Discrete hyperbolic curvature flow in the plane

Klaus Deckelnick† Robert Nürnberg‡

Abstract

Hyperbolic curvature flow is a geometric evolution equation that in the plane can be viewed as the natural hyperbolic analogue of curve shortening flow. It was proposed by Gurtin and Podio-Guidugli (1991) to model certain wave phenomena in solid-liquid interfaces. We introduce a semidiscrete finite difference method for the approximation of hyperbolic curvature flow and prove error bounds for natural discrete norms. We also present numerical simulations, including the onset of singularities starting from smooth strictly convex initial data.

Key words. hyperbolic curvature flow, normal parameterization, finite differences, error analysis

1 Introduction

The analytical and numerical study of parabolic geometric evolution equations, such as mean curvature flow, surface diffusion and Willmore flow, to name a few, has received considerable attention in the literature over the last few decades, see e.g. [19, 14, 7, 22, 21, 6, 5, 2, 8, 18, 1]. On the other hand, hyperbolic evolution laws for moving interfaces have been studied far less. In this paper, we are going to investigate the numerical approximation of the hyperbolic geometric evolution equation

\[ \alpha \partial^2_t V_{\Gamma} + \beta V_{\Gamma} = \kappa_{\Gamma} \quad \text{on } \Gamma(t), \]  

(1.1)

for a family of closed curves \((\Gamma(t))_{t \in [0,T]}\) in \(\mathbb{R}^2\). Here \(V_{\Gamma}\) denotes the velocity of \((\Gamma(t))_{t \in [0,T]}\) in the direction of the normal \(n_{\Gamma}\), \(\partial^2_t\) is the normal time derivative on \((\Gamma(t))_{t \in [0,T]}\), and \(\kappa_{\Gamma}\) denotes the curvature of \(\Gamma(t)\). Our sign convention is such that the unit circle with outward normal has curvature \(\kappa_T = -1\). The flow (1.1) corresponds to the evolution law proposed in [11, (1.2)], in the case of an isotropic surface energy and in the absence of external forcings, where it was suggested as a model for the evolution of melting-freezing waves at the solid-liquid interface of crystals such as \(^4\)He helium. Here the parameters \(\alpha \in \mathbb{R}_{\geq 0}\) and \(\beta \in \mathbb{R}_{\geq 0}\) play the role of an effective density and a kinetic coefficient, respectively. In the special case \(\alpha = 1\) and \(\beta = 0\) we obtain the hyperbolic geometric evolution law

\[ \partial^2_t V_{\Gamma} = \kappa_{\Gamma} \quad \text{on } \Gamma(t), \]  

(1.2)

while the choices $\alpha = 0$ and $\beta = 1$ yield the well-known (mean) curvature flow, or curve shortening flow. However, since in this work we are interested in the hyperbolic case, we shall from now on set $\alpha = 1$ for simplicity. We remark that in order to close the geometric evolution equation (1.1), the initial conditions

$$\Gamma(0) = \Gamma_0 \quad \text{and} \quad V_{\Gamma}|_{t=0} = V_{\Gamma,0}$$

need to be prescribed, where $\Gamma_0$ defines the initial curve and $V_{\Gamma,0} : \Gamma_0 \to \mathbb{R}$ gives an initial normal velocity.

Let us consider a parametric description of the evolving curves, i.e. $\Gamma(t) = x(I, t)$ for some mapping $x : I \times [0, T] \to \mathbb{R}^2$, where $I = \mathbb{R}/\mathbb{Z}$ is the periodic interval $[0, 1]$. We denote by

$$\tau = \frac{x_p}{|x_p|}, \quad \nu = \tau^\bot = \frac{x_p^\bot}{|x_p|}, \quad \kappa = \frac{x_p}{|x_p|},$$

the unit tangent, the unit normal and the curvature vector, respectively, so that e.g. $\nu = \nu_{\Gamma} \circ x$ and $\kappa = \kappa_{\Gamma} \circ x$. Here and throughout $\cdot^\bot$ denotes the anti-clockwise rotation through $\frac{\pi}{2}$. We shall show in Lemma 2.1 below that if $x$ is a solution of the system

$$\begin{align*}
x_{tt} + \beta x_t &= \frac{1}{|x_p|} \left( \frac{x_p}{|x_p|} \right) \nu - (x_t \cdot \tau_\tau) \tau \quad \text{in } I \times (0, T], \\
x(t, 0) &= x_0, \quad x_t(t, 0) = V_0 \nu(t, 0) \quad \text{in } I,
\end{align*}$$

(1.4a)

then the curves $(\Gamma(t))_{t \in [0, T]}$ evolve according to (1.1) with $\alpha = 1$. In the above, $x_0 : I \to \mathbb{R}^2$ is a parameterization of the given initial curve $\Gamma_0$ and $V_0 = V_{\Gamma,0} \circ x_0$ is induced by the given initial normal velocity $V_{\Gamma,0}$. The introduction of the second term on the right hand side of (1.4a) has the effect that the parameterization $x$ is normal, i.e. it satisfies $x_t \cdot \tau = 0$, see also Lemma 2.1. The system (1.4) in the case $\beta = 0$ has been studied in [15, 16], see also [12]. In particular, it is shown in [15] that if $\Gamma(0)$ is strictly convex, and if the initial velocity $V_0 \nu(\cdot, 0)$ does not point outwards anywhere on $\Gamma(0)$, then the solution to (1.4) exists on a finite time interval $[0, T_{\max})$ and the curves $\Gamma(t)$ remain strictly convex. Furthermore, as $t \to T_{\max}$, $\Gamma(t)$ either shrinks to a point or converges to a convex curve with discontinuous curvature.

One may wonder whether it is possible to replace (1.4a) by the simpler hyperbolic equation

$$x_{tt} = \frac{1}{|x_p|} \left( \frac{x_p}{|x_p|} \right) \nu \quad \text{in } I \times (0, T],$$

(1.5)

which has been considered in e.g. [13] after having been proposed by Yau in [23, p. 242]. However, in contrast to (1.4), it is not clear whether solutions to (1.5) with the initial conditions (1.4b) parameterize solutions to the flow (1.2). In fact, numerical evidence in Section 5.4, below, suggests that solutions to (1.4) and (1.5), (1.4b) parameterize different curve evolutions.

An alternative hyperbolic geometric evolution equation, that is similar to (1.4), and which has been considered in [17], is described by

$$x_{tt} = \frac{1}{2} |x_t|^2 + 1 \frac{1}{|x_p|} \left( \frac{x_p}{|x_p|} \right) \nu - (x_t \cdot \tau_\tau) \tau \quad \text{in } I \times (0, T], \quad x(\cdot, 0) = x_0, \quad x_t(\cdot, 0) = V_0 \nu(\cdot, 0) \quad \text{in } I, \quad (1.6)$$
It can be shown that solutions to (1.6) also represent normal parameterizations of curves. An interesting aspect of (1.6) in terms of the analysis is that its solutions satisfy the energy conservation
\[ \frac{1}{2} \frac{d}{dt} \int_I (|x_t|^2 + 1)|x_\rho| \, d\rho = 0. \]
In contrast, for the flow (1.4) a conditional decay property can be shown for the energy \( \frac{1}{2} \int_I (|x_t|^2 + 2)|x_\rho| \, d\rho \), see Remark 2.2 below, something that we will utilize for the numerical analysis presented in this paper. Let us finally mention that geometric second order hyperbolic PDEs have recently been used in [3] for applications in image processing.

As regards the numerical approximation of hyperbolic geometric evolution equations in the literature, we are only aware of the works [20] and [9]. In the former an algorithm for the evolution of polygonal curves under crystalline hyperbolic curvature flow is presented, which corresponds to (1.1) for a crystalline, anisotropic surface energy. On the other hand, in [9] a level-set approach, which is based on a threshold algorithm of BMO type, is used for the numerical solution of (1.5).

In this paper we will present a finite difference approximation of (1.4) and prove an error bound for it. To the best of our knowledge this is the first result on the numerical analysis for a hyperbolic geometric evolution equation in the literature.

The remainder of the paper is organized as follows. In Section 2 we show that curves \( \Gamma(t) \) that are parameterized by solutions of (1.4) evolve according to (1.1). We also derive several properties of these solutions. In Section 3 we introduce our semidiscrete finite difference approximation and state our main result, Theorem 3.5. Its proof is presented in Section 4. Finally, in Section 5 we suggest a fully discrete scheme and present several numerical simulations for it, including a convergence experiment and simulations that lead to nonvanishing singularities in finite time.

2 Mathematical formulation

Consider a family \( (\Gamma(t))_{t \in [0,T]} \) of evolving curves that are given by \( \Gamma(t) = x(I,t) \), where \( x : I \times [0,T] \to \mathbb{R}^2 \) satisfies \( |x_\rho| > 0 \) in \( I \times [0,T] \). Then the unit normal on \( \Gamma \), the curvature of \( \Gamma \), the normal velocity of \( \Gamma \) as well as the normal time derivative on \( \Gamma \) are defined by the following identities in \( I \), see e.g. [1]:

\[ \nu_{\Gamma} \circ x = \nu, \quad \kappa_{\Gamma} \circ x = \kappa, \quad V_{\Gamma} \circ x = x_t \cdot \nu, \quad (\partial_t^2 f) \circ x = (f \circ x)_t - (f \circ x)_s x_t \cdot \tau, \]

(2.1)

where \( \partial_s = |x_\rho|^{-1} \partial_\rho \) denotes differentiation with respect to arclength \( s \). We stress that the definitions of the above quantities are independent of the chosen parameterization. The following lemma establishes the connection to the evolution law (1.1) and derives additional properties of \( x \) that will be useful in the subsequent analysis.

