 4PN EFFECTIVE-ACTION CONTRIBUTIONS

We have given in the preceding section all the material needed to write down, in \( x \)-space, all the integrals \( L_{26} \) to \( L_{50} \) in Fig. 1 of Ref. [22], i.e. all the \( O(s^8) \) diagrams where the \( \phi \) field couples only linearly to the particles. [The other \( O(s^6) \) diagrams \( L_1 \) to \( L_{25} \) in Fig. 1 of Ref. [22] all involve some \( \phi^n s \) coupling with \( n \geq 2 \)].

Among the integrals \( L_{26} \) to \( L_{50} \), we are only interested in reevaluating the three integrals \( L_{33}, L_{49} \) and \( L_{50} \), which contain the transcendental coefficient \( \zeta(2) = \pi^2/6 \), and whose evaluations in Ref. [22] gave the problematic values \( [1, 0] \). The method of computation used in Ref. [22] was the Feynman-like one sketched above: in \( p \)-space, with purely imaginary propagators \( iK^{-1} \), and with the usage of integration by parts identities to reduce the multi-loop \( p \)-space integrals to a subset of master integrals [one of them, \( M_{3, n} \), could only be evaluated numerically, though with such a high accuracy that they could recognize the presence of \( \zeta(2) = \pi^2/6 \) in it].

In the following three subsections we shall reevaluate the four-loop integrals \( L_{33}, L_{49} \) and \( L_{50} \), in \( x \)-space, using \( x \)-space integration by parts, and using as master integrals only the ones that have been used in our previous PN (and ADM) work, namely the original Riesz integration formula [30] [which was crucially used in the first complete computation of the (harmonic-coordinates) 2PN action (containing up to two-loop diagrams) [8, 37], together with the ‘generalized Riesz formula’ (first derived in Ref. [27] for the computation of the 3PN Hamiltonian, and which was also sufficient for the computation of the local ADM 4PN Hamiltonian computation [10]).

To streamline the presentation of our computations, we will relegate most of the needed, general integration formulas to Appendix A.

#### A. \( L_{33} \)

In \( x \)-space, \( L_{33} \) arises (together with its cousins \( L_{26}, L_{27}, L_{28}, L_{29}, L_{30}, L_{31}, L_{32}, \) and \( L_{34} \) in Fig. 1 of Ref. [22]) from an integral of the form
\[ L_{33, \sigma} = \int dx \, \sigma \phi \phi \]  
(4.1)

in which \( \phi \) and \( \sigma \) must be replaced by their lowest-order solutions, denoted \( \phi_1^{(1)} \) and \( \sigma_2^{(2)} \) above, so that \( L_{33, \sigma} \phi \) is of sixth order in the masses. The explicit expression of the integrand \( \sigma \phi \phi \phi \phi \) is obtained from inserting Eq. (3.14) in Eq. (3.26), and reads
\[ \sigma \phi \phi \phi \phi = -\lambda^2 c_{\phi} \left( \frac{1}{8} \sigma^2 \delta_{ij} - \frac{1}{4} \sigma_k \delta_{ij} \phi \right) \]  
(4.2)

When decomposing \( \phi_1^{(1)} \) and \( \sigma_2^{(2)} \) according to their mass content, i.e.
\[ \phi_1^{(1)} = m_1 \phi_1 + m_2 \phi_2. \]  
(4.3)
and

\[ \sigma^{(2)}_{ij} = m^2_1 \sigma_{11} + m_1 m_2 \sigma_{12} + m^2_2 \sigma_{22}, \quad (4.4) \]

one recovers all the diagrams \( L_{26} \) to \( L_{27} \) (modulo some vanishing self-gravity ones, and the 1 \( \leftrightarrow \) 2 images of the previous ones).

But we are only interested in \( L_{33} \), given by the spacetime diagram Fig. 2 (The thin lines represent the \( \phi \) propagators, while the wavy lines represent the \( \sigma \) propagators.) The \( d \)-dimensional projection of the diagram of \( L_{33} \) is the two-point, four-loop diagram Fig. 3 (Here, the empty circles represent the two point-mass sources, i.e. the spatial projections of the thick, external worldlines in the corresponding spacetime diagram.) We see on its representation that this diagram (modulo the convention \( L_{\text{FMSS}} = \frac{1}{2} L_{\text{here}} \)) is obtained from the general integral \( L_{\sigma \phi \phi \phi} \) by replacing each \( \sigma \) by \( m_1 m_2 \sigma_{12} \), and one \( \phi \) by \( m_1 \phi_1 \) and the other by \( m_2 \phi_2 \), so that

\[ L_{33} = 2 m_1^3 m_2^3 L_{\sigma \sigma_{12} \phi_1 \phi_2}, \quad (4.5) \]

the factor 2 taking into account the two possibilities \( \phi_1 \phi_2 \) vs \( \phi_2 \phi_1 \).

We explained in Sec. III above the definitions of \( \phi^{(1)} \) and \( \sigma^{(2)} \) in terms of sources and propagators. In practical terms, the consideration of the Euler-Lagrange equations defined by the action (3.3) yields

\[ \Delta \phi = \frac{\lambda}{2 c_d} \sum_a m_a \delta_a + \cdots, \quad (4.6) \]

so that (using standard \( d \)-dimensional formulas recalled in Appendix A)

\[ \phi^{(1)} = \frac{k}{4 \pi} \frac{\lambda}{2 c_d} \sum_a m_a r_a^{2-d}, \quad (4.7) \]

where \( r_a \equiv |x - x_a| \).

Writing the field equation for \( \sigma_{ij} \) following from the action (3.3) yields (after a simple manipulation)

\[ \Delta \sigma_{ij} = -\lambda c_d \partial_i \phi \partial_j \phi + \cdots, \quad (4.8) \]

so that

\[ \sigma^{(2)}_{ij} = -\lambda c_d \Delta^{-1}[\partial_i \phi^{(1)} \partial_j \phi^{(1)}]. \quad (4.9) \]

In particular, we see that the mixed contribution \( m_1 m_2 \sigma_{12} \) to \( \sigma^{(2)}_{ij} \) can be expressed (in \( x \)-space) in terms of partial derivatives (with respect to \( x_1 \) and \( x_2 \)) of the \( d \)-dimensional potential \( g_d \) defined by

\[ g_d(\mathbf{x}, x_1, x_2) = \Delta^{-1}(r_1^{2-d} r_2^{2-d}). \quad (4.10) \]

An explicit expression for \( g_d(\mathbf{x}, x_1, x_2) \) was derived in Appendix C of [38]. Let us only recall now that, when \( \varepsilon = d - 3 \to 0 \), one has the formal result

\[ g_d = -\frac{1}{2 \varepsilon (1 - \varepsilon)} + \ln \left( \frac{r_1 + r_2 + r_{12}}{2} \right) + O(\varepsilon), \quad (4.11) \]

so that one recovers the well-known fact (originally due to Fock) that, in three dimensions,

\[ g_3 = \frac{1}{2} \ln \left( \frac{r_1 + r_2 + r_{12}}{2} \right) \quad (4.12) \]

is a solution of \( \Delta g_3 = r_1^{-1} r_2^{-1} \). (It will be convenient in the following to include the factor \( \frac{1}{2} \) in the argument of the logarithm.)

