Abstract

We show that the string spectrum in the pp-wave limit of \( AdS_5 \times S^5/Z_M \) (orbifolded pp-wave) is reproduced from the \( \mathcal{N} = 2 \) quiver gauge theory by quantizing the Green-Schwarz string theory on the orbifolded pp-wave in light cone gauge. We find that the twisted boundary condition on the world-sheet is naturally interpreted from the viewpoint of the quiver gauge theory. The correction of order \( g^2_{YM} \) to the gauge theory operators agrees with the result in its dual string theory. We also discuss strings on some other orbifolded pp-waves.
1 Introduction

The AdS/CFT correspondence \cite{1, 2} gives us a deep understanding of duality between string theory and gauge theory. Furthermore, from this we would know how the closed string theory can be realized in terms of non-gravitational theory. In the most interesting case $AdS_5 \times S^5$ the conjectured duality to $\mathcal{N} = 4$ super Yang-Mills theory has been checked on the supergravity level \cite{3, 4}. In order to show this in full string theory we must analyze the world-sheet theory in the presence of RR-flux. Recently, an intriguing progress has been made in this direction \cite{5}. In the papers \cite{6, 7} it was shown that the Penrose’s limit \cite{8} of $AdS_5 \times S^5$ in type IIB string theory is exactly solvable (see also related papers \cite{3, 10, 11}). The background in this limit is described by the maximally supersymmetric pp-wave (plane-fronted wave with parallel rays) with RR-flux \cite{12, 13}.

The explicit metric of pp-wave \cite{14} is given by

$$ds^2 = -4dx^+dx^- - \mu^2 \sum_{i=1}^{8}(z^i)^2(dx^i)^2 + \sum_{i=1}^{8}(dz^i)^2,$$

where we have defined the light-cone coordinate $x^\pm = \frac{x^0 \pm x^9}{2}$ and the RR-flux $F_{+1234} = F_{+5678}$ is proportional to $\mu$. Using this solvable limit the authors of \cite{5} construct the explicit map between states of the string theory in pp-wave background and the operators in the large $N$ limit of $\mathcal{N} = 4$ super Yang-Mills theory which have large $U(1)$ R-charge $J \sim N^{-\frac{1}{2}}$. These operators can be regarded as ‘almost chiral primary’ operators and the deviations from chiral primary represent stringy excitations.

In this paper we would like to consider the pp-wave limit of orbifolded $AdS_5 \times S^5$, especially $AdS_5 \times S^5/Z_M$ (see \cite{15, 16, 17, 18} for the tests of duality on the supergravity level). The orbifold action acts on the four coordinates $(z_6, z_7, z_8, z_9)$ in the background (1.1). This example is interesting because of two reasons. First we can discuss the less supersymmetric $\mathcal{N} = 2$ quiver gauge theory \cite{19, 20, 15, 16} (see also papers \cite{21, 22, 23} for the enhancement of $\mathcal{N} = 4$ supersymmetry in the pp-wave limit of $\mathcal{N} = 1$ gauge theory). Secondly an orbifold is a good example of a stringy geometry and thus it will be important to see how its structure can be seen in the gauge theory side. The duality in this orbifolded pp-wave was already implied in \cite{4} and the particular case $M = 2$ was briefly discussed in \cite{21}. Below we investigate the detailed correspondence for the $Z_M$ orbifolded string theory in both the untwisted sector and twisted sectors. In particular we explicitly quantize the world-sheet theory on the orbifolded pp-waves. This analysis reveals the interesting interpretation of the twisted boundary condition in the orbifolded world-sheet theory from the viewpoint of the $\mathcal{N} = 2$ quiver gauge theory. This enables us to see that the string spectrum is exactly matched with the gauge theory calculation.
up to order $g(\sim g^2 M)$ correction. We also mention a similar analysis for more general orbifolds.

