(Dated: May 25, 2009)

The influence of electromagnetic radiation on the electron transport in a quantum channel with a single short-range scatterer is investigated using a generalized Landauer-Büttiker approach. We have shown that asymmetrical position of the scatterer leads to appearance of the direct photocurrent in the system. The dependence of the photocurrent on the electron chemical potential, the position of the scatterer, and the frequency of the radiation is studied. We have shown that the photocurrent and the photoconductance oscillate as functions of the electron chemical potential. The nature of oscillations is discussed.

1. INTRODUCTION

The study of electron transport in nanostructures under the external electromagnetic radiation has been attracting considerable attention during the last few years. The interest to the problem is stipulated by recent attempts to create a sensitive nanometer-size photodetector. Photon-induced electron transport in a number of interesting systems such as quantum point contacts,1-5 field-effect transistors, quantum dots,6 and carbon nanotubes9,10 was studied in various experiments. Quantum ratchet effects induced by terahertz radiation were observed in GaN-based two-dimensional structures.11 Impurity photocurrent spectra of bulk GaAs and GaAs quantum wells doped with shallow donors were studied.14 It was shown experimentally15 that the photoconductance of the quantum point contact oscillates with the gate voltage. In the case of asymmetrical illumination, the direct photocurrent arises in the quantum point contact.16 The photocurrent was attributed to the radiation-induced thermopower.

A lot of theoretical models have been used to study the microwave induced electron transport in bulk materials and low-dimensional systems. Photon-assisted tunneling in a resonant double barrier system was investigated within the scattering approach. Various quantum dot photodetectors were studied theoretically. The photoconductivity of quantum wires and microconstrictions with an adiabatic geometry was investigated using different calculation methods.17 It was found that absorption of high-frequency electromagnetic field polarized in transversal direction results in oscillations of the photoconductance as a function of the gate voltage. Circular photogalvanic effect in benzen22 and helical23 one-dimensional quantum wires was studied. Radiation-induced current in quantum wires with side-coupled nanorings was calculated.24 One-dimensional quantum pump based on two harmonically oscillating δ-potentials was investigated in Refs. 25-28. Various interesting photon and phonon depended effects were predicted in carbon nanotube devices.27-29 A number of papers are devoted to the theoretical study of the spin-depended photogalvanic effects.30-32

A consistent quantitative theory of photogalvanic effect in bulk samples was given by Belinicher and Sturman.33 The necessary condition for appearance of the photocurrent is the absence of the inversion symmetry in the system. In the macroscopic samples, the absence may be stipulated by the asymmetry of the lattice or by oriented asymmetric scatterers.

Ballistic transport regime in quasi one-dimensional nanostructures allows another mechanism. The symmetry may be broken by an asymmetrically located single scatterer, for instance, a potential barrier or an impurity. In the present paper, we consider one of the simplest nanoscale system that allows generation of the direct current induced by electromagnetic radiation.

2. HAMILTONIAN

The purpose of the present paper is the theoretical investigation of the photocurrent in a quantum channel containing a single point defect. It should be mentioned that the elastic scattering in similar systems has been widely discussed in literature.43,44,45,46,47,48,49 We consider the channel that is formed in the two-dimensional electron gas by parabolic confining potential. The schematic view of the device is shown in Fig. 1.

The electron motion in the channel is described by the Hamiltonian

$$\hat{H}_0 = \frac{p_x^2}{2m} + \frac{p_y^2}{2m} + \frac{m \omega_0^2 y^2}{2}. \quad (1)$$

where $m$ is effective electron mass, $\omega_0$ is the frequency of parabolic confining potential, $p_x$ and $p_y$ are projections of the momentum (the $x$ direction corresponds to the axis of the channel). Eigenvalues $E_{n,p}$ and eigenfunctions $\phi_{n,p}$...
of the Hamiltonian $\hat{H}_0$ are well-known

$$E_{n,p} = \frac{p^2}{2m} + E_n, \quad \phi_{n,p}(x,y) = \Phi_n(y)e^{ipx/\hbar}, \quad (2)$$

where $E_n = \hbar\omega n + 1/2$, and $\Phi_n(y)$ are oscillator functions. We note that the effective channel width is determined by the number of occupied subbands and by the characteristic oscillator length $a = \sqrt{\hbar/m\omega_0}$.

The short-range defect is modelled by the zero-range potential $49,50,51,52,53$ and therefore the Hamiltonian $\hat{H}_d$ of the channel with the defect is a point perturbation of the Hamiltonian $\hat{H}_0$. Actually, the point perturbation is determined by boundary conditions for the wave function at the defect point. The similar method has been used earlier $53,54,55$ for modelling of point contacts.