In three dimensions, the explicit expression of \( \sigma_{12} \) is

\[ \sigma_{12} = -\frac{1}{(4\pi)^2} \frac{\lambda^3}{16} \left( \partial^2_i \partial^2_j \tilde{g}_3 + \partial^2_i \partial^2_j \tilde{g}_3 \right). \quad (4.13) \]

where \( \partial^a_i \equiv \partial / \partial x^a_i (a = 1, 2) \), while the functions \( \phi_a \) (a = 1, 2) read

\[ \phi_a = -\frac{\lambda}{32\pi} \frac{1}{r_a}. \quad (4.14) \]

It is then easily seen that, in \( d = 3 \), the integral \( L_{33} \) is convergent both in the ultraviolet (UV), i.e. near the point masses, and in the infrared (IR), i.e. at spatial infinity.

In three dimensions the integrand of \( L_{33} \) [see Eq. (4.5) together with Eqs. (4.11)-(4.12) and (4.13)-(4.14)] can be explicitly written as
\[
\frac{\lambda^0 m_1^2 m_2^3}{(16\pi)^6} \frac{[(r_1 - r_2)^2 - r_{12}^2][(r_1 - r_12)(r_1 + r_12)^3 - 2r_{12}^2 r_2 - 2r_{12}^2 r_2^2 + 2r_{12}r_2^3 + r_2^4]}{2r_1^2 r_{12}^2 (r_1 + r_2 + r_12)^2},
\]

(4.15)

in which \(\phi\) and \(\sigma\) must be replaced by their lowest-order solutions, denoted \(\phi^{(1)}\) and \(\sigma^{(2)}\) above. From the form of the diagram of \(L_{49}\) one sees that one must keep in \(\omega\) only the two pieces generated by \(m_1 m_2 \sigma_{12}\) and bilinear in the two pieces of \(\phi^{(1)} = m_1 \phi_1 + m_2 \phi_2\). Defining

\[
\omega_{a}^{12} \equiv \partial_i \left( \sigma_{ij}^{12} - \frac{1}{2} \sigma^{12} \delta_{ij} \right) \partial_j \phi_a,
\]

(4.19)

where, for clarity, we put the mass labels 12 of \(\sigma\) as superscripts, we end up with

\[
L_{49} = -2 \lambda^2 c_d m_1^3 m_2^3 \int d^d x \omega_a^{12} \Delta^{-1} \omega_a^{12},
\]

(4.20)

where the extra factor 2 takes into account the two orderings \(\omega_a^{12} \omega_b^{12} \neq \omega_b^{12} \omega_a^{12}\).

The integral \(L_{49}\) is IR convergent, but it has a mildly singular UV behavior because of the presence of two derivatives of \(\phi_a\) in \(\omega_a^{12}\) (when expanding its definition (4.19)). One must treat these derivatives in a distribution-theory way. After evaluating all differentiations present in \(\omega_1^{12}\) one gets (in \(d = 3\))

\[
\omega_1^{12} = \omega_1^{12 \text{fun}} + \omega_1^{12 \text{DD}},
\]

(4.21)

where

\[
\begin{align*}
\omega_1^{12 \text{fun}} &= -\frac{\lambda^4}{(16\pi)^3} \frac{3}{4} \left( \frac{r_{12}}{r_2} - \frac{2r_2}{r_{12}} + \frac{r_{12}^2}{r_1} \right) \frac{1}{r_1^2} \\
&\quad - \frac{1}{2} \left( \frac{1}{r_2} - \frac{2}{r_{12}} + \frac{r_{12}^2}{r_1} \right) \frac{1}{r_1^2} - \frac{r_{12}}{r_{12}^2 r_2^2}, \\
&\quad + \frac{1}{2r_{12}^2 r_1^2} + \frac{1}{4r_{12}^2 r_2^2},
\end{align*}
\]

(4.22a)

\[
\omega_1^{12 \text{DD}} = -\frac{\pi}{3r_{12}} \frac{\lambda^4}{(16\pi)^3} \delta_1.
\]

(4.22b)

It is not difficult to find the function \(\chi_1\) such that \(\Delta \chi_1 = \omega_1^{12 \text{fun}}\) in the sense of distributions. It reads

\[
\chi_1 = \frac{\lambda^4}{(16\pi)^3} \left[ \frac{r_2}{r_{12}} - \frac{r_{12}^2}{r_1} \right] \frac{1}{r_1^2}
\]

(4.23)

\[
+ \frac{1}{4} \left( \frac{r_{12}^2}{r_1} - \frac{r_2}{r_{12}} \right) \frac{1}{r_1^2} + \frac{r_{12}}{4r_{12}^2 r_2^2}.
\]

(4.23)

Computation of \(\Delta \chi_1\) in the sense of distributions gives extra distributional terms

\[
\Delta \chi_1 = \omega_1^{12 \text{fun}} + \frac{\lambda^4}{(16\pi)^3} \left( \frac{2\pi}{3r_{12}} \delta_1 - \frac{2\pi}{r_{12}} n_{12} \cdot \nabla \delta_1 \right).
\]

(4.24)
Hence, in the sense of distributions,
\[
\Delta \left[ \chi_1 + \frac{\lambda^4}{(16\pi)^3} \left( \frac{1}{6r_1^2} \frac{1}{r_1} - \frac{1}{2r_{12}} \mathbf{n}_{12} \cdot \nabla \frac{1}{r_1} \right) \right] = \omega_{1 \text{fun}}^{12},
\]
(4.25)

\[
\Delta^{-1} \omega_{1}^{12} = \chi_1 + \frac{\lambda^4}{(16\pi)^3} \left( \frac{1}{6r_1^2} \frac{1}{r_1} - \frac{1}{2r_{12}} \mathbf{n}_{12} \cdot \nabla \frac{1}{r_1} \right) + \Delta^{-1} \omega_{1 \text{DD}}^{12} \\
= - \frac{\lambda^4}{4(16\pi)^3} \left[ \left( 1 - \frac{r_2}{r_{12}} - \frac{r_2^2}{r_{12}^2} + \frac{r_2}{r_{12}} \right) \frac{1}{r_1} + \frac{1}{r_{12}} \left( \frac{r_2}{r_{12}} - \frac{r_2^2}{r_{12}^2} \right) \frac{1}{r_1} - \frac{r_2}{r_{12}} \frac{1}{r_1} \right].
\]
(4.26)