The contents of this paper is as follows. In section two we briefly review the results in [5]. In section three we quantize the orbifolded string theory on pp-wave and discuss its correspondence with the $\mathcal{N} = 2$ quiver gauge theory. In section four we mention general orbifolds. In section five we draw conclusions.

While preparing this paper for publication, we received the preprints [24, 25] which have some overlap with ours.

## 2 String on pp-waves and $\mathcal{N} = 4$ super Yang-Mills

In [5] it was proposed that the AdS/CFT correspondence [1] in the Penrose’s limit is the duality between the string theory in the pp-wave background (1.1) and the $\mathcal{N} = 4$ super Yang-Mills theory. The near horizon limit of a system of $N$ D3-branes is described by the geometry $AdS_5 \times S^5$ and its explicit metric is given by

$$ds^2 = R^2 \left( -dt^2 \cosh^2 \rho + d\rho^2 + \sinh^2 \rho \, d\Omega_3^2 + d\psi^2 \cos^2 \theta + d\theta^2 + \sin^2 \theta d\Omega_3^2 \right), \quad (2.2)$$

where $R = (4\pi g N \alpha')^{1/4}$ is the radius of $S^5$. For this background the Penrose’s limit, which is generally defined as the limiting procedure of taking infinitely small neighborhoods of null geodesic, is given by the limit $R \to \infty$ focusing on $\rho = \theta = 0$ with the following scaling\(^3\)

$$x^+ = \frac{t + \psi}{2}, \quad x^- = \frac{R^2(t - \psi)}{2}, \quad \rho = \frac{r}{R}, \quad \theta = \frac{\theta}{R}. \quad (2.3)$$

Then we obtain exactly the pp-wave background (1.1) with $\mu = 1$.

The pp-wave background (1.1) in light-cone Green-Schwarz(GS) string theory is described by the following world-sheet Lagrangian [3, 7]

$$\mathcal{L} = \frac{1}{2} \left[ \partial_+ z^i \partial_- z^i - (2\pi \alpha' p^+ \mu)^2 (z^i)^2 \right], \quad (2.4)$$

where $z^i$ ($i = 1, 2, \cdots, 8$) are the scalar fields corresponding to the spacetime coordinates not in the light-cone direction and we omit the terms which include sixteen fermions $S^{1a}$.

\(^3\)In taking this limit one may consider that the periodicity of $\psi$ will lead to that of $x^+$. One way to see that the periodicity is not important in the Penrose’s limit is to take another Penrose’s limit discussed in [3]. We thank A.A. Tseytlin for pointing out this to us. We can show that even if we modify the scaling (2.3) such that $x^+ = \frac{t + \psi}{1 + \lambda}$ (others are not changed), we can obtain the same results (e.g. (1.1) and (2.12)) in the region $\Delta \sim J$. 

2
and $S^{a}_{n}$ ($a = 1, 2, \cdots, 8$). In this paper we mainly show the analysis of bosonic operators because the fermionic sector can be examined similarly.

An operator of conformal dimension $\Delta$ and R-charge $J$ in the gauge theory side corresponds to a state in the Green-Schwarz string which has the light-cone momentum $p^-, p^+$ by the following rule

$$2p^- = \Delta - J, \quad 2p^+ = \frac{\Delta + J}{R^2}. \quad (2.5)$$

In order to keep the value of $p^+$ and $p^-$ finite we focus on the operator $\Delta \sim J \sim N^{1/2}$ in the large $N$ limit. We always assume this scaling below in this paper.