**Lemma.** 2.1. Suppose that \( x : I \times [0,T] \to \mathbb{R}^2 \) is a solution of (1.4). Then the curves \( (\Gamma(t))_{t \in [0,T]} \) with \( \Gamma(t) = x(I,t) \) evolve according to (1.1). Furthermore, \( x \) is a normal parameterization, i.e.

\[ x_t \cdot \tau = 0 \quad \text{in} \quad I \times [0,T] \]

(2.2)

and satisfies

\[ \partial_t |x_\rho| = -|x_\rho| x_t \cdot x_{tt} - \beta |x_\rho| |x_t|^2 \quad \text{in} \quad I \times [0,T]. \]

(2.3)
Proof. Using (1.4a) and (1.3) we deduce that
$$(x_t \cdot \tau)_{t} = x_{tt} \cdot \tau + x_t \cdot \tau_t = (x_t \cdot \nu - (x_t \cdot \tau) \tau - \beta x_t) \cdot \tau + x_t \cdot \tau_t = -\beta x_t \cdot \tau.$$  
In view of (1.4b) we have \((x_t \cdot \tau)|_{t=0} = 0\) which implies (2.2). With the help of (2.1) and (2.2) we now deduce
$$(\partial_t^2 \nu_T) o x + \beta \nu_T o x = [(x_t \cdot \nu) t - (x_t \cdot \nu) x_t \cdot \tau] + \beta x_t \cdot \nu$$
$$= x_{tt} \cdot \nu + x_t \cdot \nu_t + \beta x_t \cdot \nu = x_{tt} \cdot \nu + \beta x_t \cdot \nu$$
$$= \nu \cdot \nu = \nu = \partial_t^2 \nu_T o x \quad \text{in} \ I \times [0, T],$$
where we used that \(0 = \frac{1}{2}(\nu^2)_{t} = \nu_t \cdot \nu, (1.3)\) and (1.4a). Thus (1.1) holds on \(\Gamma(t)\). Finally, recalling again (2.2) and (1.4a), we obtain
$$\partial_t |x_t| = x_{tt} \cdot \tau = -x_t \cdot \tau_t = -|x_t| |x_{tt} - \beta |x_t| |x_t|^2 \quad \text{in} \ I \times [0, T], \quad (2.4)$$
which proves (2.3). \(\square\)

Remark 2.2. Using (2.4) and (2.2) we derive the following energy law
$$\frac{1}{2} \frac{d}{dt} \int_I (|x_t|^2 + 2 |x_t|) \, dt = \frac{1}{2} \int_I |x_t|^2 \partial_t |x_t| \, dt + \int_I x_t \cdot x_{tt} |x_t| + \partial_t |x_t| \, dt$$
$$= -\frac{1}{2} \int_I |x_t|^2 x_t \cdot \tau_t \, dt - \beta \int_I |x_t|^2 |x_t| \, dt$$
$$= -\frac{1}{2} \int_I (x_t \cdot \nu)^2 |x_t| \, dt - \beta \int_I (x_t \cdot \nu)^2 |x_t| \, dt, \quad (2.5)$$
which corresponds to \([11, (4.6)]\) in the absence of external forces. An adaptation of this relation to the error between continuous and discrete solution will be at the heart of our error analysis.

For the remainder of the paper we make the following regularity assumptions concerning the solution \(x\).

Assumption 2.3. \(x : I \times [0, T] \to \mathbb{R}^2\) is a solution of (1.4) such that \(\partial_i^k \partial_j^l x\) exist and are continuous on \(I \times [0, T]\) for all \(i, j \in \mathbb{N} \cup \{0\}\) with \(2i + j \leq 4\). Furthermore, \(|x_t| > 0\) in \(I \times [0, T]\).

Assumption 2.3 implies in particular that there exist constants \(0 < c_0 \leq C_0\) such that
$$c_0 \leq |x_t| \leq C_0 \quad \text{in} \ I \times [0, T], \quad \max_{I \times [0, T]} (|\tau_t| + |x_t| + |x_{tt}|) \leq C_0. \quad (2.6)$$

3 Finite difference discretization

We shall employ a finite difference scheme in order to discretize (1.4) in space. To do so, let us introduce the set of grid points \(G^h := \{\rho_1, \ldots, \rho_J\} \subset I, \) where \(\rho_j = jh, \) \(j = 0, \ldots, J, \) and \(h = \frac{1}{J}\) for \(J \geq 2.\) In order to account for our periodic setting we always identify \(\rho_0\) with \(\rho_J.\) For a grid function \(v : G^h \to \mathbb{R}^2\) we write \(v_j := v(\rho_j), \) \(j = 1, \ldots, J,\) and in addition set \(v_0 = v_1\) and \(v_{J+1} = v_1\) in view of the periodicity of \(I.\) We associate with \(v\) the backward difference quotient:
$$\delta v_j := \frac{v_j - v_{j-1}}{h}, \quad j = 1, \ldots, J \quad (3.1)$$
and introduce the following discrete norms

\[ \|v\|_{0,h} := \left( h \sum_{j=1}^{J} |v_j|^2 \right)^{\frac{1}{2}}, \quad \|v\|_{1,h} := \left( h \sum_{j=1}^{J} (|v_j|^2 + |\delta v_j|^2) \right)^{\frac{1}{2}}. \] (3.2)

Let \( x^h : G^h \rightarrow \mathbb{R}^2 \) be a grid function that will play the role of a discrete parameterization of a curve. Then on \( I_j = [\rho_{j-1}, \rho_j] \), the associated discrete length element \( q_j^h \) and the discrete tangent \( \tau_j^h \) are given by

\[ q_j^h = |\delta x_j^h|, \quad \tau_j^h = \frac{1}{q_j^h} \delta x_j^h, \quad j = 1, \ldots, J. \]

It will be convenient to also introduce the averaged vertex tangent \( \theta_j^h \) via

\[ \theta_j^h = \frac{\tau_j^h + \tau_{j+1}^h}{|\tau_j^h + \tau_{j+1}^h|}, \quad \text{provided that } \tau_j^h + \tau_{j+1}^h \neq 0, \quad j = 1, \ldots, J. \] (3.3)

Clearly,

\[ (\tau_{j+1}^h - \tau_j^h) \cdot \theta_j^h = \frac{\tau_j^h + \tau_{j+1}^h}{|\tau_j^h + \tau_{j+1}^h|} \cdot \frac{\tau_j^h + \tau_{j+1}^h}{|\tau_j^h + \tau_{j+1}^h|} = \frac{1}{|\tau_j^h + \tau_{j+1}^h|} (|\tau_{j+1}^h|^2 - |\tau_j^h|^2) = 0. \] (3.4)

**Lemma.** 3.1. Let \( x \in C^4(I; \mathbb{R}^2) \) such that \( c_0 \leq |x_\rho| \leq C_0 \) in \( I \) and set \( \tau = \frac{x_\rho}{|x_\rho|} \) as well as

\[ x_j = x(\rho_j), \quad q_j = |\delta x_j|, \quad \text{and } \tau_j = \frac{1}{q_j} \delta x_j, \quad j = 1, \ldots, J. \]

Then there exists \( h_* > 0 \) such that for all \( 0 < h \leq h_* \) and all \( j = 1, \ldots, J \) we have

\[ \frac{1}{2} c_0 \leq q_j \leq 2 C_0 \] (3.5)

and

\[ \frac{1}{2} (q_j + q_{j+1}) = |x_\rho(\rho_j)| + \mathcal{O}(h^2); \] (3.6a)

\[ \tau_j + \tau_{j+1} = 2 \tau(\rho_j) + \mathcal{O}(h^2); \] (3.6b)

\[ \frac{\tau_{j+1} - \tau_j}{h} = \tau_\rho(\rho_j) + \mathcal{O}(h^2). \] (3.6c)