Boundary values for the wave function are determined with the help of the zero-range potential theory $50,51,52,53$. The theory shows that the electron wave function $\psi(x)$ has the logarithmic singularity in a vicinity of the defect point $r_d$. As follows form the theory of zero-range potentials the wave function $\psi(x)$ of the Hamiltonian with the point perturbation may be represented in terms of the Green’s function. That is why the wave function has the same singularity as the Green’s function in the vicinity the point of perturbation. We note that the form of the singularity is determined by the dimension of space only. It is independent on energy and form of smooth confining potential. In particular, the singularity is logarithmic in the two-dimensional case

$$\psi(r) = -u \ln |r - r_d| + v + R(r), \quad (3)$$

where $u$ and $v$ are complex coefficients, and $R(r)$ is the remainder term that tends to zero in the limit $r \to r_d$. Coefficients $u$ and $v$ play the role of boundary values for the wave function $\psi$. They are independent of $r$. The boundary conditions at the point of contact are some linear relations between $u$ and $v$:

$$v = P_0u. \quad (4)$$

Here the coefficient $P_0$ determines the strength of the zero-range potential at the point $r_d$. It should be noted that the zero-range potential is attractive and the limit $|P_0| \to \infty$ corresponds to the absence of the point perturbation.

We suppose that the channel is exposed by an external electromagnetic wave propagating in the $z$ direction and polarized in the $y$ direction. We assume that electron-photon interaction takes place in the region of the channel only that may be realized by an antenna $54$ or by an opaque diaphragm (Fig. 1). In the view of these assumptions the influence of the electromagnetic field on the electron is described by the operator

$$\hat{V}(t) = \frac{e\varepsilon_0^2}{\mu_0}[(\theta(x) - \theta(x - L)) \cos(\omega t)] = \hat{V}_0(e^{i\omega t} + e^{-i\omega t}), \quad (5)$$

where $\varepsilon$ is the amplitude of the electric field, $\omega$ is the frequency of radiation, and $\theta(x)$ is the Heaviside step function, i.e., $\theta(x) = 1$ for $x > 0$ and $\theta(x) = 0$ otherwise.

To obtain the electric current in the channel we use the generalization $18,22,24,56,57$ of the Landauer–Büttiker formula $58,59$ that takes into account the radiation

$$I = \frac{e}{\pi\hbar} \sum_{n,n'} \int_0^\infty [T_{n'n}^R(E + \hbar\omega,E)f_L(E)]^2 \left[ T_{n'n}^R(E + \hbar\omega,E)f_R(E)\right] dE. \quad (6)$$

Here $T_{n'n}^R(E + \hbar\omega,E)$ is the transmission probability between the state with the energy $E$ and the quantum number $n$ in the left reservoir and the state with the energy $E + \hbar\omega$ and the quantum number $n'$ in the right reservoir, $f_L$ and $f_R$ are Fermi distribution functions for the left and the right reservoirs respectively, and $l$ is the number of absorbed photons (negative $l$ corresponds to emission of photons). Function $f_j$ (here $j$ means left (L) or right (R) electron reservoir) has the form

$$f_j(E) = \frac{1}{\exp[(E - \mu_j)/T] + 1}, \quad (7)$$

where $\mu_j$ is the chemical potential in the $j$-th reservoir and $T$ is temperature. In the paper, we consider the first order of the perturbation theory and restrict ourselves to $l = -1,0,1$.

Transmission coefficients $T_{n'n}^{ij}(E + \hbar\omega,E)$ can be represented via transmission amplitudes $t_{n'n}^{ij}(E + \hbar\omega,E)$ (here indexes $i$ and $j$ mean left (L) or right (R) reservoirs)

$$T_{n'n}^{ij}(E + \hbar\omega,E) = \frac{k_{n'n}^l}{k_{n'}^l} \left| t_{n'n}^{ij}(E + \hbar\omega,E)\right|^2, \quad (8)$$

where wave number $k_{n'n}^l$ is given by

$$k_{n'n}^l = \sqrt{2m(E - E_n + \hbar\omega)/\hbar}. \quad (9)$$
3. Photocurrent

In the linear response approximation the current is represented in the form

$$I = I_{\text{ph}} + GU_{\text{bias}}, \quad (10)$$

where $I_{\text{ph}}$ is the zero-bias photocurrent, $G$ is conductance of the system, and $U_{\text{bias}}$ is the bias voltage. The photocurrent $I_{\text{ph}}$ is given by

$$I_{\text{ph}} = \frac{e}{\pi \hbar} \int_0^\infty f(E) \Delta T(E) dE, \quad (11)$$

where

$$\Delta T(E) = \sum_{l=\pm 1} \sum_{nn'} \left[ T_{nn'}^{RL}(E + i\hbar \omega, E) - T_{nn'}^{RL}(E + i\hbar \omega, E) \right]. \quad (12)$$

We note that the terms with $l = 0$ are cancelled in Eq. (12) due to the time-reversal symmetry of elastic scattering.