In this duality [5] the ground state $|\text{vac}, p^- = 0, p^+ \rangle$ of string theory in pp-wave background is identified with the operator $\text{tr}[Z^J]$, which has the conformal dimension $\Delta = J$. The excitations in the string theory correspond to the insertions of fields $\Phi^i$ (4 transverse scalars), $\chi^a_{j=1/2}$ (8 fermions) or covariant derivatives $D_i$ ($i = 1, 2, 3, 4$) in $\text{tr}[Z^J]$. The map between them is roughly given as follows

$$a^{i}_{n} \rightarrow D_i Z \quad (i = 1, 2, 3, 4), \quad (2.6)$$

$$a^{j}_{n} \rightarrow \Phi^j \quad (j = 5, 6, 7, 8), \quad (2.7)$$

$$S^{a}_{n} \rightarrow \chi^a_{j=1/2} \quad (a = 1, 2, \cdots, 8), \quad (2.8)$$

where $a^{i}_{n}$ and $S^{a}_{n}$ denote the bosonic and fermionic oscillators with the level $n$ (following the convention in [5]) of the Green-Schwarz string in the light-cone gauge.

The detailed map including the level $n$ is more complicated and shows the way how the stringy excitations are translated into the gauge theoretic counterparts [5]. Let us consider the insertion of $\Phi^{ij}$ operators $s$ times into the $\text{tr}[Z^J]$ at just before $l_j$-th $Z$ and summing over $l_j$

$$\sum_{l=0}^{J-1} \prod_{i=1}^{s} \exp \left(2\pi i \frac{I_i n_i}{J} \right) \text{tr} \left( (Z)^{k_1} \Phi(Z)^{k_2} \cdots (Z)^{k_s} \Phi(Z)^{J-\sum_{i=1}^{s} k_i} \right)$$

$$= \sum_{l=0}^{J-1} \exp \left(2\pi i \frac{1}{J} \sum_{j=1}^{s} n_j \right) \prod_{i=1}^{s} \exp \left(2\pi i \frac{(l_i - l_1)n_i}{J} \right) \text{tr} \left( (Z)^{k_1} \Phi \cdots (Z)^{k_s} \Phi(Z)^{J-\sum_{i=1}^{s} k_i} \right) \quad (2.9)$$

where the value $\sum_{j=1}^{i} k_j$ is equal to the $i$-th smallest value among $l_j$'s. Then it vanishes except $\sum_{i=1}^{s} n_i = 0$ by summing up $l_i$ with fixing $l_i - l_1$ using the cyclic property of the trace. Thus we must require this relation. Even though there is an ambiguity on the correct ordering at $l_i = l_j$, it will not be important in the “dilute gas” approximation [5].
Note that if one regards the positions of $\Phi^{ij}$ as the physical positions of $s$ point particles in 1+1 dimensional spacetime $\Sigma$, the discrete Fourier transformation in (2.9) defines the ‘momentum’ $n_i$ for each particle and the relation $\sum_{i=1}^{s} n_i = 0$ is interpreted as momentum conservation. Furthermore, if we identify $\Sigma$ with the string world-sheet, then the “string of Z’s” can be regarded as the physical string as argued in [4].

In string theory side we can interpret the operator (2.9) as
\[
\prod_{j=1}^{s} (\alpha_{n_j}^{*}) |\text{vac}, 0, p^+\rangle. \tag{2.10}
\]

Note that the above state satisfies the level matching condition $\sum n_i = 0$ as expected. In string theory side we can compute the light-cone energy
\[
2p^- = \sum_{j=1}^{s} \sqrt{1 + \frac{n_j^2}{(\alpha'p^+)^2}}. \tag{2.11}
\]

The duality tells us the relation (2.3) and we obtain
\[
\Delta - J = \sum_{j=1}^{s} \sqrt{1 + \frac{4\pi g N n_j^2}{J^2}}. \tag{2.12}
\]

This prediction can be checked in the first order of the coupling constant $g$ by the calculation in the large $N$ limit of $\mathcal{N} = 4$ super Yang-Mills theory [3].