**Proof.** A Taylor expansion yields

\[ \delta x_{j+1} = \frac{x_{j+1} - x_j}{h} = x_\rho + \frac{h}{2} x_{\rho \rho} + \frac{h^2}{6} x_{\rho \rho \rho} + \mathcal{O}(h^3), \]

where all the derivatives of \( x \), and \( \tau \), in this proof are evaluated at \( \rho_j \). Hence

\[ q_{j+1}^2 = |x_\rho|^2 + h x_{\rho \rho} \cdot x_\rho + \frac{h^2}{4} |x_{\rho \rho}|^2 + \frac{h^2}{3} x_{\rho \rho \rho} \cdot x_\rho + \mathcal{O}(h^3) \]

\[ = |x_\rho|^2 \left( 1 + h \frac{x_{\rho \rho}}{|x_\rho|} \cdot \tau + h^2 \left[ \frac{1}{4} \frac{|x_{\rho \rho}|^2}{|x_\rho|^2} + \frac{1}{3} \frac{x_{\rho \rho \rho} \cdot x_\rho}{|x_\rho|^2} \cdot \tau \right] + \mathcal{O}(h^3) \right), \]
and with $\sqrt{1 + \varepsilon} = 1 + \frac{1}{2}\varepsilon - \frac{1}{8}\varepsilon^2 + \mathcal{O}(\varepsilon^3)$ it therefore follows that

$$q_{j+1} = \frac{1}{|x_{j+1}|} \delta x_{j+1}^2 + \mathcal{O}(\varepsilon^3).$$

Moreover, since $\tau_{j+1} = \frac{1}{q_{j+1}} \delta x_{j+1}^2$ and $\frac{1}{1 + \varepsilon} = 1 - \varepsilon + \varepsilon^2 + \mathcal{O}(\varepsilon^3)$, we have that

$$\tau_{j+1} = \tau + \frac{h}{2} \tau + h^2 \left[ \frac{1}{6} \frac{x_{pp}}{|x_{j+1}|^2} - \frac{1}{8} \frac{x_{pp}}{|x_{j+1}|^2} \right] - \frac{1}{4} \frac{x_{pp}}{|x_{j+1}|^2} \tau + \mathcal{O}(h^3),$$

where we used that $\frac{x_{pp}}{|x_{j+1}|^2} - \frac{x_{pp}}{|x_{j+1}|^2} = \frac{x_{pp}}{|x_{j+1}|^2}$. In a similar way one finds that

$$q_j = \frac{1}{|x_j|} \left( 1 - \frac{h}{2} x_{pp} \right) \tau + h^2 \left[ \frac{1}{6} \frac{x_{pp}}{|x_j|^2} + \frac{1}{8} \frac{x_{pp}}{|x_j|^2} \right] - \frac{1}{4} \frac{x_{pp}}{|x_j|^2} \tau + \mathcal{O}(h^3);$$

$$\tau_j = \tau - \frac{h}{2} \tau + h^2 \left[ \frac{1}{6} \frac{x_{pp}}{|x_j|^2} + \frac{1}{8} \frac{x_{pp}}{|x_j|^2} \right] - \frac{1}{4} \frac{x_{pp}}{|x_j|^2} \tau + \mathcal{O}(h^3).$$

From the above we infer that (3.5) holds provided that $0 < h \leq h_*$. The estimates (3.6) also follow immediately. $\Box$

In view of (3.6a) a natural semidiscrete finite difference approximation of (1.4) is now defined as follows. Find $x^h : \mathcal{G}^h \times [0, T] \to \mathbb{R}^2$ such that

$$\ddot{x}_j^h + \beta \dot{x}_j^h = \frac{2}{q_j^h + q_{j+1}^h} \frac{\tau_{j+1} - \tau_j^h}{h} - (\dot{x}_j^h \cdot \dot{\theta}_j^h) \theta_j^h \quad \text{in } [0, T], \quad j = 1, \ldots, J; \quad (3.7a)$$

$$x_j^h(0) = x_0(\rho_j), \quad \dot{x}_j^h(0) = V_0(\rho_j) \theta_j^h(0), \quad j = 1, \ldots, J. \quad (3.7b)$$

Standard ODE theory implies that the above system has a unique solution on some interval $[0, T_h)$. Let us begin by deriving discrete analogues of (2.2) and (2.3).

**Lemma.** 3.2. Let $x^h : \mathcal{G}^h \times [0, T_h] \to \mathbb{R}^2$ be a solution of (3.7). Then we have in $[0, T_h)$ and for all $j = 1, \ldots, J$ that

$$\dot{x}_j^h \cdot \theta_j^h = 0; \quad (3.8a)$$

$$\dot{q}_j^h + \frac{1}{4} (q_{j+1}^h + q_j^h) (\dot{x}_{j-1}^h \cdot \dot{x}_j^h + \beta |\dot{x}_{j-1}^h|^2) + \frac{1}{4} (q_j^h + q_{j+1}^h) (\dot{x}_j^h \cdot \dot{x}_j^h + \beta |\dot{x}_j^h|^2) = 0. \quad (3.8b)$$

**Proof.** It follows from (3.7a), (3.4) and the fact that $|\theta_j^h| = 1$ that

$$(\dot{x}_j^h \cdot \theta_j^h) = \dot{x}_j^h \cdot \theta_j^h + \dot{x}_j^h \cdot \theta_j^h = -\beta \dot{x}_j^h \cdot \theta_j^h, \quad j = 1, \ldots, J.$$ 

Since $\dot{x}_j^h(0) \cdot \theta_j^h(0) = 0$ by (3.7b), we deduce (3.8a). In particular, $\dot{x}_j^h \cdot \theta_j^h = -\dot{x}_j^h \cdot \theta_{j+1}^h$ and hence

$$\dot{q}_j^h = \frac{\dot{x}_j^h - \dot{x}_{j-1}^h}{h} \cdot \tau_j^h = -\frac{1}{2} \dot{x}_j^h \cdot \frac{\tau_{j+1}^h - \tau_j^h}{h} - \frac{1}{2} \dot{x}_{j-1}^h \cdot \frac{\tau_{j-1}^h - \tau_j^h}{h}$$

$$= -\frac{1}{2} \dot{q}_j^h + \frac{1}{2} (q_{j+1}^h + q_j^h) (\dot{x}_j^h \cdot \dot{x}_j^h + \beta |\dot{x}_j^h|^2) - \frac{1}{2} (q_j^h + q_{j+1}^h) (\dot{x}_{j-1}^h \cdot \dot{x}_{j-1}^h + \beta |\dot{x}_{j-1}^h|^2),$$

where the last equation is a consequence of (3.7a) and (3.8a). This proves (3.8b). $\Box$

We also have the following discrete analogue of Remark 2.2, where for simplicity we consider only the case $\beta = 0$. 

6
Lemma 3.3. Let \( x^h : \mathbb{R}^2 \times \{0, T_h\} \rightarrow \mathbb{R}^2 \) be a solution of (3.7) with \( \beta = 0 \). Then we have in \([0, T_h]\) that
\[
\frac{1}{2} \frac{d}{dt} h \sum_{j=1}^J \left( \frac{1}{2} (q_j^h + q_{j+1}^h) |\dot{x}_j^h|^2 + 2q_j^h \right) = \frac{1}{2} h \sum_{j=1}^J \frac{1}{2} \dot{q}_j^h \left( |\dot{x}_{j-1}^h|^2 + |\dot{x}_j^h|^2 \right), \tag{3.9}
\]
with \( \dot{q}_j^h \) satisfying (3.8b).

Proof. We compute, on noting (3.7a) and (3.8a), that
\[
\frac{1}{2} \frac{d}{dt} h \sum_{j=1}^J \left( \frac{1}{2} (q_j^h + q_{j+1}^h) |\dot{x}_j^h|^2 \right) = \frac{1}{2} h \sum_{j=1}^J \frac{1}{2} (q_j^h + q_{j+1}^h) |\dot{x}_j^h|^2 + h \sum_{j=1}^J \frac{1}{2} (q_j^h + q_{j+1}^h) \dot{x}_j^h \cdot \ddot{x}_j^h
\]
\[
= \frac{1}{2} h \sum_{j=1}^J \frac{1}{2} (|\dot{x}_{j-1}^h|^2 + |\dot{x}_j^h|^2) + h \sum_{j=1}^J \frac{1}{2} (q_j^h + q_{j+1}^h) \dot{x}_j^h \cdot \ddot{x}_j^h
\]
\[
= \frac{1}{2} h \sum_{j=1}^J \frac{1}{2} (|\dot{x}_{j-1}^h|^2 + |\dot{x}_j^h|^2) - h \sum_{j=1}^J \frac{\tau_j^h - \tau_{j+1}^h}{h} \dot{x}_j^h \cdot \ddot{x}_j^h
\]
\[
= \frac{1}{2} h \sum_{j=1}^J \frac{1}{2} (|\dot{x}_{j-1}^h|^2 + |\dot{x}_j^h|^2) - \frac{d}{dt} h \sum_{j=1}^J \dot{q}_j^h. \tag{3.10}
\]
Combining (3.10) with (3.8b) then yields the desired result (3.9). \( \square \)

Observe that the right hand side of (3.9), in view of (3.8b), approximates the expression
\[
- \frac{1}{2} \int \rho (x_t \cdot \nu x_t)|x_t|^2 \, d\rho = - \frac{1}{2} \int \rho (\nabla x_t \cdot \nu)|x_t|^2 \, d\rho, \tag{3.11}
\]
where we have noted (1.4a), (1.3) and (2.2). As (3.11) agrees with the right hand side in (2.5) with \( \beta = 0 \), recall again (2.2), Lemma 3.3 can be viewed as a discrete analogue of Remark 2.2.

We stress that utilizing a suitable analogue of (3.9) will be at the heart of our error analysis in Section 4, below. In particular, \( \dot{x}_j^h \) will be replaced by the time derivative of the error between \( x \) and \( x^h \) at the point \( \rho_j \).

Let us next consider the consistency errors for the scheme (3.7a) and for the property (3.8b).