To obtain the transmission probabilities we use the concept of quasi-energy states. Since the Hamiltonian of the system varies periodically with time the electron wave function may be represented in the form

$$\Psi(r,t) = \sum_l \psi_l(r) \exp[-i(F + i\hbar \omega)t/\hbar], \quad (13)$$

where $F$ is the quasi-energy. From the Schrödinger equation we obtain the following relations for the functions $\psi_l(r)$

$$[\hat{H}_d - (F + i\hbar \omega)]\psi_l(r) + \hat{V}_0\psi_{l+1}(r) + \hat{V}_0\psi_{l-1}(r) = 0. \quad (14)$$

In the first order of the perturbation theory, we restrict ourselves to $l = -1, 0, 1$ and express the functions $\psi_{l\pm 1}$ in terms of the Green’s function $G_d$ of the Hamiltonian $\hat{H}_d$

$$\psi_{l\pm 1}(r) = -\int G_d(r, r'; F \pm i\hbar \omega) \hat{V}_0 \psi_0(r') dr', \quad (15)$$

where $\psi_0(r)$ is determined from the equation

$$(\hat{H}_d - F)\psi_0(r) = 0. \quad (16)$$

It should be mentioned that the Green’s function $G_d(r, r'; F)$ is the integral kernel of the operator $(\hat{H}_d - F)^{-1}$.

We note, that at real quasi-energies the perturbation theory is inapplicable in the vicinity of the eigenvalues $E_n$ of the Hamiltonian $\hat{H}_0$ since the Green’s function has the root singularities at these energies. This phenomenon is stipulated by infinite lifetime of the states with zero speed. Therefore the electrons having zero speed are influenced by electromagnetic field for an infinitely long period of time, and hence the transition probability for these electrons is not small. To avoid peculiarities in the expression for $\psi_{l\pm 1}$ we introduce the complex quasi-energy $F = E + i\Gamma$. The imaginary part $\Gamma$ of the quasi-energy is a phenomenological parameter that may be expressed in terms of effective state lifetime $\tau$ via the relation $\Gamma = \hbar / \tau$. We mention that broadening $\Gamma$ may be caused by spontaneous transitions and inelastic scattering processes.

The zero-range potentials theory shows that the eigenfunction of the Hamiltonian $\hat{H}_d$ can be represented in the form

$$\psi_0(r, E) = \phi_0(r, E) - \frac{\phi_0(r_d, E)}{Q(r_d, E) - P} G_0(r, r_d; E), \quad (16)$$

where $\phi_0$ is the eigenfunction and $G_0(r, r'; E)$ is the Green’s function of the Hamiltonian $\hat{H}_0$, $P = P_0 + \text{const}$ is a parameter that determines the strength of the point perturbation, and $Q(r_d, E)$ is the Krein’s Q-function that is the renormalized Green’s function. The renormalization is obtained by subtracting of the logarithmic singularity at $r \to r_d$ from $G_0(r_d, r, E)$. We note, that Krein’s Q-function is defined up to additive constant. This constant determines the connection between the value of parameter $P$ and the strength of point perturbation. In the present paper, we focus on effects independent of the value of the point potential, so the value of constant is not very important for our purposes. Since the form of singularity of the Green’s function is independent of energy we can get Krein’s Q-function by the following equation

$$Q(r_d, E) = \lim_{r \to r_d} [G_0(r_d, r, E) - G_0(r_d, r, E_0)]. \quad (17)$$

Here $E_0$ is some fixed value of energy that is smaller than the ground state energy. Actually, $E_0$ determines the difference between parameters $P$ from Eq. (16) and $P_0$ from Eq. (4). In the present paper, we take $E_0 = 0$ and define the strength of the point perturbation by the parameter $P$.