3 Strings on $Z_M$ orbifolded pp-wave and $\mathcal{N} = 2$ quiver gauge theory

The low energy limit of $N$ D3-branes on the orbifold $C^2/Z_M$ can be described by the $\mathcal{N} = 2$ quiver gauge theory [19], where the orbifold action is defined as follows
\[
(\phi_1, \phi_2) \rightarrow (e^{\frac{2\pi i}{\alpha'}} \phi_1, e^{-\frac{2\pi i}{\alpha'}} \phi_2), \tag{3.13}
\]
where $\phi_1 = z_6 + iz_7$ and $\phi_2 = z_8 + iz_9$ denote the coordinates of $C^2/Z_M$ (see (1.1)). In the near horizon limit we obtain the geometry $AdS_5 \times S^5/Z_M$ and AdS/CFT correspondence tells us the duality between this background and the $\mathcal{N} = 2$ gauge theory [15, 16, 17, 18]. The metric of this background is given by the metric (2.2) orbifolded by the $Z_M$ action only on $\Omega_3$ and the value of radius is given by $R = (4\pi g N M \alpha'^2)^{\frac{1}{4}}$ because we start with $MN$ D3-branes and further we impose the $Z_M$ projection. In this section we would like to investigate the AdS/CFT correspondence by taking the Penrose’s limit.
3.1 GS string on orbifolded pp-waves

The Penrose’s limit of \( AdS_5 \times S^5 / Z_M \) is the \( Z_M \) orbifold of the pp-wave background (1.1). Since the orbifold projection does not act on the light-cone direction, we can describe GS string theory in this background simply by taking the \( Z_M \) orbifold in the sense of world-sheet theory in light-cone gauge (refer to [3, 4] for the detailed analysis of GS string theory on pp-wave). Then the orbifold action in string theory is defined by (3.13) identifying the coordinate \( z^i \) and \( \phi_i \) with the world-sheet scalar fields.

The \( m \)-th twisted sector is defined by the following boundary condition

\[
\begin{align*}
\dot{z}^i(\sigma + 1, \tau) &= z^i(\sigma, \tau), \quad (i = 1, 2, 3, 4) \\
\phi_1(\sigma + 1, \tau) &= e^{\frac{2\pi i m}{M}} \phi_1(\sigma, \tau), \quad \phi_2(\sigma + 1, \tau) = e^{-\frac{2\pi i m}{M}} \phi_2(\sigma, \tau). \quad (3.14)
\end{align*}
\]

We have also sixteen real fermions \( S^{1a} \) and \( S^{2a} \) and they are also divided into two groups. The eight fermions in one group obey the trivial boundary condition and the other eight are twisted by the phase \( e^{-\frac{2\pi i m}{M}} \).

For example, the mode expansions of (twisted) boson \( \phi_1 \) are given by

\[
\begin{align*}
\phi_1(\sigma, \tau) &= i \sum_{n \in \mathbb{Z}} \left( \frac{1}{\omega_n} e^{2\pi i (n-\delta)\sigma - i\omega_n \tau} \alpha^{1L}_{n-\delta} + \frac{1}{\omega_n'} e^{-2\pi i (n+\delta)\sigma - i\omega_n' \tau} \alpha^{1R}_{n+\delta} \right), \\
\bar{\phi}_1(\sigma, \tau) &= i \sum_{n \in \mathbb{Z}} \left( \frac{1}{\omega_n'} e^{2\pi i (n+\delta)\sigma - i\omega_n' \tau} \bar{\alpha}^{1L}_{n+\delta} + \frac{1}{\omega_n} e^{-2\pi i (n-\delta)\sigma - i\omega_n \tau} \bar{\alpha}^{1R}_{n-\delta} \right), \quad (3.15)
\end{align*}
\]

where \( \delta = m/M \) and we can obtain the expression of \( \phi_2 \) by replacing \( \delta \) with \(-\delta\). Here we also defined

\[
\begin{align*}
\omega_n &= \pm 2\pi \sqrt{(n-\delta)^2 + (\alpha' p^\mu \mu)^2} \quad (+ \text{ for } n > 0, - \text{ for } n \leq 0) \\
\omega_n' &= \pm 2\pi \sqrt{(n+\delta)^2 + (\alpha' p^\mu \mu)^2} \quad (+ \text{ for } n \geq 0, - \text{ for } n < 0). \quad (3.16)
\end{align*}
\]