Lemma 3.4. Let \( x \) be the solution of (1.4). Define
\[
R_j := \ddot{x}_j + \beta \dot{x}_j - \frac{2}{q_j + q_{j+1}} \frac{\tau_{j+1}^h - \tau_j^h}{h} + (\dot{x}_j \cdot \nu)(\rho_j, \cdot) \tau(\rho_j, \cdot); \tag{3.12a}
\]
\[
\tilde{R}_j := \ddot{x}_j + \frac{1}{2} (q_j - q_{j+1}) (\dot{x}_j - \dot{x}_{j-1}) + \beta |\dot{x}_j|^2 + \frac{1}{2} (q_j + q_{j+1}) (\dot{x}_j \cdot \ddot{x}_j + \beta |\dot{x}_j|^2). \tag{3.12b}
\]
Then there exists a constant \( C_1 \) such that
\[
\max_{j=1, \ldots, n} \left( |R_j(t)| + |\tilde{R}_j(t)| \right) \leq C_1 h^2, \quad t \in [0, T]. \tag{3.13}
\]

Proof. The bound on \( R_j \) is a direct consequence of Lemma 3.1. In order to analyze \( \tilde{R}_j \) we deduce from (3.6c) that \( \tau_{j \pm 1} = \tau_j \pm h\nu_{\rho}(\rho_j, \cdot) + O(h^2) \), and hence by (3.6b)
\[
\tau_j = \frac{\tau_j + \tau_{j+1}}{2} + \frac{\tau_{j-1} + \tau_j}{2} + O(h^2) = \frac{1}{2} (\tau(\rho_j, \cdot) + \tau(\rho_{j-1}, \cdot)) + O(h^2).
\]

7
Combining this relation with the fact that
\[
\frac{\dot{x}_j - \dot{x}_{j-1}}{h} = \frac{1}{2} (x_{tp}(\rho_{j-1}, \cdot) + x_{tp}(\rho_j, \cdot)) + \mathcal{O}(h^2)
\]
we obtain
\[
\dot{q}_j = \frac{\dot{x}_j - \dot{x}_{j-1}}{h} \cdot \tau_j = \frac{1}{2} (x_{tp}(\rho_{j-1}, \cdot) + x_{tp}(\rho_j, \cdot)) \cdot (\tau(\rho_{j-1}, \cdot) + \tau(\rho_j, \cdot)) + \mathcal{O}(h^2)
\]
In view of (2.3) we expect second order convergence for our scheme. As our main result
we prove that this is indeed the case, where the error is measured in discrete integral norms that
are natural for a second order system of hyperbolic PDEs.

**Theorem.** Suppose that Assumption 2.3 is satisfied. Then there exists \( h_0 > 0 \) such that
for \( 0 < h \leq h_0 \) the problem (3.7) has a unique solution \( x^h : \mathcal{G}^h \times [0, T] \to \mathbb{R}^2 \) and the following
error bounds hold:
\[
\max_{0 \leq t \leq T} (\|x(t) - x^h(t)\|_{1,h} + \|\dot{x}(t) - \dot{x}^h(t)\|_{0,h}) \leq C h^2.
\]

(3.14)

Here, and throughout, \( C \) denotes a generic positive constant independent of the mesh parameter \( h \).

## 4 Proof of Theorem 3.5

Let us abbreviate
\[
x_j(t) = x(\rho_j, t), \quad q_j(t) = |\delta x_j(t)|, \quad \text{and} \quad \tau_j(t) = \frac{1}{q_j(t)} \cdot \delta x_j(t), \quad j = 1, \ldots, J,
\]
where \( x \) denotes the solution of (1.4). Furthermore, we let
\[
\hat{T}_h = \sup \left\{ \hat{t} \in [0, T] : x^h \text{ solves (3.7) on } [0, \hat{t}], \right. \text{ with } \frac{1}{4} c_0 \leq q_j^h(t) \leq 4C_0 \text{ and } \max_{j=1, \ldots, J} \left( \| \tau_j(t) - \tau_j^h(t) \| + |\dot{x}_j(t) - \dot{x}_j^h(t)| \right) \leq h^{\frac{5}{2}} \text{ for } 0 \leq t \leq \hat{t}\}
\]

(4.1)

Here we have chosen the power \( h^{\frac{5}{2}} \) in the definition (4.1) as a convenient value between 1 and \( \frac{3}{2} \), where the latter power of \( h \) arises in the proof due to the application of an inverse inequality, see (4.21) below.

Clearly, \( \hat{T}_h > 0 \). In view of (2.6) and Lemma 3.1 we may assume that
\[
|\tau_j + \tau_{j+1}| \geq 1
\]

(4.2a)
and hence
\[ |\tau_j^h + \tau_{j+1}^h| \geq |\tau_j + \tau_{j+1}| - |\tau_j^h - \tau_j| - |\tau_{j+1}^h - \tau_{j+1}| \geq 1 - 2h^\frac{\delta}{2} \geq \frac{1}{2}; \tag{4.2b} \]
provided that \( 0 < h \leq h_* \) is sufficiently small. Thus \( \theta_j^h(t) \) is well defined for \( j = 1, \ldots, J \) and \( t \in [0, \hat{T}_h) \). Furthermore, we have:

**Lemma.** 4.1. There exists \( 0 < h_0 \leq h_* \) and a constant \( C_2 \), which only depends on \( c_0, C_0 \) and \( \beta \), such that for all \( 0 < h \leq h_0 \) and \( 0 \leq t < \hat{T}_h \)
\[
\max_{j=1,\ldots,J} \left( |\dot{x}_j^h(t)| + |\ddot{x}_j^h(t)| + |\dddot{x}_j^h(t)| + |\dddot{x}_j^h(t)| \right) \leq C_2.
\]

**Proof.** To begin, we deduce from (2.6) and (4.1) that
\[
|\dot{x}_j^h(t)| \leq |x_\ell(\rho_j, t)| + |(\dot{x}_j - \dot{x}_j^h)(t)| \leq C_0 + h^\frac{\delta}{2} \leq 2C_0,
\]
provided that \( 0 < h \leq h_0 \) with \( h_0 \) sufficiently small. Next, a straightforward calculation shows that
\[
|\dot{\tau}_j^h(t)| \leq \frac{1}{q_j}(\delta \dot{x}_j^h - (\dot{\delta} \dot{x}_j^h \cdot \tau_j^h)) \text{ and hence, on noting (4.1), (3.1) and (2.6), it holds that}
\]
\[
|\dot{\tau}_j^h(t)| \leq \frac{4}{c_0} \left( |\delta(\dot{x}_j - \dot{x}_j^h)(t)| + |\dot{x}_j(t)| \right)
\]
\[
\leq \frac{8}{c_0} \max_{1 \leq k \leq J} |(\dot{x}_k^h - \dot{x}_k)(t)| + \frac{4}{c_0} \max_{\rho \in \ell} |x_\rho(\rho, t)| \leq \frac{8}{c_0} h^\frac{\delta}{2} + \frac{4}{c_0} C_0 \leq \frac{8C_0}{c_0},
\]
provided that \( 0 < h \leq h_0 \) with \( h_0 \) sufficiently small. From this we deduce, on recalling (3.3) and (4.2b), that
\[
|\dot{\theta}_j^h(t)| \leq \frac{|\dot{\tau}_j^h(t) + \dot{\tau}_{j+1}^h(t)|}{|\dot{\tau}_j^h(t) + \dot{\tau}_{j+1}^h(t)|} \leq 2 \frac{16C_0}{c_0} = \frac{32C_0}{c_0}.
\]
In order to bound \( \dddot{x}_j^h \), we first use (3.6c), (2.6) and (4.1) to show that
\[
\left| \frac{\tau_{j+1}^h(t) - \tau_j^h(t)}{h} \right| \leq \frac{\tau_{j+1}^h(t) - \tau_j^h(t)}{h} + \frac{2}{c_0} \max_{k=1,\ldots,J} |\tau_k(t) - \tau_k^h(t)| \leq 2C_0 + 2h^\frac{\delta}{2} \leq 3C_0,
\]
provided that \( 0 < h \leq h_0 \) with \( h_0 \leq h_* \) sufficiently small. If we combine this estimate with (3.7a), (4.1) and the previously derived bounds on \( \dot{x}_j^h \) and \( \dot{\theta}_j^h \), we obtain
\[
|\dddot{x}_j^h(t)| \leq \beta |\dot{x}_j^h(t)| + \frac{2}{q_j^h(t) + q_{j+1}^h(t)} \left| \frac{\tau_{j+1}^h(t) - \tau_j^h(t)}{h} \right| + |\dddot{x}_j^h(t)| |\dddot{x}_j^h(t)|
\]
\[
\leq 2\beta C_0 + \frac{4}{c_0} 3C_0 + 2C_0 \frac{32C_0}{c_0} = 2\beta C_0 + \frac{12C_0}{c_0} + \frac{64C_0^2}{c_0}.
\]
Finally, the bound on \( \dddot{x}_j^h \) is a consequence of (3.8b) and (4.1) using now in addition the bound on \( \dddot{x}_j^h \). \( \square \)
Let us introduce the error \( e_j(t) := x_j(t) - x_j^h(t) \). We infer from (3.12a) and (3.7a) that

\[
\ddot{e}_j + \beta \dot{e}_j + \frac{2}{q_j^h + q_{j+1}^h} (\tau_{j+1} - \tau_{j+1}^h) - (\tau_j - \tau_j^h) = (\dot{x}_j^h \cdot (\tau_j^h) \tau_j^h) \tau_j^h + (\dot{x}_j^h \cdot \dot{\theta}_j^h)(\theta_j^h - \tau(\rho_j^h, \cdot)) - (\dot{e}_j \cdot \tau_j^h(\rho_j^h, \cdot)) \tau_j^h + R_j
\]