Making use of Eqs. (4.21), (4.22) and (4.26), the integrand of \(L_{49}\) can symbolically be written as
\[
\lambda^2 m_2^3 m_1^3 \omega_{1}^{12} \Delta^{-1} \omega_{2}^{12} \sim \frac{\lambda^{10} m_1^3 m_2^3}{(16\pi)^9} \sum_k d_k \frac{a_k}{r_1} \frac{b_k}{r_2} \frac{c_k}{r_{12}} \\
+ \frac{\lambda^{10} m_1^3 m_2^3}{(16\pi)^5} \sum_k d_k' a_k' b_k' c_k' \delta_1,
\]
(4.27)

where \(a_k, b_k, c_k\), \(a_k', b_k', c_k'\) are integers and the coefficients \(d_k\) and \(d_k'\) are rational numbers. The integral of the first part of (4.27) is evaluated by means of the (ordinary) Riesz formula while the integral of the second part is computed by using Hadamard partie finie procedure. Our final result is
\[
L_{49} = (64 - 6\pi^2) \frac{G^5 m_1^3 m_2^3}{c^6 r_{12}^3}.
\]
(4.28)

C. \(L_{50}\)

In \(x\)-space, \(L_{50}\) arises (together with its cousins \(L_{40}, L_{43}, L_{45}, \) and \(L_{46}\)) from the effective action contribution denoted \(\sigma^\text{corr}\) above, and defined in Eq. (3.12). The spacetime diagram of \(L_{50}\) is displayed in Fig. 6 while its (non-planar, two-point, four-loop) spatial projection is shown in Fig. 7.

Again the term \(L_{50}\) we are interested in is, as seen on its diagram, selected from this cubic expression in \(\sigma\) by replacing each occurrence of \(\sigma\) by its mixed piece \(m_1 m_2 \sigma_{12},\) i.e., symbolically
\[
L_{50} = m_1^3 m_2^3 \int d^4 x \; c (\sigma_{12})^3
\]
(4.29)

without any extra symmetry factor.

The integral \(L_{50}\) is both IR and UV convergent. In three dimensions its integrand can be symbolically written as
\[
\frac{\lambda^{10} m_1^3 m_2^3}{(16\pi)^5} \sum_k d_k \frac{a_k}{r_1} \frac{b_k}{r_2} \frac{c_k}{r_{12}},
\]
(4.30)

Taking this result into account as an inverse Laplacian of \(\omega_1\) we take

\[
\text{FIG. 6. The spacetime diagram of } L_{50}.\]

\[
\text{FIG. 7. The spatial projection of the diagram of } L_{50}.\]

where \(a_k, b_k, c_k\) are integers and the coefficients \(d_k\) are rational numbers. For evaluation of the integral \(L_{50}\) it is thus enough to use the generalized Riesz formula \(I[a, b, c] \) with \(c = -3.\) Our final result is
\[
L_{50} = \left( -\frac{248}{3} + 8\pi^2 \right) \frac{G^5 m_1^3 m_2^3}{c^6 r_{12}^3}.
\]
(4.31)

D. Total result, and comparison with Ref. [22]

The crucial result of our new computations is that the transcendental coefficients \(\sim \pi^2 \text{ cancel}\) in the sum of the three contributions \(L_{33}, L_{49},\) and \(L_{50}:
\[
L_{33} + L_{49} + L_{50} = \frac{40}{3} \frac{G^5 m_1^3 m_2^3}{c^6 r_{12}^3}.
\]
(4.32)

This cancellation comes about because, while our results for \(L_{33}\) and \(L_{49}\) agree with the corresponding results of
Ref. [22] recalled in Eq. (1.6) above, our result for $L_{50}$ differs from the corresponding result of Ref. [22] by a factor $-3$:

$$L_{50} = -3 L_{50}^{\text{FMSS}} = -6 L_{50}^{\text{FMSS}}. \quad (4.33)$$

It would be interesting to understand the origin of such a missing factor $-3$ in Ref. [22]. It might be caused by the presence of many $i\varepsilon$'s (including the ones linked to the Fourier transform of spatial derivatives $\partial_\nu \rightarrow i\varepsilon \partial_\nu$) in the quantum, $p$-space calculation of $S_{\text{eff}}$, together with an incorrect account of the pesky symmetry factors that enter any Wick-contraction calculation.

Anyway, we trust our result for $L_{50}$ because its normalization is very straightforwardly obtained in our $x$-space computation. It would be also important to know if the error in $L_{50}^{\text{FMSS}}$ has affected other integrals in Ref. [22]. (Because of the cancellation of all the pole parts $\sim 1/\varepsilon$ in the genuine $G^5$ contribution the cousins $L_{40}$, $L_{43}$, $L_{45}$, $L_{46}$ of $L_{50}$ cannot be uniformly affected by the same factor $-3$.)

Another reason for trusting our results is that they now reconcile the finding announced in Ref. [22] that all the currently known $\pi^2$-dependent coefficients at order $G^5$ in the harmonic-coordinates version of $L_{\text{eff}}^{\text{linear}}$ in $\nu_a$ come from the double-zero reduction of the quadratic-in-acceleration terms in the original $O(G^3)$ action, see Eq. (1.5). The correctness of the $O(m_1^2 m_2^2)$ sector of the harmonic-coordinates action of [17] was strongly expected in view of its agreement with the corresponding sector of the ADM action. [In terms of the $\mu$-reduced Hamiltonian, this corresponds to $O(\nu^2)$ terms that had been unambiguously derived already in Ref. [13].]