Then the usual canonical quantization of the Lagrangian (2.4) gives

\[
\begin{align*}
[\alpha^{1L}_{n-\delta}, \bar{\alpha}^{1L}_{n'+0}] &= \omega_n \delta_{n+n',0}, & [\alpha^{1R}_{n+\delta}, \bar{\alpha}^{1R}_{n'+0}] &= \omega_n' \delta_{n+n',0}, \\
[\alpha^{2L}_{n+\delta}, \bar{\alpha}^{2L}_{n'+0}] &= \omega_n' \delta_{n+n',0}, & [\alpha^{2R}_{n-\delta}, \bar{\alpha}^{2R}_{n'+0}] &= \omega_n \delta_{n+n',0}. \quad (3.17)
\end{align*}
\]

The vacuum state of the world-sheet theory in the \( m \)-th twisted sector is defined by

\[
\begin{align*}
\alpha^{1L}_{n-\delta}|\text{vac}\rangle_m &= \bar{\alpha}^{1R}_{n+\delta}|\text{vac}\rangle_m = \alpha^{2R}_{n-\delta}|\text{vac}\rangle_m = \bar{\alpha}^{2L}_{n+\delta}|\text{vac}\rangle_m = 0 \quad (n \geq 1), \\
\alpha^{1R}_{n+\delta}|\text{vac}\rangle_m &= \bar{\alpha}^{1L}_{n-\delta}|\text{vac}\rangle_m = \alpha^{2L}_{n+\delta}|\text{vac}\rangle_m = \bar{\alpha}^{2R}_{n-\delta}|\text{vac}\rangle_m = 0 \quad (n \geq 0). \quad (3.18)
\end{align*}
\]

The bosonic part of the light-cone Hamiltonian is given by
\[ H = H_0 + H_{\text{flat}} + \frac{1}{2\pi \alpha' p^+} \sum_{n=0}^{\infty} \left[ \alpha_{n-\delta}^{1L} \bar{\alpha}_{n+\delta}^{1L} + \alpha_{n-\delta}^{1R} \bar{\alpha}_{n+\delta}^{1R} \right] + \frac{1}{2\pi \alpha' p^+} \sum_{n=1}^{\infty} \left[ \bar{\alpha}_{n+\delta}^{1L} \alpha_{n-\delta}^{1L} + \bar{\alpha}_{n+\delta}^{1R} \alpha_{n-\delta}^{1R} \right] + (\phi_2 \text{ part}), \] (3.19)

where \( H_0 \) and \( H_{\text{flat}} \) denote the contributions from zero-modes and four bosons in the non-orbifold direction \((x^1, x^2, x^3, x^4)\). We omit these detailed forms because both contributions are the same as in \([7]\).

For example, the oscillators \( \alpha_{n-\delta}^{1L} \) and \( \bar{\alpha}_{n+\delta}^{1R} \) in the \( m \)-th twisted sector have the light-cone energy

\[ 2p^- = \sqrt{\mu^2 + (n + \delta)^2}. \] (3.20)

We assume that the zero-energy (or the value of \( p^- \) for the lowest state) in the twisted sector is zero and will see that the desirable spectrum is obtained in twisted sectors later. Note also that if we take the limit \( \mu \to 0 \), then we reproduce the mass spectrum of familiar string theory on the orbifold \( C^2/Z_M \).

Then the spectrum should be \( Z_M \) projected and also satisfy the level matching condition. The level is defined to be the summation of ‘\( n \pm \delta \)’ with respect to each oscillator for a given state. The level in the left-moving sector should be equal to that in the right-moving sector.