Taking the scalar product with \( \frac{h}{2}(q_j^h + q_{j+1}^h) \dot{e}_j \), summing over \( j = 1, \ldots, J \) and recalling Lemma 4.1 yields

\[
\frac{1}{2} \frac{d}{dt} \sum_{j=1}^{J} \frac{1}{2}(q_j^h + q_{j+1}^h)|\dot{e}_j|^2 + \beta h \sum_{j=1}^{J} \frac{1}{2}(q_j^h + q_{j+1}^h)|\dot{e}_j|^2 - h \sum_{j=1}^{J} \frac{(\tau_{j+1} - \tau_{j+1}^h) - (\tau_j - \tau_j^h)}{h} \cdot \dot{e}_j
\]

\[
= \frac{1}{2} h \sum_{j=1}^{J} \frac{1}{2}(q_j^h + q_{j+1}^h)|\dot{e}_j|^2 + h \sum_{j=1}^{J} \frac{1}{2}(q_j^h + q_{j+1}^h)T_j^k \cdot \dot{e}_j
\]

\[
\leq C h \sum_{j=1}^{J} |\dot{e}_j|^2 + h \sum_{k=1}^{J} \sum_{j=1}^{J} \frac{1}{2}(q_j^h + q_{j+1}^h)T_j^k \cdot \dot{e}_j.
\] (4.4)

While the above relation already provides us with some control on \( \dot{e}_j \), the treatment of the elliptic part is more difficult. This is a consequence of the fact that the operator \( \frac{1}{|\tau^h_j|} \frac{\partial}{\partial \tau} \tau^h_j \) is degenerate in tangential direction. It is therefore not possible to directly control \( \delta e_j \), which we split instead as follows:

\[
\delta e_j = \delta x_j - \delta x_j^h = q_j^h(\tau_j - \tau_j^h) + (q_j - q_j^h)\tau_j^h.
\] (4.5)

In the next step we will gain control on the difference of the tangents from the third term on the left hand side of (4.4). To do so, we essentially adapt arguments from [4, Section 5] developed for a finite element approach to the curve shortening flow. To begin, using summation by parts
together with the fact that \( \delta x_j^h = q_j^h \tau_j^h \), we derive

\[- h \sum_{j=1}^{J} \left( \tau_{j+1}^h - \tau_j^h \right) - \left( \tau_j - \tau_j^h \right) \cdot \dot{e}_j \]

\[= h \sum_{j=1}^{J} \left( \tau_j - \tau_j^h \right) \cdot \left( \dot{e}_j - \dot{e}_{j-1}^h \right) = h \sum_{j=1}^{J} \left( \tau_j - \tau_j^h \right) \cdot (\delta \dot{x}_j - \delta \dot{x}_j^h) \]

\[= h \sum_{j=1}^{J} \left( \tau_j^h \cdot \delta \dot{x}_j^h - \tau_j - \delta \dot{x}_j^h \right) + h \sum_{j=1}^{J} \left( \tau_j - \tau_j^h \right) \cdot \delta \dot{x}_j \]

\[= h \frac{d}{dt} \sum_{j=1}^{J} \left( q_j^h - \tau_j \cdot \delta \dot{x}_j \right) + h \sum_{j=1}^{J} \tau_j \cdot \delta \dot{x}_j^h + h \sum_{j=1}^{J} \left( \tau_j - \tau_j^h \right) \cdot \delta \dot{x}_j \]

\[= h \frac{d}{dt} \sum_{j=1}^{J} q_j^h (1 - \tau_j \cdot \tau_j^h) + h \sum_{j=1}^{J} \frac{d}{dq_j} \left( \delta \dot{x}_j - (\delta \dot{x}_j \cdot \tau_j) \tau_j \right) \cdot \tau_j^h + h \sum_{j=1}^{J} \left( \tau_j - \tau_j^h \right) \cdot \delta \dot{x}_j \]

\[= \frac{1}{2} h \frac{d}{dt} \sum_{j=1}^{J} q_j^h |\tau_j - \tau_j^h|^2 + h \sum_{j=1}^{J} \left( \frac{q_j - q_j^h}{q_j} \delta x_j \cdot (\tau_j - \tau_j^h) + \frac{1}{2} \frac{q_j}{q_j} (\delta x_j \cdot \tau_j) |\tau_j - \tau_j^h|^2 \right). \]

If we insert the above relation into (4.4), note that \( \beta \geq 0 \) and apply a Cauchy–Schwarz inequality together with Lemma 3.1 and (4.1), we obtain

\[\frac{1}{2} h \frac{d}{dt} \sum_{j=1}^{J} \left( \frac{1}{2} (q_j^h + q_{j+1}^h) |\dot{e}_j|^2 + q_j^h |\tau_j - \tau_j^h|^2 \right) \]

\[\leq C h \sum_{j=1}^{J} (|\dot{e}_j|^2 + (q_j - q_j^h)^2 + |\tau_j - \tau_j^h|^2) + h \sum_{k=1}^{5} \sum_{j=1}^{J} \left( \frac{1}{2} (q_j^h + q_{j+1}^h) T_j^k \cdot \dot{e}_j. \right. \]

(4.6)

Let us next consider the terms involving \( T_j^k, k = 1, \ldots, 5 \). To begin, note that (2.2) and (3.8a) imply

\[\tau(\rho_j, \cdot) \cdot \dot{e}_j = \tau(\rho_j, \cdot) \cdot (\dot{x}_j - \dot{x}_j^h) = -\tau(\rho_j, \cdot) \cdot \dot{x}_j^h = \dot{x}_j^h \cdot (\theta_j^h - \tau(\rho_j, \cdot)). \]

(4.7)

Therefore the definition of \( T_j^1 \) in (4.3) yields that

\[h \sum_{j=1}^{J} \frac{1}{2} (q_j^h + q_{j+1}^h) T_j^1 \cdot \dot{e}_j = h \sum_{j=1}^{J} \frac{1}{2} (q_j^h + q_{j+1}^h) (\dot{x}_j^h \cdot (\theta_j^h - \tau(\rho_j, \cdot))) (\dot{x}_j \cdot (\theta_j^h - \tau(\rho_j, \cdot))) \]

\[= \frac{1}{2} h \frac{d}{dt} \sum_{j=1}^{J} \frac{1}{2} (q_j^h + q_{j+1}^h) (\dot{x}_j^h \cdot (\theta_j^h - \tau(\rho_j, \cdot))) (\dot{x}_j \cdot (\theta_j^h - \tau(\rho_j, \cdot)))^2 - \frac{1}{2} h \sum_{j=1}^{J} \frac{1}{2} (q_j^h + q_{j+1}^h) (\dot{x}_j^h \cdot (\theta_j^h - \tau(\rho_j, \cdot)))^2 \]

\[- h \sum_{j=1}^{J} \frac{1}{2} (q_j^h + q_{j+1}^h) (\dot{x}_j^h \cdot (\theta_j^h - \tau(\rho_j, \cdot))) (\dot{x}_j^h \cdot (\theta_j^h - \tau(\rho_j, \cdot))) \]

\[\leq \frac{1}{2} h \frac{d}{dt} \sum_{j=1}^{J} \frac{1}{2} (q_j^h + q_{j+1}^h) (\tau(\rho_j, \cdot) \cdot \dot{e}_j)^2 + C h \sum_{j=1}^{J} |\theta_j^h - \tau(\rho_j, \cdot)|^2, \]
where in the last step we have used (4.7), as well as Lemma 4.1. Moreover, we have from (3.6b) that

\[ |\theta_j^h - \tau(\rho_j, \cdot)| \leq \frac{\tau_j^h + \tau_{j+1}^h}{|\tau_j^h + \tau_{j+1}^h|} - \frac{\tau_j + \tau_{j+1}}{|\tau_j + \tau_{j+1}|} + \frac{|\tau_j + \tau_{j+1}| - \tau(\rho_j, \cdot)}{|\tau_j + \tau_{j+1}|} \]

so that with (4.2a)

\[ |\theta_j^h - \tau(\rho_j, \cdot)|^2 \leq C(|\tau_j - \tau_j^h|^2 + |\tau_{j+1} - \tau_{j+1}^h|^2) + Ch^4. \quad (4.8) \]

In particular, it follows that

\[ h \sum_{j=1}^{J} \frac{1}{2}(q_j^h + q_{j+1}^h)T_j^2 \cdot \dot{e}_j \leq \frac{1}{2}h \frac{d}{dt} \sum_{j=1}^{J} \frac{1}{2}(q_j^h + q_{j+1}^h)(\tau(\rho_j, \cdot) \cdot \dot{e}_j)^2 + Ch \sum_{j=1}^{J} |\tau_j - \tau_j^h|^2 + Ch^4. \quad (4.9) \]

Next, we deduce with the help of Lemma 4.1, (4.1) and (4.8) that

\[ h \sum_{j=1}^{J} \frac{1}{2}(q_j^h + q_{j+1}^h)T_j^2 \cdot \dot{e}_j \leq Ch \sum_{j=1}^{J} |\theta_j^h - \tau(\rho_j, \cdot)| |\dot{e}_j| \leq Ch \sum_{j=1}^{J} (|\tau_j - \tau_j^h|^2 + |\dot{e}_j|^2) + Ch^4, \quad (4.10) \]

while in view of (3.13)

\[ h \sum_{j=1}^{J} \frac{1}{2}(q_j^h + q_{j+1}^h)(T_j^3 + T_j^5) \cdot \dot{e}_j \leq Ch \sum_{j=1}^{J} |\dot{e}_j|^2 + Ch^4. \quad (4.11) \]