V. ANALYTIC COMPUTATION OF THE MASTER INTEGRAL $\mathcal{M}_{3,6}$

The master integral denoted $\mathcal{M}_{3,6}$ in Ref. [22] is the $d$-dimensional $p$-space, four-loop integral depicted in Fig. 8 and defined by

$$\mathcal{M}_{3,6}(p) \equiv \int \frac{dk_1 dk_2 dk_3 dk_4}{D_{3,6}}, \quad (5.1)$$

where $dk_i \equiv d^d k_i / (2\pi)^d$ are normalized Fourier integrals over the loop momenta, and where the denominator is

$$D_{3,6} = k_1^2 k_2^2 k_3^2 k_4^2 (k_2 - k_3)^2 (k_1 - k_4)^2$$

$$\times (k_1 + k_2 - p)^2 (k_1 + k_2 - k_3 - k_4 - p)^2. \quad (5.2)$$

Modulo some normalization factors, this is the Fourier transform of the following $d$-dimensional $x$-space integral

$$I_{u_1 u_2 g^2}^{(d)} \equiv \int d^d x \ u_1 \ u_2 \ (g_d)^2, \quad (5.3)$$

where

$$u_1 \equiv r_1^{2-d}, \quad u_2 \equiv r_2^{2-d}, \quad g_d \equiv \Delta^{-1}(u_1 u_2). \quad (5.4)$$

The diagrammatic representation (in $x$-space) of the (scalar, massless) two-point, four-loop integral (5.3) is displayed in Fig. 9. Note that both the $p$-space and $x$-space representations of this Feynman integral have the shape of a four-spoked wheel.

The basic reason why the four-loop integral (5.3) can be analytically computed near $d = 3$ by means of the generalized Riesz formula is seen in Eq. (4.11): near $d = 3$, $g_d \equiv \Delta^{-1}(u_1 u_2)$ contains the (Fock) function $\ln s$, where

$$s \equiv r_1 + r_2 + r_{12}. \quad (5.5)$$

Therefore, the integral (5.3) will contain (near $d = 3$) a sum of terms of the type $\int d^d x \ r_1^{-1} r_2^{-1} (\ln s)^2$ and $\int d^d x \ r_1^{-1} r_2^{-1} \ln s$, which can be obtained by differentiating the generalized Riesz formula with respect to the exponent of $s$. However, there are some tricky details when implementing such a computation of (5.3), as will be now explained.

First, one must cope with the IR-divergence of (5.1), or equivalently (5.3). This IR-divergence is rooted in the IR-divergence of $g_d$ itself, which shows up in the $1/\varepsilon$ contribution (where we recall $\varepsilon \equiv d - 3$) in Eq. (4.11). Let us define

$$C_0 \equiv \frac{1}{(2d - 6)(4 - d)} \equiv \frac{1}{2\varepsilon(1 - \varepsilon)} \quad (5.6)$$

and let us consider the new integral

$$I_{u_1 u_2 g^2}^{(d)} \equiv \int d^d x \ u_1 \ u_2 \ (\tilde{g}_d)^2, \quad (5.7)$$

where

$$\tilde{g}_d \equiv g_d + C_0. \quad (5.8)$$

The latter definition is such that $\tilde{g}_d$ has a (point-wise) finite limit in 3 dimensions, namely

$$\lim_{\varepsilon \to 0} \tilde{g}_d(x, x_1, x_2) = \ln \frac{s}{2}. \quad (5.9)$$
We have
\[ I_{u_1 u_2 g}^{(d)} = I_{u_1 u_2 g}^{(d)} + C_0 I_{u_1 u_2}^{(d)} + C_2^{(d)} I_{u_1 u_2}^{(d)}, \tag{5.10} \]
where we defined
\[ I_{u_1 u_2 g}^{(d)} \equiv \int d^d x \, u_1 \, u_2 \, g_d, \tag{5.11} \]
and
\[ I_{u_1 u_2}^{(d)} \equiv \int d^d x \, u_1 \, u_2. \tag{5.12} \]

From Eq. (5.10), we see that we can reduce the computation of \( I_{u_1 u_2 g}^{(d)} \) to that of the three integrals: \( I_{u_1 u_2 g}^{(d)} \), \( I_{u_1 u_2}^{(d)} \), and \( I_{u_1 u_2}^{(d)} \). The last integral is trivially given by the standard \( d \)-dimensional Riesz integral. After division by \( \Omega_d \), where \( \Omega_d = 2\pi^{d/2}/\Gamma(d/2) \) denotes the surface of the unit sphere in \( d \)-dimensional Euclidean space, one finds
\[ \frac{1}{\Omega_d} I_{u_1 u_2}^{(d)} = \frac{d - 2}{2d - 4} \Gamma(4 - d) \left[ 1 + \frac{\epsilon}{2} \right]^{1 - \epsilon}. \tag{5.13} \]

The intermediate integral in Eq. (5.10), namely \( I_{u_1 u_2 g}^{(d)} \), is much simpler than \( I_{u_1 u_2 g}^{(d)} \) because it is a massless two-loop, two-point (scalar) Green function. It is depicted in Fig. 10. Such Green’s functions have been computed in the Feynman-integral literature. More precisely, the Fourier transform of \( I_{u_1 u_2 g}^{(d)} \) (modulo some different normalization factors, including an overall sign) has been computed by Chetyrkin, Katuiev, and Tkachov using Gegenbauer-polynomial, \( x \)-space techniques (see also [40]). It is trivial to compute the inverse Fourier transform of the result of Refs. [40] [41] (given in Appendix A), so as to compute the exact analytical expression of \( I_{u_1 u_2 g}^{(d)} \), namely
\[ \frac{1}{\Omega_d} I_{u_1 u_2 g}^{(d)} = N_{u_1 u_2 g}^{(d)} \left[ \Gamma(1 - 3\epsilon) \right]. \tag{5.14} \]

where the numerical factor (after the convenient factoring of \( \Omega_d \), and some simplification) is found to be
\[ N_{u_1 u_2 g}^{(d)} = \frac{d - 2}{4(d - 4)} \left[ \frac{2}{d - 3} \right. \]
\[ + 2\pi \cot \frac{d\pi}{2} \Gamma(\frac{d}{2} - 5) \left/ \Gamma(\frac{d}{2} - 2) \Gamma(d - 2) \right]. \tag{5.15} \]

The \( \epsilon \)-expansion of the latter numerical factor is
\[ N_{u_1 u_2 g}^{(d)} = \frac{1}{2\epsilon} + 2 + \frac{1}{4}(18 + \pi^2)\epsilon + O(\epsilon^2). \tag{5.16} \]