Now it is convenient to extract the creation operators and we rename them as follows

\[
\begin{align*}
\alpha_{n}^{1L} &\equiv \alpha_{n-\delta}^{1L} (n \leq 0), \quad \alpha_{n+\delta}^{1R} (n > 0), \\
\bar{\alpha}_{n}^{1L} &\equiv \bar{\alpha}_{n+\delta}^{1L} (n < 0), \quad \alpha_{n-\delta}^{1R} (n \geq 0), \\
\alpha_{n}^{2L} &\equiv \alpha_{n+\delta}^{2L} (n < 0), \quad \alpha_{n-\delta}^{2R} (n \geq 0), \\
\bar{\alpha}_{n}^{2L} &\equiv \bar{\alpha}_{n-\delta}^{2L} (n \leq 0), \quad \bar{\alpha}_{n+\delta}^{2R} (n > 0).
\end{align*}
\] (3.21)

Note also the \( Z_M \) action

\[
\begin{align*}
\alpha_{n}^{1L} &\rightarrow e^{2\pi i \delta} \alpha_{n}^{1L}, \quad \bar{\alpha}_{n}^{1L} \rightarrow e^{-2\pi i \delta} \bar{\alpha}_{n}^{1L}, \quad \alpha_{n}^{1R} \rightarrow e^{-2\pi i \delta} \alpha_{n}^{1R}, \quad \bar{\alpha}_{n}^{1R} \rightarrow e^{2\pi i \delta} \bar{\alpha}_{n}^{1R}, \\
\alpha_{n}^{2L} &\rightarrow e^{-2\pi i \delta} \alpha_{n}^{2L}, \quad \bar{\alpha}_{n}^{2L} \rightarrow e^{2\pi i \delta} \bar{\alpha}_{n}^{2L}, \quad \alpha_{n}^{2R} \rightarrow e^{2\pi i \delta} \alpha_{n}^{2R}, \quad \bar{\alpha}_{n}^{2R} \rightarrow e^{-2\pi i \delta} \bar{\alpha}_{n}^{2R},
\end{align*}
\] (3.22)

and the level of left-mover minus that of right-mover for \( \alpha_{n}^{1L}, \bar{\alpha}_{n}^{1L}, \alpha_{n}^{1R} \) and \( \bar{\alpha}_{n}^{1R} \) are given by \( n-\delta, n+\delta, n+\delta \) and \( n-\delta \), respectively. Then we can construct all states by operating these on the \( m \)-th twisted vacuum and requiring the level matching condition and invariance under the \( Z_M \) action. Note that there are two types of \( Z_M \) invariants, i.e. a product of \( M \) oscillators in (3.21) which have the same ‘\( Z_M \) charge’ of (3.22) and products of different ‘\( Z_M \) charge’ oscillators. The differences of the levels of these invariants are integer.
Finally let us briefly mention the fermionic zeromodes. The orbifold projection acts on the fermionic fields as they are space-time spinors. In untwisted sector the fermion zero modes $S_0^{a0}, S_0^{b0}, (a, b = 1, 2, \cdots, 8)$ satisfy the relation $\{S_0^{ia}, S_0^{jb}\} = \delta_{ab}\delta_{ij}$. We can quantize these and get $2^8$ “massless” states if we consider the flat space not the orbifold. In the orbifold theory the $Z_M$ acts on them as phase factor $e^{2\pi i(s_3-s_4)/M}$ where $s_3$ and $s_4$ are spin along $(x_6, x_7)$ and $(x_8, x_9)$, respectively, and $s_3, s_4 = \pm \frac{1}{2}$. In the twisted sector we have eight fermion zero modes $S_0^a$ and after the quantization we have $2^4 = 8$ bosons+8 fermions “massless” states. Four bosons parameterize the hyperkahler moduli of the vanishing cycles and the other four bosons explain the RR field moduli if we set $\mu = 0$.