Finally, with the help of (3.6c) and (2.6) we can bound

\[ h \sum_{j=1}^{J} \frac{1}{2}(q_j^h + q_{j+1}^h)T_j^2 \cdot \dot{e}_j \leq Ch \sum_{j=1}^{J} (|q_j - q_j^h| + |q_{j+1} - q_{j+1}^h|) \frac{|\tau_{j+1} - \tau_j|}{h} |\dot{e}_j| \]

\[ \leq Ch \sum_{j=1}^{J} (|q_j - q_j^h|^2 + |\dot{e}_j|^2) + Ch^4. \quad (4.12) \]

If we insert (4.9), (4.10), (4.11) and (4.12) into the estimate (4.6) we obtain, upon subtracting the first term on the right hand side of (4.9) from both sides of the inequality and on noting $|\dot{e}_j|^2 - (\dot{e}_j \cdot \tau)^2 = (\dot{e}_j \cdot \nu)^2$, that

\[ \frac{1}{2}h \frac{d}{dt} \sum_{j=1}^{J} \left( \frac{1}{2}(q_j^h + q_{j+1}^h)(\dot{e}_j \cdot \nu(\rho_j, \cdot))^2 + q_j^h |\tau_j - \tau_j^h|^2 \right) \]

\[ \leq Ch \sum_{j=1}^{J} \left( |\dot{e}_j|^2 + (q_j - q_j^h)^2 + |\tau_j - \tau_j^h|^2 \right) + Ch^4. \quad (4.13) \]
Using (4.7), (4.8) and Lemma 4.1, we have
\[ h \sum_{j=1}^{J} |\dot{e}_j|^2 = h \sum_{j=1}^{J} ((\dot{e}_j \cdot \tau(\rho_j, \cdot))^2 + (\dot{e}_j \cdot \nu(\rho_j, \cdot))^2) \]
\[ = h \sum_{j=1}^{J} (\dot{x}_j \cdot (\theta_j^h - \tau(\rho_j, \cdot)))^2 + h \sum_{j=1}^{J} (\dot{e}_j \cdot (\nu(\rho_j, \cdot))^2 \]
\[ \leq Ch \sum_{j=1}^{J} |	au_j - \tau_j^h|^2 + Ch^4 + h \sum_{j=1}^{J} (\dot{e}_j \cdot (\nu(\rho_j, \cdot))^2. \quad (4.14) \]

If we insert (4.14) into (4.13) we find
\[ \phi_h(t) \leq C_3(h^4 + \phi_h(t) + \psi_h(t)), \quad (4.15) \]

where we have abbreviated
\[ \phi_h(t) := h \sum_{j=1}^{J} (\frac{1}{2} (q_j^h + q_{j+1}^h) (\dot{e}_j \cdot \nu(\rho_j, \cdot))^2 + q_j^h |\tau_j - \tau_j^h|^2), \quad \psi_h(t) := h \sum_{j=1}^{J} (q_j - q_j^h)^2, \quad (4.16) \]

and noted (4.1).

It remains to bound the function \( \psi_h \), which controls the second part in (4.5). To do so we combine (3.12b) and (3.8b) and obtain
\[ \dot{q}_j - q_j^h = -\frac{1}{e}(q_{j-1} + q_j)(\dot{x}_j \cdot \dot{x}_j - \dot{x}_{j-1}^h \cdot \dot{x}_{j-1}^h) - \frac{1}{4}(q_j + q_{j+1})(\dot{x}_j \cdot \dot{x}_j - \dot{x}_{j-1}^h \cdot \dot{x}_{j-1}^h) \]
\[ + \frac{1}{4}(q_j - q_{j-1})(\dot{x}_{j-1}^h \cdot \dot{x}_{j-1}^h + \frac{1}{4})(q_j^h - q_j + (q_j^h - q_{j+1} + q_j + q_{j+1})) \dot{x}_j^h \cdot \dot{x}_j^h \]
\[ - \frac{1}{2} \beta(q_j - q_{j+1})(|\dot{x}_j|^2 - |\dot{x}_{j-1}^h|^2) \]
\[ + \frac{1}{8} \beta(q_j^h - q_j)(\dot{x}_{j-1}^h \cdot \dot{x}_{j-1}^h + \frac{1}{4})(q_j^h - q_j + (q_j^h - q_{j+1} + q_j + q_{j+1})) \dot{x}_j^h \cdot \dot{x}_j^h \]
\[ = -\frac{1}{2} \partial_t \left( (q_j - q_j^h)(|\dot{x}_j|^2 - |\dot{x}_{j-1}^h|^2) \right) + \frac{1}{8} \partial_t(q_j^h - q_j)(|\dot{x}_j|^2 - |\dot{x}_{j-1}^h|^2) \]
\[ + \frac{1}{2} \beta(q_{j-1} + q_j)(|\dot{x}_{j-1}^h|^2 - |\dot{x}_{j-1}^h|^2) - \frac{1}{2} \beta(q_j + q_{j+1})(|\dot{x}_j|^2 - |\dot{x}_{j-1}^h|^2) \]
\[ + \frac{1}{8} \beta(q_j^h - q_j + q_j^h)(|\dot{x}_{j-1}^h|^2 - |\dot{x}_{j-1}^h|^2) \]
\[ = \frac{1}{2} \beta(q_{j-1} + q_j)(|\dot{x}_{j-1}^h|^2 - |\dot{x}_{j-1}^h|^2) \quad (4.17) \]

Recalling (1.4b) and (3.7b) we infer that \( q_j^h(0) = q_j(0) \) as well as
\[ |\dot{e}_j(0)| = |\dot{x}_j(0) - \dot{x}_j^h(0)| \leq |\nu_0(\rho_j)(\tau(\rho_j, 0) - \frac{\tau_j(0) + \tau_j+1(0)}{|\tau_j(0) + \tau_j+1(0)|}) | \leq Ch^2 \quad (4.18) \]

where we also made use of (3.6b). Thus we obtain after integrating (4.17) in time, on noting
that \( ||a^2 - |b|^2|| \leq (|a| + |b|)|a - b| \) and on taking into account Lemma 4.1 and (3.13), that

\[
|q_j(t) - q_j^h(t)| \leq C(|\dot{e}_{j-1}(t)| + |\dot{e}_j(t)|) + C \int_0^t |\dot{e}_{j-1}(u)| + |\dot{e}_j(u)| \, du \\
+ C \int_0^t |(q_j - q_j^h)(u)| + |(q_j - q_j^h)(u)| + |(q_{j+1} - q_{j+1}^h)(u)| \, du + Ch^2 \\
\leq C(|\dot{e}_{j-1}(t)| + |\dot{e}_j(t)|) + C \left( \int_0^t |\dot{e}_{j-1}(u)|^2 + |\dot{e}_j(u)|^2 \, du \right)^{\frac{1}{2}} \\
+ C \left( \int_0^t |(q_j - q_j^h)(u)|^2 + |(q_j - q_j^h)(u)|^2 + |(q_{j+1} - q_{j+1}^h)(u)|^2 \, du \right)^{\frac{1}{2}} + Ch^2.
\]

Taking the square and summing over \( j \) yields

\[
h \sum_{j=1}^J (q_j - q_j^h)^2(t) \leq Ch \sum_{j=1}^J |\dot{e}_j(t)|^2 + C \int_0^t h \sum_{j=1}^J |\dot{e}_j(u)|^2 \, du + Ch \int_0^t (q_j - q_j^h)^2(u) \, du + Ch^4,
\]

which together with (4.14) and (4.1) implies

\[
\psi_h(t) \leq C_4 \left( \phi_h(t) + \int_0^t (\phi_h(u) + \psi_h(u)) \, du + h^4 \right). 
\tag{4.19}
\]

If we multiply (4.15) by \( 2C_4 \), integrate with respect to time and combine the result with (4.19), we obtain, on noting from (4.18) that \( \phi_h(0) \leq C_5 h^4 \), that

\[
C_4 \phi_h(t) + \psi_h(t) \leq (2C_4(C_3 + C_5) + C_4)(h^4 + \int_0^t \phi_h(u) + \psi_h(u) \, du),
\]

from which we deduce with the help of Gronwall’s lemma that

\[
\phi_h(t) + \psi_h(t) \leq Ch^4, \quad 0 \leq t < \hat{T}_h. 
\tag{4.20}
\]

In particular, we have for \( j = 1, \ldots, J \) and \( 0 \leq t < \hat{T}_h \) that

\[
|(\tau_j - \tau_j^h)(t)| \leq h^{-\frac{1}{2}} \left( h \sum_{k=1}^J |(\tau_k - \tau_k^h)(t)|^2 \right)^{\frac{1}{2}} \leq Ch^{-\frac{1}{2}} \sqrt{\phi_h(t)} \leq Ch^3 \leq \frac{1}{2} h^\frac{5}{2},
\]

\tag{4.21}

provided that \( 0 < h \leq h_0 \) and \( h_0 \) is chosen smaller if necessary. In a similar way, on combining (4.20), (4.16), (4.14), (3.5) and (2.6), we obtain that

\[
|\dot{e}_j - \dot{e}_j^h(t)| \leq \frac{1}{2} h^\frac{5}{2}, \quad \frac{1}{3} C_0 \leq q_j^h(t) \leq 3C_0, \quad j = 1, \ldots, J, \quad 0 \leq t < \hat{T}_h.
\]