Having the analytical expressions of \( I_{u_1 u_2 g}^{(d)} \) and \( I_{u_1 u_2}^{(d)} \), the formula (5.10) reduces the computation of \( I_{u_1 u_2 g}^{(d)} \) to that of \( I_{u_1 u_2 g}^{(d)} \). Though \( \hat{g}_d \) has a finite limit when \( d = 3 + \epsilon \to 3 \), and the coefficient of \( I_{u_1 u_2 g}^{(d)} \) is finite as \( \epsilon \to 0 \) [so that it is enough to control \( I_{u_1 u_2 g}^{(d)} \) to \( O(\epsilon^1) \) to get \( I_{u_1 u_2 g}^{(d)} \) to \( O(\epsilon^2) \)], there are subtleties linked to the non uniformity of \( \lim_{\epsilon \to 0} \hat{g}_d \). Indeed, one must treat separately the contributions to the spatial integral \( I_{u_1 u_2 g}^{(d)} \) coming from some (large but) finite ball, say \( |x| < R \), and the contribution from spatial infinity, i.e. for \( |x| > R \). (Henceforth, we take the origin of space at the midpoint between \( x_1 \) and \( x_2 \), because this significantly simplifies the asymptotic analysis at spatial infinity.) More precisely, let us write [where the factor \( (1 - \epsilon)^2/\Omega_d \) is added for convenience]
\[ (1 - \epsilon)^2 \frac{I_{u_1 u_2 g}^{(d)}}{\Omega_d} = -(1 - \epsilon)^2 \frac{I_{u_1 u_2}^{(d)}}{\Omega_d} + (1 - \epsilon)^2 \frac{I_{u_1 u_2}^{(d)}}{\Omega_d}, \tag{5.17} \]

where
\[ (1 - \epsilon)^2 \frac{I_{u_1 u_2}^{(d)}}{\Omega_d} < \frac{1}{\Omega_d} \int_{|x| < R} d^d x \, u_1 \, u_2 \left( (1 - \epsilon) \hat{g}_d \right)^2 \tag{5.18} \]

and
\[ (1 - \epsilon)^2 \frac{I_{u_1 u_2}^{(d)}}{\Omega_d} > \frac{1}{\Omega_d} \int_{|x| > R} d^d x \, u_1 \, u_2 \left( (1 - \epsilon) \hat{g}_d \right)^2. \tag{5.19} \]

The first (\( < \)) integral has a limit as \( \epsilon \to 0 \) which is simply given by
\[ \lim_{\epsilon \to 0} (1 - \epsilon)^2 \frac{I_{u_1 u_2}^{(d)}}{\Omega_d} < \frac{1}{4\pi} \int_{|x| < R} d^3 x \, r_1^{-1} r_2^{-1} \left( \ln \frac{s}{2} \right)^2. \tag{5.20} \]

To compute the \( \epsilon \to 0 \) limit of the second (\( > \)) integral, we need an approximation to \( (1 - \epsilon) \hat{g}_d \) that is valid near spatial infinity, and in \( d \) (rather than 3) dimensions. For orientation, we recall that in \( d = 3 \), the explicit knowledge of \( \lim_{\epsilon \to 0} \hat{g}_d \equiv \bar{g}_3 = \ln \frac{s}{2} \) allows one to compute (when \( r \equiv |x| \to \infty \))
\[ \bar{g}_3 = \ln \left( r + \frac{r_2}{2} \right) + O \left( \frac{1}{r} \right) = \ln r + \frac{r_2}{2r} + O \left( \frac{1}{r} \right). \tag{5.21} \]
The $d$-dimensional analog of this asymptotic expansion is obtained by combining the term-by-term inverse Laplacian of the asymptotic expansion of the source of $g_d$, namely

$$\Delta g_d = r_1^{2-d} r_2^{2-d} = r^{2-d} \left( 1 + O \left( \frac{1}{r^2} \right) \right), \quad (5.22)$$

with the general multipolar-expansion formula for the $(d$-dimensional) Poisson integral of an extended (but fast-decreasing at spatial infinity) source $s(x)$:

$$[\Delta^{-1}s](x) = -\frac{k}{4\pi} \int d^d y \frac{s(y)}{|x-y|^{d+2}} \left( 1 + O \left( \frac{1}{r^2} \right) \right). \quad (5.23)$$

Actually, as the relevant source, $r_1^{2-d} r_2^{2-d}$, is not fast-decreasing when $d \approx 3$, one needs to adequately combine the two informations. This leads to

$$\Delta^{-1} (r_1^{2-d} r_2^{2-d}) = \frac{r^{2-d}}{(6-2d)(4-d)} + \frac{r_1^{4-d}}{2(4-d)} r^{2-d} + \ldots, \quad (5.24)$$

which is equivalent to

$$(1-\varepsilon)g_d = \frac{1 - r^{-2\varepsilon}}{2\varepsilon} + \frac{r_1^{1-\varepsilon}}{2} - \frac{r^{1-\varepsilon}}{2} + \ldots. \quad (5.25)$$

Inserting the latter asymptotic expansion (together with the $(2-d)$th power of $r_1 r_2 = r^2(1 + O(1/r^2))$, and $d^d x = \Omega_d r^{d-1} dr$) within the definition of $\frac{1}{\Omega_d} I_{\varepsilon,12}^{(d)}$ allows one to estimate the latter integral by means of a computable radial integral which yields

$$\frac{(1-\varepsilon)^2}{\Omega_d} I_{\varepsilon,12}^{(d)} = \frac{r_1^{1-\varepsilon}}{8\varepsilon^2} - f \left( R + \frac{r_1 r_2}{2} \right) + O \left( \frac{1}{R} \right) + O(\varepsilon), \quad (5.26)$$

where we introduced the function $f(r)$

$$f(r) \equiv r \ln^2 r - 2 \ln r + 2. \quad (5.27)$$

The appearance of the term $-f(R + \frac{r_1 r_2}{2})$ is exactly what is needed to define the Hadamard-regularization of the usual 3-dimensional integral $(5.20)$. Indeed, one checks that the difference

$$\frac{1}{4\pi} \int_{|x|>R} d^3 x r_1^{-1} r_2^{-1} \left( \ln \frac{s}{2} \right)^2 - f \left( R + \frac{r_1 r_2}{2} \right) \quad (5.28)$$

has a finite limit as $R \to \infty$.

The next step is to recognize that the limit as $R \to \infty$ of $(5.28)$ can be alternatively defined by an analytic continuation as $c \sim 0$ of the integral (over the full 3-dimensional space) of

$$\frac{1}{4\pi} \int d^3 x r_1^{-1} r_2^{-1} \left( \frac{s}{2} \right)^c \left( \ln \frac{s}{2} \right)^2. \quad (5.29)$$

A subtle point here is that one obtains such a simple result [with the one-scale counterterm $f(R + \frac{r_1 r_2}{2})$] only when the exponents of $r_1$ and $r_2$ are both equal to $-1$. (Indeed, this guarantees that asymptotically $\frac{d^3 x}{r_1 r_2} = dr dS$, with $S \equiv r + \frac{r_1 r_2}{2}$.)