3.2 $\mathcal{N} = 2$ quiver gauge theory and string spectrum

The quiver gauge theory is defined by the corresponding quiver diagram \cite{19, 20}. In our case we consider the quiver diagram of $A_{M-1}$ type, which has $M$ nodes and arrows between them. Each node represents a gauge group $U(N)$ and we denote the corresponding $i$-th vector multiplet as $(Z_i, W_i)$ in the $\mathcal{N} = 1$ superfield notation. Thus its gauge group\footnote{Note that in the context of AdS/CFT correspondence $N U(1)$ factors of $G$ will be decoupled \cite{18}.} is $G = \prod_{i=1}^{M} U(N)$. It should be also noted that the gauge coupling $g'$ of each $U(N)$ gauge theory is given by $g' = Mg$ \cite{13, 16}.

In the quiver diagram the arrow pointing one direction corresponds to the superfield $Q_1^i, Q_1^i$, which is bifundamental matters $(\bar{N}, N)$ with respect to $i$-th and $i+1$-th gauge groups, and the other arrow to $Q_2^i, \bar{Q}_1^i$. These form $M$ hyper multiplets $(Q_1^i, \bar{Q}_1^i), (i = 1, \ldots, M)$. Below we regard the index $i$ as $Z_M$ valued. The R-charges of these fields are summarized in Table 1.

| Field | $J = r/2$ | $2j$ | gauge charge |
|-------|-----------|------|--------------|
| $Z$   | 1         | 0    | adj          |
| $Q_1^1$ | 0         | 1    | $(\bar{N}, N)$ |
| $Q_2^1$ | 0         | -1   | $(N, \bar{N})$ |
| $\bar{Q}_1^1$ | 0         | -1   | $(\bar{N}, N)$ |

Table 1: R-charge

Here $j$ and $r$ are the spin of $SU(2)_R$ and $U(1)_R$, respectively. This gauge theory has the $\mathcal{N} = 2$ superconformal symmetry. The chiral primary operators are operators with
\[ \Delta = 2j + r/2 \] \cite{23}. Below we also use the \( Z_M \) projected \( NM \times NM \) matrices \( Z, Q^1, Q^2 \) and they are defined as follows

\[
Z = \begin{pmatrix}
Z_1 & 0 & \cdots & \cdots & 0 \\
0 & Z_2 & \cdots & \cdots & 0 \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
0 & 0 & \cdots & \cdots & Z_M
\end{pmatrix}, \quad Q = \begin{pmatrix}
0 & Q_1 & 0 & \cdots & 0 \\
0 & 0 & Q_2 & 0 & 0 \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
\vdots & \vdots & \ddots & Q_{M-1} & \vdots \\
Q_M & 0 & \cdots & \cdots & 0
\end{pmatrix}.
\] (3.23)

After we take the pp-wave limit, we have again the translation rule (2.5) and we should consider the operators which have \( \Delta \sim J \sim \sqrt{N} \) only. From the Table 1, we see that they are operators constructed from \( J Z \)'s and finite, but, arbitrary numbers of \( Q \)'s and \( \bar{Q} \)'s. Then we can naturally identify the translation rule of the gauge theory operators into the operators in the string theory:

\[
(\alpha^1_n, \alpha^{\dagger 1}_n, \alpha^{12}_n, \alpha^{\dagger 2}_n) \leftrightarrow (Q^1, \bar{Q}^1, Q^2, \bar{Q}^2).
\] (3.24)

The translation rule with respect to the other bosonic fields in the gauge theory is the same as in the \( \mathcal{N} = 4 \) case (2.6).

The light-cone energy (3.20) is rewritten in the gauge theoretic language as follows

\[
\Delta - J = \sqrt{1 + \frac{4\pi g NM(n + \delta)^2}{J^2}} = \sqrt{1 + \frac{4\pi g' N(n + \delta)^2}{J^2}},
\] (3.25)

Notice that t’ Hooft coupling again appears correctly.