If \( \hat{T}_h < T \) one could therefore continue the discrete solution to an interval \([0, \hat{T}_h + \varepsilon]\), for some \( \varepsilon > 0 \), such that \( \frac{1}{3} C_0 \leq q_j^h(t) \leq 4C_0, \quad |\tau_j(t) - \tau_j^h(t)| + |\dot{e}_j(t) - \dot{e}_j^h(t)| \leq h^\frac{5}{2} \) for all \( j = 1, \ldots, J \) and \( 0 \leq t \leq \hat{T}_h + \varepsilon \), contradicting the definition of \( \hat{T}_h \). Thus, \( \hat{T}_h = T \). Finally, the bounds (3.14) follow from (4.20), the definitions of \( \phi_h \) and \( \psi_h \), (4.14) and (4.5).
5 Numerical results

5.1 Fully discrete scheme

For the numerical simulations presented in this section, we consider the following fully discrete approximation of (3.7), where in order to discretize in time, we let \( t_m = m \Delta t, \ m = 0, \ldots, M \), with the uniform time step \( \Delta t = \frac{T}{M} > 0 \). We will approximate \( x^h(t_m) \) by the grid function \( x^m : \mathcal{G}^h \rightarrow \mathbb{R}^2 \). Analogously to (3.3), we define \( \theta^m_j, \ j = 1, \ldots, J \), in terms of \( x^m \), and similarly for \( q^m_j \) and \( \tau^m_j \). Then, given suitable initial data \( x^0, x^{-1} : \mathcal{G}^h \rightarrow \mathbb{R}^2 \), for \( m = 0, \ldots, M - 1 \) we find \( x^{m+1} : \mathcal{G}^h \rightarrow \mathbb{R}^2 \) such that, for \( j = 1, \ldots, J \),

\[
\frac{1}{2}(q^m_j + q^m_{j+1})h \left( \frac{x^m_{j+1} - 2x^m_j + x^{m-1}_j}{\Delta t^2} + \frac{1}{2} \beta(q^m_j + q^m_{j+1})h \left( \frac{x^{m+1}_j - x^{m-1}_j}{\Delta t} \right) \right)
= \frac{1}{2} \frac{\delta x^{m+1}_j}{\delta q^m_j + \delta q^m_{j+1}} - \frac{1}{2} \frac{\delta x^{m+1}_j}{\delta q^m_{j+1}} + \frac{1}{2} \frac{\delta x^{m-1}_j}{\delta q^m_j} - \frac{1}{2} \frac{\delta x^{m-1}_j}{\delta q^m_{j+1}}
- \frac{1}{2} \frac{\delta x^m_j}{\delta q^m_j} \beta \left( \frac{x^m_j - x^{m-1}_j}{\Delta t} \right) \frac{\theta^m_j - \theta^{m-1}_j}{\Delta t} \right) \frac{\theta^m_j}{\Delta t}.
\]

(5.1)

Observe that we have chosen a linear discretization, that is analogous to a mass-lumped finite element approximation of (1.4a), which uses a semi-implicit approximation of \( \frac{1}{|x|}( \frac{x}{|x|}_\rho^m ) \) in the spirit of the discretizations proposed for the linear wave equation in e.g. [10, §2.7]. We remark that in contrast to the semidiscrete setting, recall (3.8a), it does not appear possible to prove a fully discrete analogue of the crucial normal flow property (2.2) for the fully discrete scheme (5.1).

In order to derive suitable initial data for (5.1), we observe that the solution to (1.4) satisfies the Taylor expansion

\[
x(\cdot, \Delta t) = x + \Delta t x_t + \frac{1}{2}(\Delta t)^2 x_{tt} + O((\Delta t)^3)
= x + \Delta t V_0 \nu + \frac{1}{2}(\Delta t)^2 \left[ \frac{1}{|x|}( \frac{x}{|x|}_\rho ) \rho - (V_0 \nu \cdot \tau_t - \beta V_0 \nu) \right] + O((\Delta t)^3)
= x + \Delta t V_0 \nu + \frac{1}{2}(\Delta t)^2 \left[ \frac{1}{|x|}( \frac{x}{|x|}_\rho ) \rho - \frac{1}{|x|} \rho \right] V_0 V_0 \rho \tau - \beta V_0 \nu \right] + O((\Delta t)^3),
\]

(5.2)

where on the right hand side we always evaluate \( x, \tau, \nu, V_0 \) and their derivatives at \((\cdot, 0)\). Note in particular that in the last step we used that

\[
\tau_t \cdot \nu = \frac{x_t \rho}{|x|}(V_0 \nu)_\rho \cdot \nu = \frac{1}{|x|} \rho \frac{V_0 \rho}{|x|}(V_0 \nu)_\rho \cdot \nu.
\]

Inspired by (5.2) we choose as initial data

\[
x^0_j = x_0(\rho_j) \quad \text{and} \quad x^{-1}_j = x^0_j - \Delta t V_0(\rho_j) \theta^0_{j,\perp}
+ \frac{1}{2}(\Delta t)^2 \left[ \frac{1}{2} \frac{\delta x^0_{j+1}}{\delta q^0_{j+1}} - \frac{\delta x^0_{j+1} - \delta x^0_j}{q^0_{j+1} - q^0_j} \right] - V_0(\rho_j) V_0(\rho_j) \theta^0_{j,\perp} - \beta V_0 \theta^0_{j,\perp}.
\]

for \( j = 1, \ldots, J \).
We stress that all our presented numerical experiments fall within the scope of our main result, Theorem 3.5. However, for nonconvex initial data, and for convex initial data with an initial normal velocity $V_0$ such that $\max_I V_0 > 0$, a rigorous existence and regularity theory for the underlying PDE appears to be still lacking.

5.2 Convergence experiment

Our first set of numerical experiments is for the evolution of an initially circular curve when $\beta = 0$. It can be shown that a family of circles with radius $r(t)$ is a solution to (1.2) with $V_\Gamma|_{t=0} = V_0 \in \mathbb{R}$ for the initial outer normal velocity, if

$$\ddot{r}(t) = -\frac{1}{r(t)} \ln (0, T), \quad r(0) = r_0, \quad \dot{r}(0) = V_0.$$ 

Upon integration we obtain that

$$\frac{1}{2}(\dot{r}(t))^2 = \ln r_0 - \ln r(t) + \frac{1}{2}V_0^2 = \ln \frac{r_0}{r(t)} + \frac{1}{2}V_0^2.$$ 

Hence

$$\dot{r}(t) = \pm \sqrt{2\ln \frac{r_0}{r(t)} + V_0^2},$$

which means that if $V_0 > 0$, then $r(t)$ will at first increase until it hits a maximum, where $2\ln \frac{r_0}{r(t)} + V_0^2 = 0$, after which it will decrease and shrink to a point in finite time. On the other hand, if $V_0 \leq 0$ then the circle will monotonically shrink to a point.

For the special case $V_0 = 0$, and on recalling the Gauss error function

$$\text{erf}(z) = \frac{2}{\sqrt{\pi}} \int_0^z e^{-u^2} \, du, \quad \text{erf}'(z) = \frac{2}{\sqrt{\pi}} e^{-z^2},$$

we find that $r(t)$ is the solution of

$$t = \sqrt{\frac{2}{\pi}} r_0 \text{erf}\left( \sqrt{\ln \frac{r_0}{r(t)}} \right),$$

which means that

$$r(t) = r_0 \exp\left(-[\text{erf}^{-1}(\sqrt{\frac{2}{\pi}} t / r_0)]^2\right). \quad (5.3)$$

| $J$ | $\max_{m=0,\ldots,M} \|x(t_m) - x^m\|_{1,h}$ | EOC | $\max_{m=1,\ldots,M-1} \|\dot{x}(t_m) - \frac{x^{m+1} - x^m}{2\Delta t}\|_{0,h}$ | EOC |

Table 1: Errors for the convergence test for (5.4), (5.3) with $r_0 = 1$ over the time interval $[0, 1]$ for the scheme (5.1). We also display the experimental orders of convergence (EOC).
For the true solution
\[ x(\rho, t) = r(t) \begin{pmatrix} \cos g(2\pi \rho) \\ \sin g(2\pi \rho) \end{pmatrix}, \quad g(u) = u + 0.1 \sin(u), \] (5.4)
of (1.4) we compute approximations to the errors between \( x \) and \( x^h \), the solution to (3.7) with \( V_0 = 0 \), for the choice \( r_0 = 1 \) on the time interval \([0, 1]\) with the help of the fully discrete scheme (5.1). In particular, for the sequence of discretization parameters \( h = \frac{1}{J} = 2^{-k}, \ k = 5, \ldots, 11 \), we let \( \Delta t = h \) and compare the grid interpolations of \( x \) and \( \dot{x} \) to their fully discrete analogues in the discrete norms (3.2). These errors are reported in Table 1, where we observe the expected second order convergence rates from Theorem 3.5.