To obtain the transmission amplitudes we should take $\phi_0$ as an incident wave propagating in the $n$ mode

$$\phi_0(r, E) = \Phi_n(y)e^{ik_n^0x}. \quad (18)$$

The Green’s function $G_0$ is given by equation

$$G_0(r, r'; E) = \frac{im}{\hbar^2} \sum_{n=0}^{\infty} \frac{\Phi_n(y)\Phi_n^*(y')}{k_n^{0}} e^{ik_n^{0}|x-x'|}, \quad (19)$$

where $\text{Re} k_n^{0} \geq 0$ and $\text{Im} k_n^{0} \geq 0$.

The Green’s function $G_d$ of the Hamiltonian $\hat{H}_d$ is represented in terms of the Green’s function $G_0$ of the Hamiltonian $\hat{H}_0$ using the Krein resolvent formula

$$G_d(r, r'; E) = G_0(r, r'; E) - \frac{G_0(r, r_d; E)G_0(r_d, r'; E)}{Q(r_d, E) - P} \quad (20)$$

From the asymptotics of the functions $\psi_{l\pm 1}(r)$ at the right edge of the channel we obtain transmission amplitudes.
\( t_{n'n}^{RL} \) and \( t_{n'n}^{LR} \). Details of the derivation are given in the Appendix. Then we calculate transmission coefficients and the photocurrent using Eq. (11).

To write down the equation for \( t_{n'n}^{RL} \), we need some preliminary notations:

\[
A = \frac{e\alpha}{\sqrt{8\hbar \omega}}, \quad f_n = \frac{\Phi_n(y_d)}{k_n},
\]

and

\[
\alpha^+(n,l) = -\frac{m}{\hbar^2} \frac{\Phi_n(y_d)}{Q(r_d, E + l\hbar \omega - \Phi^*)}
\]

Now we can represent the amplitude in the form

\[
t_{n'n}^{RL}(E + l\hbar \omega, E) = Ae^{ik_L^j L} \left[ t^{(1)} + t^{(2)} + t^{(3)} + t^{(4)} \right], \tag{21}
\]

where

\[
t^{(1)} = \frac{1}{ak_n^L} J_1(k_n^L, -k_n^L, L) \left[ \sqrt{n + 1} \delta_{n', n+1} - \sqrt{n} \delta_{n', n-1} \right], \tag{22}
\]

\[
t^{(2)} = \frac{\alpha^-(n', \ell)}{ak_n^L} \left[ \sqrt{n + 1} J_1(k_n^L, k_n^L, L) - \sqrt{n} J_1(k_n^L, k_n^L, L) \right], \tag{23}
\]

\[
t^{(3)} = \frac{\alpha^+(n, 0)}{ak_n^L} \sum_{m=0}^{\infty} f_m \left[ \sqrt{m} J_3(k_m^L, k_m^L, L) - \sqrt{m+1} J_3(k_m^L, k_m^L, L) \right]. \tag{24}
\]

Here \( J_1, J_2 \) and \( J_3 \) are elementary integrals:

\[
J_1(k_1, k_2, L) = \frac{1}{a} \int_0^L e^{i(k_1 + k_2)x} \, dx, \quad J_2(k_1, k_2) = \frac{1}{a} \int_0^L e^{ik_1 x} \, dx, \quad J_3(k_1, k_2) = \frac{1}{a} \int_0^L e^{ik_1 x} \, dx.
\]

The transmission amplitude \( t_{n'n}^{RL}(E + l\hbar \omega, E) \) from the right to the left reservoir is obtained from Eq. (21) via replacing \( x_d \) by \( L - x_d \) in integrals \( J_2 \) and \( J_3 \).

The dependence of the photocurrent on the chemical potential \( \mu \) is represented in Fig. 2(a). The corresponding values of \( \Delta T(\mu) \) are shown in Fig. 2(b). One can see that photocurrent oscillates with increase of the chemical potential. The amplitude of oscillations depends linearly on the intensity of radiation. The contribution to the photocurrent has sharp peaks in the vicinity of the energies \( E_n \). The sign of contribution is different for even and odd values of \( n \).

To explain the behavior of the photocurrent we consider a simplified model of the system. In this model, the channel is divided into three parts and the transmission probabilities through each part are combined incoherently. That means the transmission coefficients are defined by equation

\[
T_{n'n'}^{RL} = \sum_{m'm} W_{n'm'} R_{m'm} W_{m'n}, \tag{26}
\]

where \( R_{n'm'} \) and \( W_{m'n} \) are photon assisted transition probabilities in the left and the right parts of the channel and \( T_{m'm} \) are elastic transmission coefficients without taking the radiation into account. The transition probabilities \( W_{j'n} \) are determined by the same quasi-energy approach as indicated above but Eqs. (18) and (19) are used for the wave function and the Green’s function instead of Eqs. (16) and (20):

\[
W_{j'n} = \frac{k_l^j}{k_n} \left| \frac{A_j(k_n^0, -k_n^0, L_j) e^{ik_n L_j}}{ak_n^L} \right|^2 \times (n + 1) \delta_{m,n+1} + n \delta_{m,n-1}. \tag{27}
\]

Here \( L_j = x_d \) for the left part of the channel and \( L_j = L - x_d \) for the right part.