Let us then consider the following version of the generalized Riesz formula (with a normalization which is convenient for our present purpose)

$$\tilde{I}[a, b, c] \equiv \frac{1}{4\pi} \int d^3 x \frac{r_1}{r_2} \left( \frac{s}{2} \right)^c = \tilde{R}[a, b, c] r_1^{3+a+b} c. \quad (5.30)$$

The restriction of the generalized Riesz formula to the special case $a = b = -1$ (keeping $c$ away from zero) then yields the following very simple result

$$\tilde{I}[-1, -1, c] = -\frac{r_1 c}{1 + c}. \quad (5.31)$$

The latter result can be easily derived from scratch by using elliptic coordinates. Indeed, in elliptic coordinates $(\xi = \frac{r_1 r_2}{2}, \eta = \frac{r_1 - r_2}{2})$ one has $d^3 x / (r_1 r_2) = \frac{1}{2\pi^2} d\xi d\eta d\phi$. One then deduces that

$$\left[ \frac{\partial^2 \tilde{I}[-1, -1, c]}{\partial c^2} \right]_{c=0} = -f(r_1) \quad (5.32)$$

or, equivalently, in view of the previous reasonings, that

$$\lim_{R \to \infty} \left[ \frac{1}{4\pi} \int_{|x|<R} d^3 x r_1^{-1} r_2^{-1} \left( \ln \frac{s}{2} \right)^2 - f \left( R + \frac{r_1 r_2}{2} \right) \right] = -f(r_1) \quad (5.33)$$

9 This way of combining two expansions to get the proper behavior of $d$-dimensional inverse Laplacians near spatial infinity was devised by Gerhard Schäfer and one of us (PJ) and it was never used so far in a published work. It is an IR analogue of the $d$-dimensional UV local analysis introduced in Ref. [33] and completed (by the use of an explicit expression for the homogeneous contributions) in Appendix C4 of Ref. [10].

10 The simplicity of this result allows us to expand in powers of $c$ (i.e. to compute and integral involving integer powers of $\ln s$ by elementary means). The expansion in more general cases where $(a, b)$ deviate from $(-1, -1)$ (or other integer pairs) by $O(c)$ can also be analytically performed, though via more sophisticated techniques [42, 43].
Actually, the latter result can also be more directly derived simply by evaluating the $r < R$-truncated general­ized Riesz integral in elliptic coordinates, which yields [for large $R$, modulo $O(1/R)]$

$$
\frac{1}{4\pi} \int_{|x|<R} \frac{d^3x}{r_1 r_2} r_1^{-1} r_2^{-1} \left( \frac{s}{2} \right)^c = \frac{1}{1+c} \left[ \left( R + \frac{r_{12}}{2} \right)^{1+c} - r_1^{1+c} \right].
$$

(5.34)

Differentiating this result twice with respect to $c$ then yields (5.33).

Finally, putting together our results we can analytically compute the first three terms of the $\varepsilon$ expansion of the $x$-space integral $I_{u_1 u_2 g^2}^{(d)}$, namely

$$
\frac{1}{\Omega_d} I_{u_1 u_2 g^2}^{(d)}(x_1 - x_2) = N_{u_1 u_2 g^2}^{(d)} r_1^{-1-5\varepsilon},
$$

(5.35)

where the numerical factor (after the convenient factoring of $\Omega_d$) is found to be

$$
N_{u_1 u_2 g^2}^{(d)} = -\frac{1}{4} \left[ \frac{1}{\varepsilon^2} + \frac{7}{\varepsilon} + 30 + \pi^2 + O(\varepsilon) \right].
$$

(5.36)

The Fourier transform (with respect to $x_1 - x_2$) of this $x$-space integral, and the addition of the various needed conventional, normalization coefficients then yields the first three terms of the $\varepsilon$ expansion of the master integral $\mathcal{M}_{3,6}$, namely

$$
\mathcal{M}_{3,6}(p) = \widetilde{\mathcal{M}}_{3,6} |p|^{4\varepsilon-4},
$$

(5.37)

where (with $\gamma$ denoting Euler’s constant)

$$
\widetilde{\mathcal{M}}_{3,6} = (4\pi)^{-4-2c-2\varepsilon} e^{2\gamma} \varepsilon \left[ \frac{1}{\varepsilon^2} - \frac{1}{\varepsilon} + \frac{\pi^2}{12} - 8 + O(\varepsilon) \right].
$$

(5.38)

Our reasoning has analytically proven the latter expansion (which agrees with the result of [22]), and has, actually, reduced it to the evaluation of more elementary integrals: notably the two-loop integral $I_{u_1 u_2 g^2}^{(d)}$, and the integrals involving $\ln^2(s/2)$ discussed above, which were, actually, reduced to trivial integrals when using elliptic coordinates (and these trivial integrals did not involve any irrational coefficients).

Separately from the technical issue of analytically evaluating such integrals, let us note again that the evaluation of the contentious contributions to the four-loop effective action discussed in the previous sections involved only IR convergent integrals, while the master integral $\mathcal{M}_{3,6}$ is IR divergent (as shows up in its singular behavior as $\varepsilon \to 0$). This indicates that choosing $\mathcal{M}_{3,6}$ as one of the basis of elementary master integrals is probably not an optimal choice.

VI. CONCLUSIONS

We have shown that remarkable cancellations take place within the four-loop, 4PN, $O(G^5)$ static contribution to the original, higher-time-derivative, harmonic-coordinates effective action of a gravitationally interacting binary point-mass system. Namely, the subset of diagrams $\propto G^5 m_1^3 m_2^3 / (\delta r_{12}^2)$ (denoted $L_{33}$, $L_{49}$, $L_{50}$ in Ref. [22]) that individually involve transcendental coefficients $\in \mathbb{Q}[\pi^2] = \mathbb{Q}[\zeta(2)]$ cancel against each other to leave a final, rational coefficient $+ 2G^4$. On the one hand, this finding corrects a recent claim of Ref. [22], which found a final coefficient for the same terms equal to $\frac{1212}{9} - \frac{22}{3} \pi^2$. On the other hand, it confirms a previous lower-order finding of [34], namely the fact that the corresponding highest-power-of-$G$, static terms at the previous PN level [three-loop, 3PN, $O(G^4)$ level] did not involve any $\pi^2$ dependence, by contrast with the two-loop, 3PN, $O(G^3 \pi^2)$ terms. We leave to future work a deeper understanding of the rational-coefficient nature of such, highest-G-order, static terms at each PN order. As pointed out by Foffa et al. [22, 34], the same terms (at 3PN and 4PN) happen to be finite at $d = 3$ (in dimensional regularization). At 4PN, this finiteness comes after the cancellation of poles $\propto 1/(d-3)$ present in individual diagrams. The latter cancellations can be seen rather easily, at 4PN, from the explicit $x$-space expressions that we have given above for all the static 4PN diagrams (and not only $L_{33}$, $L_{49}$, $L_{50}$).