5.3 Numerical experiments with constant initial velocity

Throughout the remainder of the numerical results section we choose the discretization parameters \( J = 256 \) and \( \Delta t = 10^{-4} \). Moreover, we always let \( \beta = 0 \), unless stated otherwise. The curve evolutions we visualize by plotting the polygonal curves \( \Gamma^m \subset \mathbb{R}^2 \) defined by the vertices \( \{x^m_j\}_{j=1}^J \) and at times we also show the evolution of the length of these curves, defined by
\[ |\Gamma^m| = h \sum_{j=1}^J q^m_j = \sum_{j=1}^J |x^m_j - x^m_{j-1}|. \]
Moreover, we will often be interested in a possible blow-up in curvature, and so we will monitor the quantity
\[ K^m_\infty = \max_{j=1,\ldots,J} \frac{\delta \tau^m_j}{q^m_j} \]
as an approximation to the maximal value of \( |\kappa| = \frac{|\tau\rho|}{|\rho|} \), recall (1.3).

In all the numerical computations in this subsection, we will choose a constant initial velocity \( V_0(\rho) = V_0 \).

As discussed above, for an initial circle with uniform initial normal velocity \( V_0 = V_0 \), depending on the sign of \( V_0 \in \mathbb{R} \) the family of circles either expands at first and then shrinks, or shrinks immediately. We visualize these different behaviours in Figure 1. In each case we observe a smooth solution until the circles shrink to a point, meaning that \( |\Gamma^m| \) and \( 1/K^m_\infty \) approach zero at the same time.

For the next computations we choose as initial curve a mild ellipse, with major axis of length 3 and minor axis of length 2. The results for \( V_0 = 0 \) are shown in Figure 2, where we note the onset of a singularity in finite time. In particular, the curve appears to form two kinks, leading to a blow-up in curvature. When we choose the initial normal velocity as \( V_0 = 1 \), we obtain the results shown in Figure 3. Once again we observe a blow-up in curvature, although this time the curve does not exhibit two kinks. Instead it seems to approach a shape with four corners. We note that the initial ellipse at first grows towards a circle. It then shrinks while momentarily adopting an elliptic shape, but with the major and minor axes swapped with respect to the initial data. Towards the end of the evolution a more circular shape appears again, which then evolves to the limiting shape with the four corners, i.e. with four points where the curvature is...
Figure 1: Hyperbolic curvature flow starting from a unit circle. Above we show the evolution of $|\Gamma^m|$ over time for $V_0 = 0$, $V_0 = 1$ and $V_0 = -1$ (from left to right). The final times for these computations are $T = 1.25$, $T = 3.45$ and $T = 0.65$, respectively. Below we show the corresponding evolutions of $1/K^m_\infty$ over time.

discontinuous. We stress that the observed singularities in our numerical simulations are robust with respect to the choice of discretization parameters. For example, refining the discretization parameters to $J = 512$ and $\Delta t = 5 \times 10^{-5}$ gave visually indistinguishable results compared to Figure 3.

Figure 2: Hyperbolic curvature flow, with $V_0 = 0$, starting from an ellipse. On the left we show $\Gamma^m$ at times $t = 0, 0.1, \ldots, 1.4, T = 1.47$. We also show the evolutions of $|\Gamma^m|$ (middle) and $1/K^m_\infty$ (right) over time.

We are interested in the effect of the parameter $\beta$ on these developing singularities, and would expect some damping or smoothing to be observable for $\beta > 0$. Repeating the simulation from Figure 2 with $\beta = 2$ yields the results in Figure 4, where we observe that the blow-up in curvature now happens much later, when the curve itself is almost extinct. We also see a marked change in the profile of the evolving curve. While in Figure 2 at late times the curve resembles an ellipsoid aligned with the $x_2$-axis, the evolution in Figure 4 for long times appears to approach a circle, until towards the very end it starts to resemble an ellipsoid aligned with the $x_1$-axis. In addition, a repeat of Figure 3 now with $\beta = 0.1$ is shown in Figure 5, where once again we note that visually the curve appears smoother for longer, until eventually the curvature blows up due to facetting on the left and right sides of the curve.
Figure 3: Hyperbolic curvature flow, with $V_0 = 1$, starting from an ellipse. On the left we show $\Gamma^m$ at times $t = 0, 0.3, \ldots, T = 4.2$. We also show the evolutions of $|\Gamma^m|$ (middle) and $1/K^m_\infty$ (right) over time.

Finally, we also consider some numerical experiments where the initial data is nonconvex. For the simulation in Figure 6 we start from a smooth dumbbell-like initial curve. We observe that the curve starts to shrink until it eventually exhibits two facets on the left and right, which leads to a blow-up in the curvature. Repeating the simulation for the constant initial velocity $V_0 = 1$ yields the results in Figure 7. Now the curve first expands vertically into a convex curve that expands further, until it narrows on the $x_1$-axis towards the origin to create a new nonconvex shape that resembles a variant of the initial data that is now aligned with the $x_2$-axis. At this stage the curve begins again to expand into a convex shape that then shrinks until two developing kinks at the top and bottom of the curve lead to a blow-up in curvature. Interestingly, when we use the initial velocity $V_0 = -1$ the curve soon self-intersects, see Figure 8, which is something the parametric formulation is blind towards. Similarly to the evolution in Figure 6, the solution approaches a blow-up in curvature when two facets are about to be created on the left and right sides of the curve.

In conclusion we remark that the onset of a blow-up in curvature in finite time for strictly convex initial data as observed in Figure 2 confirms the theoretical predictions in [15]. In addition, Figure 3 demonstrates that the same can be observed for an outward initial velocity $V_0 \nu(\cdot, 0)$. Finally, from our remaining numerical simulations we conjecture that also nonconvex initial data can exhibit the same phenomenon.

5.4 Numerical experiments with nonconstant initial velocity

In this final subsection we report on a numerical simulation with a nonconstant initial velocity $V_0$. In particular, we repeat the experiment from Figure 3, but now choose $V_0(\rho) = \sin(2\pi \rho)$, with $x_0(\rho) = \left(\frac{3}{2} \cos(2\pi \rho), \sin(2\pi \rho)\right)^T$. The evolution can be seen in Figure 9. Note that due to the given initial velocity, the curve rises and shrinks at the same time. Towards the end of the evolution a flat patch appears to develop at the bottom part of the curve. For a later
Figure 4: Damped hyperbolic curvature flow, with $\beta = 2$ and $V_0 = 0$, starting from an ellipse. On the top we show $\Gamma^m$ at times $t = 0, 0.2, \ldots, 2.4, T = 2.4423$, as well as $\Gamma^m$ separately at times $t = 2.44$ and $t = T$. Below we show the evolutions of $|\Gamma^m|$ (left) and $1/K_{\infty}^m$ (right) over time.

In comparison, we also provide a plot of the discrete tangential velocity

$$\|D_t x^{m+1} \cdot \theta^m\|_{0,h} := \left( h \sum_{j=1}^J \left| \frac{x^{m+1}_j - x^m_j}{\Delta t} \cdot \theta^m_j \right|^2 \right)^{\frac{1}{2}}.$$

over time in Figure 9. Since (5.1) is a discrete approximation of the normal flow (1.4), the quantity stays nearly equal to zero throughout the evolution.

We mentioned in the introduction that a question of mathematical interest is whether solutions to (1.5) parameterize curves evolving according to (1.2). We now provide some numerical evidence that this is not the case. In order to numerically approximate solutions to (1.5), we naturally adapt the scheme (5.1), for $\beta = 0$, by omitting the last term on the right hand side of (5.1). For this new scheme we then repeat the computation from Figure 9 using exactly the same discrete initial data. The ensuing evolution, shown in Figure 10, is close to what we observed before, but ultimately differs. The differences are most pronounced in the final shape of $\Gamma^m$ and in the plot of $1/K_{\infty}^m$ over time. We remark that a main difference between (1.4) and (1.5) is that the former is a normal flow, while the latter allows for a nonzero tangential component of the velocity $x_t$. Once again this is confirmed by our numerical experiment, as can be seen from the plot of $\|D_t x^{m+1} \cdot \theta^m\|_{0,h}$ in Figure 10, which seems to be monotonically increasing. We remark that we repeated the simulations in Figures 9 and 10 with finer discretization parameters and obtained visually indistinguishable results. Hence we are confident that the displayed evolution provide numerical evidence that the two PDEs (1.4a) and (1.5), with the initial conditions (1.4b), parameterize different curve evolutions.
Figure 5: Damped hyperbolic curvature flow, with $\beta = 0.1$ and $V_0 = 1$, starting from an ellipse. On the left we show $\Gamma^m$ at times $t = 0, 0.3, \ldots, 3.9, T = 4.1$. We also show the evolutions of $|\Gamma^m|$ (middle) and $1/K^m_\infty$ (right) over time.

Figure 6: Hyperbolic curvature flow, with $V_0 = 0$, starting from a smooth dumbbell. On top we show $\Gamma^m$ at times $t = 0, 0.05, \ldots, 0.2, T = 0.23$. Below we show the evolutions of $|\Gamma^m|$ (left) and $1/K^m_\infty$ (right) over time.

Figure 10: The flow (1.5) with (1.4b) for \( V_0(\rho) = \sin(2\pi \rho) \), starting from an ellipse parameterized by \( x_0(\rho) = (\frac{3}{2} \cos(2\pi \rho), \sin(2\pi \rho))^T \). On the left we show \( \Gamma^m \) at times \( t = 0, 0.2, \ldots, T = 1.2 \). We also show the evolutions of \( \|D_t x^{m+1} \cdot \theta^m\|_{0,h} \) (middle) and \( 1/K^m_\infty \) (right) over time.