The transmission coefficients \( T_{m'm} \) are obtained from Eq. (16) and have the form

\[
T_{n'n}(E) = \delta_{n'n} - \frac{im}{\hbar^2 k_n^L} \frac{\Phi_n(y_d) \Phi_n^*(y_d)}{Q(r_d, E - \Phi^*)}. \tag{28}
\]

Although the approach is sufficiently rough it allows to obtain a simple explanation of the phenomena. According to this approach the photocurrent is stipulated by the difference in transmission probabilities for states with different quantum number \( n \). Using the symmetric properties of transmission coefficient we can represent the difference \( \Delta T \) in the form

\[
\Delta T(E) = \sum_{l=\pm 1} \sum_{m \neq n} \Delta W_{nm}(E + l\hbar \omega, E) \times [T_m(E + l\hbar \omega) - T_n(E)], \tag{29}
\]
transmission coefficients: the following asymptotic equation for the difference of the electron transitions from the state with even \( |y \) oscillates with increase of the chemical potential. Therefore the photocurrent increases and contributes negatively in the opposite case. The number of occupied states of different parity depends on the chemical potential. Hence the electron transitions from the state with even \( n \) to the state with odd \( n \) increase the transmission probability. The number of occupied states of different parity depends on the chemical potential. Therefore the transmission probability increases with increase of the chemical potential.

Let us consider the effect of the scatterer position. The dependence of the photocurrent on the chemical potential and the scatterer position is represented in Fig. 3. One can see that the sequence of peaks and dips of the photocurrent is changed if the scatterer is shifted from the channel axis \( (y_d \neq 0) \). The photocurrent tends to zero when the defect is placed sufficiently far from the channel axis \( (|y_d| \gg a) \) because the defect does not change the transmission probability in this case.

\[
\Delta W_{nm} = W_{nm}^L - W_{nm}^R \quad \text{and} \quad T_n(E) = \sum_{n'} T_{n'n}(E).
\]

One can see that the electron transition contributes positively to the photocurrent if the transmission probability increases and contributes negatively in the opposite case.

If the scatterer is located on the axis of the channel \( (y_d = 0) \) then the states with odd \( n \) are not reflected since the wave function vanishes at the point \( r_d \). Hence the electron transitions from the state with even \( n \) to the state with odd \( n \) increase the transmission probability. The number of occupied states of different parity depends on the chemical potential. Therefore the transmission probability oscillates with increase of the chemical potential.

Let us consider the simplest case of the axial scatterer position \( (y_d = 0) \), and resonance frequency of radiation \( (\omega = \omega_0) \). If the defect is placed in the vicinity of the channel center \( (|x_d - L/2| \ll L) \), our approach gives the following asymptotic equation for the difference of transmission coefficients:

\[
\Delta T(E) \simeq (-1)^N A^2 \frac{2(2N + 1)L\Delta x}{(a^2|k_N^R|)^2} e^{-2 \text{Im} k_N^R L} E \to E_N + 0 \quad \text{as} \quad E_N + 0. \quad \text{Here} \quad \Delta x = x_d - L/2. \quad \text{One can see from Eq. (31)} \quad \text{that the contribution to the photocurrent from the vicinity of} \quad E_N \quad \text{is positive for even} \quad n \quad \text{and negative for odd} \quad n. \quad \text{The photocurrent is proportional to} \quad \Delta x \quad \text{and it vanishes in the case of symmetrical disposition of the defect. The amplitude of the peak grows with increase of the mode number} \quad N \quad \text{proportional to} \quad 2N + 1. \quad \text{Therefore the amplitude of the photocurrent oscillations increases with chemical potential. As it follows from Eq. (31), the contribution to the photocurrent is maximal from slow electrons. This result is in agreement with Fig. 2(b) based on the more precise approach. The phenomenon is caused by sufficiently long exposure time and large density of states for slow electrons.}

Let us discuss the effect of the scatterer position. The dependence of the photocurrent on the chemical potential and the scatterer position is represented in Fig. 3. One can see that the sequence of peaks and dips of the photocurrent is changed if the scatterer is shifted from the channel axis \( (y_d \neq 0) \). The photocurrent tends to zero when the defect is placed sufficiently far from the channel axis \( (|y_d| \gg a) \) because the defect does not change the transmission probability in this case.