The cancellations discussed above are specific to the harmonic-gauge computation of the effective action. E.g., the situation is different in ADM gauge, where there are static, three-loop, 3PN, $O(G^4)$ terms involving $\pi^2$, as well as static, four-loop, 4PN, $O(G^5)$ terms involving $\pi^2$. It remains, however, true that the effective action for the gravitational interaction of point masses exhibit a remarkably small level of transcendentality. At one and two loops (at 1PN and 2PN), the action involves only rational coefficients. The 3PN, three-loop level introduces $\mathbb{Q}[\zeta(2)]$ coefficients, and this transcendentality level does not increase when going to the 3PN, four-loop level. Very-high-PN-order, analytical gravitational self-force studies of the EOB Hamiltonian [44–46] have shown (for a subset of the diagrams) that the transcendentality level increases only quite slowly as the loop number (equal to the PN level) increases: the $\mathbb{Q}[\zeta(4)] = \mathbb{Q}[\pi^4]$ level is reached at six loops, and $\zeta(3)$ first appears at the seven-loop order. [Here, we are (roughly) subtracting the effects linked to non-local-in-time interactions which introduce Euler’s constant $\gamma$ and logarithms.] We leave to future work a better understanding of such facts.

Separately from the interest of finding special structures hidden in the gravitational effective action, our work provides a confirmation of the correctness of the

11 In the sense of being independent both on velocities and their time derivatives.
4PN-level $O(m_1^2m_2^2)$ sector of the harmonic-coordinates action of [17]. This confirmation is independent of that following from its previously checked agreement with the corresponding sector of the 4PN, ADM action of [9, 10]. [In terms of the $\mu$-reduced Hamiltonian, this corresponds to $O(\nu^3)$ terms that had been first derived in Ref. [13].] Having such independent confirmations is always useful. It would be useful that a full, independent 4PN, EFT-based computation of the 4PN effective action be performed. However, in view of the complications (and sign dangers) brought by working with purely imaginary propagators, and corresponding $i$-decorated vertices, we would advocate (as explained at the end of Sec. II above) to work with real propagators $\mathcal{G} = -\mathcal{L}^{-1}$, and corresponding $i$-free vertices (when viewed in $\mathbb{R}$-space).

Let us finally comment on the technicalities of the explicit, 4PN computation. We have shown in Sec. V above that the four-loop master integral $\mathcal{M}_{3,6}$ selected as basis element in [22], and that could only be numerically computed in the latter reference, could be analytically computed by means of what has been the standard tool in ADM computations since the 3PN level, namely the generalized Riesz formula [27]. It is remarkable that a tool set up for the three-loop level can analytically deal with a four-loop integral that resisted the state-of-the-art technologies in multi-loop computations. We think that this is due to two main facts (besides the special structure of the gravitational vertices): (i) our use of $\mathbb{R}$-space integration [7] and (ii) the fact that the repeated differentiation of the generalized Riesz formula with respect to the power of $s \equiv r_1 + r_2 + r_12$ allows one to compute integrals that can show up at an arbitrary high loop order. Indeed, the $n$th derivative with respect to the power of $s$ generates $(3\text{-dimensional})$ integrals of the type, say

$$I_{n_1,n_2,n} \sim \int d^3x \frac{r_1^{-n_1}r_2^{-n_2}(\ln s)^n}{r_1^{-1}r_2^{-1}(\Delta^{-1}r_1^{-1}r_2^{-1})^n}. \quad (6.1)$$

When $n_1 = n_2 = 1$ and $n = 2$ this corresponds to the four-loop $\mathcal{M}_{3,6}$ diagram. When taking higher values of $n$, $I_{n_1,n_2,n}$ describes higher-loop master integrals.

**ACKNOWLEDGMENTS**

T.D. thank Pierre Vanhove for informative discussions, and useful references, on Feynman integrals. We thank Stefano Foffa for clarifying the precise meaning of the notation for the kinetic terms in the bulk action for $\sigma_{ij}$ and $\phi$, and notably $(\nabla \sigma)^2$. The work of P.J. was supported in part by the Polish NCN Grant No. UMO-2014/14/M/ST9/00707.

**Appendix A: Some useful formulas**

1. \textit{d-dimensional results}

The area of the $(d - 1)$-dimensional unit sphere in $\mathbb{R}^d$ reads

$$\Omega_d = \frac{2\pi^{d/2}}{\Gamma(d/2)}. \quad (A1)$$

It is convenient to introduce the constant

$$\hat{k} \equiv \frac{\Gamma(d - 1)}{\pi^{d/2}}, \quad (A2)$$

such that

$$\hat{k}\Omega_d = \frac{4\pi}{d - 2}. \quad (A3)$$

Then the $d$-dimensional Newtonian potential $u_a \equiv r_a^{2-d}$ fulfills the equation

$$\Delta (\hat{k} r_a^{2-d}) = -4\pi\delta_a. \quad (A4)$$

The (ordinary) Riesz formula in $d$ dimensions reads

$$\int d^d x r_a^{\delta_b c}(d) r_1 r_2 = \pi^2 r_a^{(6)}(d) r_{12}^{a+b+d}, \quad (A5a)$$

with

$$r_a^{(6)}(d) \equiv \frac{\Gamma\left(\frac{a+b+d}{2}\right)\Gamma\left(\frac{b+c+d}{2}\right)\Gamma\left(-\frac{a+b+d}{2}\right)}{\Gamma(\delta_a)\Gamma\left(-\frac{1}{2}\right)\Gamma\left(\frac{a+b+c+d}{2}\right)}. \quad (A5b)$$

A three-dimensional generalization of the Riesz formula [A5] for integrals of the form $r_1^{\delta_b c}(r_1 + r_2 + r_12)^c$ was derived in Ref. [27]. It reads

$$\int d^3 x r_1^{\delta_b c}(r_1 + r_2 + r_12)^c = 2\pi R(a, b, c) r_{12}^{a+b+c+3}, \quad (A6a)$$

where

$$R(a, b, c) \equiv \frac{\Gamma(a + 2)\Gamma(b + 2)\Gamma(-a - b - c - 4)}{\Gamma(-c)} \times \left[ I_{1/2}(a + 2, -a - c - 2) + I_{1/2}(b + 2, -b - c - 2) - I_{1/2}(a + 4, -a - b - c - 4) - I_{1/2}(b + 4, -a - b - c - 4) - I_{1/2}(a + b + 4, -a - b - c - 4) - 1 \right]. \quad (A6b)$$