\[
\text{FIG. 2: (a) Dependence of the photocurrent} \quad I_{\mu \phi} \quad \text{on the chemical potential} \quad \mu \quad \text{at} \quad L = 0.5\mu m, \quad a = 10nm, \quad T = 4K, \quad y_d = 0, \quad x_d = 0.6L, \quad \omega = \omega_0 = 1.7 \times 10^{13}s^{-1}, \quad \tau = 6 \times 10^{-11}s, \quad m = 0.067m_e. \quad \text{Intensity of radiation is} \quad 0.5W/cm^2. \quad \text{(b) Dependence} \quad \Delta T(\mu) \quad \text{at the same parameters.}
\]

\[
\text{FIG. 3: (Color online) Dependence of the photocurrent on the chemical potential and the position of the scatterer. All parameters besides} \quad y_d \quad \text{are the same as in Fig. 2.}
\]

The dependence of the photocurrent on the frequency of radiation and the chemical potential is represented in Fig. 3. One can see that the photocurrent decreases with deviation of the frequency from the resonance value \( \omega_0 \).

Our numerical analysis shows that more simplified ‘incoherent’ method of calculation is in qualitatively agreement with more precise method based on Eqs. (21)- (25). But asymptotics given by Eq. (31) for \( \Delta T(E) \) is not valid for very small values of \( \Gamma \). According to Eq. (31) \( \Delta T(E) \to \infty \) at \( \mu = E_N \) as \( \Gamma \to 0 \). However, more precise analysis based on Eqs. (21)-(25) shows that \( \Delta T(E) \) remains finite. The difference between the approaches is based on taking the quantum coherence into account. We mention, that all figures are plotted using Eqs. (21)-(25).

4. PHOTOCONDUCTANCE

Let us consider the effect of the radiation on the conductive properties of the device. According to Eqs. (9) and (10) the conductance \( G \) can be represented in the
where $G_{\text{dark}}$ is ‘dark’ quasiballistic conductance of the channel with the defect and $G_{\text{ph}}$ is photoconductance.

At the zero temperature the conductance $G_{\text{dark}}$ may be represented in the form

$$G_{\text{dark}}(\mu) = G_0 \sum_{n,n'} T_{n'n}(\mu),$$

(36)

where $T_{n'n}$ are transmission coefficients for elastic scattering given by Eq. (28).

Using Eqs. (19) and (28), we can represent the zero-temperature conductance $G_{\text{dark}}(\mu)$ in the form

$$G_{\text{dark}}(\mu) = G_0 \left( N(\mu) - \left| \frac{\text{Im} Q(r_d, \mu)}{Q(r_d, \mu) - P} \right|^2 \right).$$

(37)

Here $N(E) = [E/\hbar \omega - 1/2]$ is the number of occupied sub-bands ($[x]$ means integer part of $x$). It is clear, that at finite temperatures the conductance $G_{\text{dark}}(\mu, T)$ is given by the integral similar to Eq. (32). The dependence $G_{\text{dark}}(\mu)$ in the case of axial scatterer position ($y_d = 0$) is shown in Fig. 5. One can see that the steps corresponding to even values of $n$ are smoothed due to scattering on the defect while the steps with odd values of $n$ are conserved because electrons with odd values of $n$ are not scattered.

FIG. 5: Dependence of the ‘dark’ conductance $G_{\text{dark}}$ on the chemical potential $\mu$ at $y_d = 0$ and $T = 0$.

Photoconductance $G_{\text{ph}}$ is given by equation

$$G_{\text{ph}} = G_0 \int_0^\infty \left( -\frac{\partial f}{\partial E} \right) T^{\text{ph}}(E) dE,$$

(38)

where

$$T^{\text{ph}}(E) = \sum_n \left[ \bar{T}_n(E) R_n(E) - \bar{R}_n(E) T_n(E) \right].$$

(39)

Here $T_n(E)$ and $R_n(E)$ are total elastic transmission and reflection probabilities for mode $n$ while $\bar{T}_n(E)$ and $\bar{R}_n(E)$ are total photon-assisted transmission and reflection probabilities for mode $n$. Probability $T_n$ is given by
Eq. (30) and $R_n$ is defined by $R_n(E) = 1 - T_n(E)$. According to Eq. (34), $\tilde{T}_n(E)$ and $\tilde{R}_n(E)$ are given by the following equations:

$$\tilde{T}_n(E) = \frac{1}{2} \sum_{l=\pm 1} \sum_{n'} [T_{n'n}^{RL}(E + i\hbar \omega, E) + T_{n'n}^{LR}(E + i\hbar \omega, E)]$$

(40)

and

$$\tilde{R}_n(E) = \frac{1}{2} \sum_{l=\pm 1} \sum_{n'} [R_{n'n}^{LL}(E + i\hbar \omega, E) + R_{n'n}^{RR}(E + i\hbar \omega, E)].$$

(41)

The photoconductance as a function of the chemical potential oscillates as well as the photocurrent. The dependence of the photocurrent on the chemical potential contains sharp peaks and dips in the vicinity of steps of the ballistic conductance. In the case of axial defect position, the sign of the photoconductance is determined by the parity of the highest occupied subband in the channel at the zero temperature. The transmission probabilities for different electron subbands in the channel. If the defect is placed on the axis of the channel then the odd electron subbands are not reflected by the defect since corresponding wave function vanishes at the point of the scatterer. Thus the photon-induced transitions between electron subbands of different parity can either increase or decrease the transmission probability. The probability of photon-induced transition depends on the distance from the channel edge to the defect. Therefore, the direct current arises in the case of asymmetric scatterer position. We have shown that the photocurrent oscillates as a function of chemical potential. The direction of the current is determined by the number of occupied subbands of different parity. The sequence of oscillating minima and maxima is changed if the scatterer is placed aside the channel axis. The photocurrent is proportional to the intensity of radiation and grows with increase of the lifetime $\tau$. The amplitude of oscillations reaches maximum when the frequency $\omega$ of radiation coincides with the characteristic frequency $\omega_0$ of the confining potential in the channel. This feature of the system gives the possibility to vary the resonance frequency by changing the geometry of the channel.

If the scatterer is placed in the central cross-section of the channel the photocurrent is absent but the defect influences the conductance of the system. The total conductance of the system may be represented as a sum of the 'dark' quasi-ballistic conductance $G_{\text{dark}}$ and the photoconductance $G_{\text{ph}}$, that is proportional to the intensity of radiation. The dependence of the photoconductance on the chemical potential contains sharp peaks and dips in the vicinity of steps of the ballistic conductance. In the case of axial defect position, the sign of the photoconductance is determined by the parity of the highest occupied subband in the channel at the zero temperature. The nature of the photoconductance oscillations is similar to the nature of the photocurrent oscillations. However, the dependence of the photoconductance on the chemical potential is sharper and more sensitive to the temperature than the dependence of the photocurrent. The growths of temperature leads to the smoothing of photoconductance peaks and decrease of their amplitudes.

5. CONCLUSION

Photon-induced electron transport in the quantum channel with a single point defect is investigated using modified Landauer–Buttiker formalism. The dependence of the photocurrent on the electron chemical potential is studied both analytically and numerically. We have shown that the photocurrent is stipulated by different transmission probabilities for different electron subbands in the channel. If the defect is placed on the axis of the channel then the odd electron subbands are not reflected by the defect since corresponding wave function vanishes at the point of the scatterer. Thus the photon-induced transitions between electron subbands of different parity can either increase or decrease the transmission probability. The probability of photon-induced transition depends on the distance from the channel edge to the defect. Therefore, the direct current arises in the case of asymmetric scatterer position. We have shown that the photocurrent oscillates as a function of chemical potential. The direction of the current is determined by the number of occupied subbands of different parity. The sequence of oscillating minima and maxima is changed if the scatterer is placed aside the channel axis. The photocurrent is proportional to the intensity of radiation and grows with increase of the lifetime $\tau$. The amplitude of oscillations reaches maximum when the frequency $\omega$ of radiation coincides with the characteristic frequency $\omega_0$ of the confining potential in the channel. This feature of the system gives the possibility to vary the resonance frequency by changing the geometry of the channel.

ACKNOWLEDGEMENTS

The authors are grateful to V. A. Margulis for helpful discussions. The work has been supported by Grant of the President of the Russian Federation for young scientists (grant MK-4480.2007.2) and by Russian Foundation for Basic Research (grant 08-02-01035).