---

12 We note in this respect that the first five four-loop master integrals in Fig. 3 of [22] are trivial to compute in $\mathbb{R}$-space. Indeed, repeated lines between two points just mean a power of $r_12$, $r_2$ or $r_1$, without any needed integration. The only needed integrations in $\mathbb{R}$-space go with the number of intermediate vertices; for instance, $\mathcal{M}_{1,1}$, $\mathcal{M}_{1,2}$, $\mathcal{M}_{1,3}$ and $\mathcal{M}_{1,4}$ only involve one intermediate-point integration, so that they are immediately derived from the normal Riesz formula, while $\mathcal{M}_{3,6}$ involves three intermediate-points integrations.
The function $I_{1/2}$ is defined as follows:

$$I_{1/2}(x, y) \equiv \frac{B_{1/2}(x, y)}{B(x, y)},$$  \hspace{1cm} (A7)

where $B$ is the Euler beta function and $B_{1/2}$ is the incomplete beta function which can be expressed in terms of the Gauss hypergeometric function $2F_1$:

$$B_{1/2}(x, y) = \frac{1}{2^x} 2F_1\left(1 - y, x; x + 1; \frac{1}{2}\right).$$  \hspace{1cm} (A8)

The $d$-dimensional Fourier transform of a power reads:

$$\int \frac{dp}{(2\pi)^d} \frac{\Gamma(a)}{(p^2)^a} = \frac{1}{\pi^{d/2} 2^a} \Gamma\left(\frac{d}{2} - a\right).$$  \hspace{1cm} (A9)

The result of [10] (and [41]) for the $p$-space version of the two-loop diagram of Fig. 17 reads:

$$\int \frac{dk \, dk'}{k^2 k'^2 (k - p)^2 (k - p')^2 (k - l)^2} = \frac{(p^2)^{d-5}}{(4\pi)^d} \Gamma^{(8)}(d),$$  \hspace{1cm} (A10)

where

$$\Gamma^{(8)}(d) \equiv \frac{\Gamma\left(\frac{d}{2} - 2\right) \Gamma\left(2 - \frac{d}{2}\right) \Gamma\left(\frac{d}{2} - 1\right)}{\Gamma(d - 2)} \times \left(\frac{\Gamma(3 - \frac{d}{2}) \Gamma\left(\frac{d}{2} - 1\right)}{\Gamma(d - 3)} - \frac{\Gamma(d - 3) \Gamma(5 - d)}{\Gamma(3 - \frac{d}{2}) \Gamma(\frac{d}{2} - 5)}\right).$$  \hspace{1cm} (A11)

2. Distributions in $d = 3$ dimensions

In Sec. IV we have to compute different distributional derivatives. We collect here formulae which can be used for this goal. Let us start from identities involving Dirac delta distribution and its derivatives:

$$f \delta_a = f_{\text{reg}}(x_a) \delta_a,$$  \hspace{1cm} (A12a)

$$f \nabla \delta_a = - (\nabla f)_{\text{reg}}(x_a) \delta_a + f_{\text{reg}}(x_a) \nabla \delta_a,$$  \hspace{1cm} (A12b)

$$f \Delta \delta_a = (\Delta f)_{\text{reg}}(x_a) \delta_a - 2 (\nabla f)_{\text{reg}}(x_a) \nabla \delta_a + f_{\text{reg}}(x_a) \Delta \delta_a.$$  \hspace{1cm} (A12c)

Because usually the function $f$ for which the above identities are used is singular at $x = x_a$, the symbol $f_{\text{reg}}(x_a)$ means the regularized “partie finie” value of the function $f$ at $x = x_a$ (for its definition and properties see, e.g., Appendix A4 of Ref. [10]).

We have also employed distributional derivatives to calculate first and second partial derivatives of homogeneous functions $1/r_a$, $1/r_a^2$, and $1/r_a^3$ (for derivation and properties see, e.g., Appendix A5 of Ref. [10]). The first partial derivatives read

$$\partial_i \frac{1}{r_a} = \frac{n_i}{r_a^3},$$  \hspace{1cm} (A13a)

$$\partial_i \frac{1}{r_a^2} = \frac{2n_i}{r_a^4},$$  \hspace{1cm} (A13b)

$$\partial_i \frac{1}{r_a^3} = - \frac{3n_i}{r_a^5} - \frac{4\pi}{3} \partial_i \delta_a.$$  \hspace{1cm} (A13c)

The second partial derivatives are

$$\partial_i \partial_j \frac{1}{r_a} = \frac{3n_i n_j - \delta_{ij}}{r_a^3} - \frac{4\pi}{3} \delta_{ij} \delta_a,$$  \hspace{1cm} (A14a)

$$\partial_i \partial_j \frac{1}{r_a^2} = \frac{2(4n_i n_j - \delta_{ij})}{r_a^4},$$  \hspace{1cm} (A14b)

$$\partial_i \partial_j \frac{1}{r_a^3} = \frac{3(5n_i n_j - \delta_{ij})}{r_a^5} - \frac{2\pi}{15} (16 \partial_i \partial_j \delta_a + 3 \delta_{ij} \Delta \delta_a).$$  \hspace{1cm} (A14c)

Tracing the above formulas yields

$$\Delta \frac{1}{r_a} = -4\pi \delta_a,$$  \hspace{1cm} (A15a)

$$\Delta \frac{1}{r_a^2} = \frac{2}{r_a^4},$$  \hspace{1cm} (A15b)

$$\Delta \frac{1}{r_a^3} = \frac{6}{r_a^6} - \frac{10\pi}{3} \Delta \delta_a.$$  \hspace{1cm} (A15c)

As an application of the above formulas let us note a useful expression which shows how to compute the Laplacian of the product of a (singular at $x = x_a$) function $f$ and $1/r_a^3$:

$$\Delta \left( f \frac{1}{r_a^3} \right) = \Delta \left( f \frac{1}{r_a^3} \right)_{\text{ord}} + 2\pi \frac{3}{3} (\Delta f)_{\text{reg}}(x_a) \delta_a + 4\pi (\nabla f)_{\text{reg}}(x_a) \cdot \nabla \delta_a - \frac{10\pi}{3} f_{\text{reg}}(x_a) \Delta \delta_a,$$  \hspace{1cm} (A16)

where $\Delta (f/r_a^3)_{\text{ord}}$ means the Laplacian computed using standard (i.e. non-distributional) rules of differentiations.