APPENDIX

To obtain the transmission amplitude $t_{nn'}^{RR}$ from the left to the right reservoir we have to compare the asymptotics of the wave function at the left and the right edge of the
channel. The wave function $\psi_{\pm 1}$ is given by Eq. (14). We take the incident wave $\phi_0$ from the left reservoir in the form Eq. (18). Using Eq. (16) for $\psi_0$ and Eq. (20) for $G_d$ we may represent the function $\psi_{\pm 1}$ as a sum of four terms

$$\psi_{\pm 1}(r) = \psi^{(1)}(r) + \psi^{(2)}(r) + \psi^{(3)}(r) + \psi^{(4)}(r), \quad (42)$$

where functions $\psi^{(j)}(r)$ are given by

$$\psi^{(1)}(r) = - \int G_0(r, r'; F \pm i\hbar) \hat{V}_0 \phi_0(r', F) dr', \quad (43)$$

$$\psi^{(2)}(r) = \frac{G_0(r, r_d, F \pm i\hbar)}{Q(r_d, F \pm i\hbar) - P} \int G_0(r_d, r'; F \pm i\hbar) \hat{V}_0 \phi_0(r', F) dr', \quad (44)$$

$$\psi^{(3)}(r) = \frac{\phi_0(r_d, F) G_0(r, r_d, F \pm i\hbar)}{Q(r_d, F) - P Q(r_d, F \pm i\hbar) - P} \int G_0(r, r'; F \pm i\hbar) \hat{V}_0 G_0(r', r_d; F) dr', \quad (45)$$

$$\psi^{(4)}(r) = - \frac{\phi_0(r_d, F) G_0(r, r_d, F \pm i\hbar)}{Q(r_d, F) - P Q(r_d, F \pm i\hbar) - P} \int G_0(r, r'; F \pm i\hbar) \hat{V}_0 G_0(r', r_d; F) dr'. \quad (46)$$

Taken into consideration properties of oscillator functions $\Phi_n$ we have

$$\hat{p}_y \Phi_n(y) = i\hbar \left\{ \sqrt{\frac{n+1}{2}} \Phi_{n+1}(y) - \sqrt{\frac{n}{2}} \Phi_{n-1}(y) \right\}. \quad (47)$$

Using Eqs. (18), (19), and (47) we obtain

$$\hat{V}_0 \phi_0(r') = \frac{ie e h}{\sqrt{8m\omega a}} \left\{ \sqrt{n+1} \Phi_{n+1}(y') - \sqrt{n} \Phi_{n-1}(y') \right\} [\theta(x') - \theta(x' - L)] \exp(ik_0^0 x'), \quad (48)$$

$$\hat{V}_0 G_0(r', r_d; F) = \frac{e e}{\sqrt{8m\omega a}} [\theta(x') - \theta(x' - L)] \sum_{n'=0}^{\infty} \left\{ \sqrt{n} \Phi_{n-1}(y') - \sqrt{n+1} \Phi_{n+1}(y') \right\} \frac{\exp(ik_0^0 |x' - x_d|)}{ak_n^0}. \quad (49)$$

Now we substitute Eqs. (48) and (49) into Eqs. (43) - (46) and perform the integration over $r'$. One can see that integration over $x'$ includes only finite interval due to the $\theta$-functions. Integration over $y'$ may be performed easily due to the orthogonality of the oscillator functions $\Phi_n(y)$. For example, integration in equation (48) gives for $x \geq L$

$$\psi^{(1)}(r) = \frac{e e}{\sqrt{8m\omega a}} \sum_{n'=0}^{\infty} \left\{ \sqrt{n+1} \delta_{n',n+1} - \sqrt{n} \delta_{n',n-1} \right\} \frac{\Phi_{n'}(y)}{ak_n^0} \exp(i k_n^0 x) \int_0^L dx' \exp[i(k_{n'} - k_0^0) x'] \quad (50)$$

Then we obtain the following form for functions $\psi^{(j)}$ at the right edge of the channel ($x \geq L$)

$$\psi^{(j)}(r) = \frac{e e a}{\sqrt{8m\omega a}} \sum_{n'=0}^{\infty} t_{n'n}^{(j)} \Phi_{n'}(y) \exp(i k_n^0 x), \quad (51)$$

where coefficients $t_{n'n}^{(j)}$ are given by Eqs. (22) - (25). It should be mentioned that we have to take into account the exponential factor $\exp(i k_n^0 L)$ in the transmission amplitude since we deal with complex quasienergies and consequently complex wave numbers $k$. This factor does not vanish during the current calculation hence it should be conserved in the equation for transmission amplitude.

To get the transmission amplitude $t_{nn'}^{LR}$ from the right to the left reservoir we need do consider incident wave that is injected from the right edge of the channel and propagate to the left edge. One can see that the computation remains the same if we invert the direction of
the $x$ axis. Therefore the final expressions for transmission amplitude may be obtained from Eqs. (22)–(25) by

replacement of $x_d$ with $L - x_d$.