Next let us consider the correspondence between string states and field theory operators in detail. In the string theory, there are an untwisted and \( M - 1 \) twisted sectors. To identify the corresponding operators we define the symbol \( P \), which acts on \( Z, Q \) and \( \bar{Q} \) such that the \( Z_M \) indices are shifted by 1. From this, we can define \( M \) projectors

\[
P_m \equiv \frac{1}{M} \sum_{j=0}^{M-1} \exp\left(\frac{2\pi imj}{M}\right) P_j.
\] (3.26)

Using the projectors, we can decompose any operator constructed from \( Z, Q \) and \( \bar{Q} \) as

\[
O_m = P_m O(Z, Q, \bar{Q}).
\] (3.27)

Then \( O_m \) is naively expected to correspond to the \( m \)-th twisted sector.

\footnote{In this paper, we only consider the single trace operators. The operators of \( \Delta - J = 2, 3, \cdots \), such as \( \bar{Z}, \partial Q, \cdots \) also are not considered since we expect such operators have a large conformal dimension in \( \mathcal{N} \to \infty \) limit as argued in \cite{3}.}
The most simple example is the following operator

\[ P_m \text{tr} \left[ (Z_i)^J \right] = \frac{1}{M} \sum_{j=0}^{M-1} \exp \left( \frac{2\pi imj}{M} \right) \text{tr} \left[ (Z_j)^J \right], \tag{3.28} \]

which will couple to the \( m \)-th twisted sector and correspond to the \( m \)-th twisted sector vacuum. This speculation can be proved exactly as follows. First note that the disk amplitude \( A \) of the \( m \)-th twisted field in closed string and the open string massless field \( Z \) is given\(^6\) by

\[ A = \text{Tr} \left[ \gamma_m \cdot Z^J \right] \cdot \langle V_m (V_Z)^J \rangle, \tag{3.29} \]

where \( V_m \) and \( V_Z \) are vertex operators of the \( m \)-th twisted closed string and the open string, respectively; \( \langle \cdots \rangle \) denotes the correlation function and the integration over moduli of world-sheet. The Chan-Paton matrix \( \gamma_m \) represents the ‘Chan-Paton factor’ for \( m \)-th twisted sector as introduced in [19, 27]. Its explicit form is the following diagonal matrix.

\[ \gamma_m = \text{diag} \left( 1, e^{\frac{2\pi im}{M}}, e^{\frac{4\pi im}{M}}, \cdots, e^{\frac{2(M-1)\pi im}{M}} \right). \tag{3.30} \]

Then the trace of Chan-Paton factor is given by \( e^{\frac{2\pi imj}{M}} \) and thus we finish the proof.

These simple operators (3.28) are chiral primary and their conformal dimensions are given by \( \Delta - J = 0 \). Note that for these states the spin of R-symmetry \( SU(2)_R \) vanishes.

In the string theory side we can identify \( O_m \) with the oscillator vacuum state \( |\text{vac}, p^- = 0, p^+\rangle_m \) in \( m \)-th twisted sector.

Next we would like to consider operators corresponding to the excited states. We cannot insert a single operator which has a non-zero \( SU(2)_R \) charge because of \( Z_M \) projection. This is consistent with the string theoretic interpretation (3.24). Note that this phenomenon is different from the \( \mathcal{N} = 4 \) case [3], where we can insert such a single operator if the ‘momentum’ vanishes \( n = 0 \). Thus let us examine more than one excitation. Then a naive guess is, for example, simply following the procedures (2.9) and (3.26)

\[ \sum_{j=0}^{M-1} \exp \left( \frac{2\pi imj}{M} \right) \times \sum_{k=0}^{J} \exp \left( \frac{2\pi ikn}{J} \right) \times \text{tr} \left[ (Z_j)^k Q'(Z_{j+1})^{J-k} Q' \right], \tag{3.31} \]

where \( Q' \) represents \( Q' \) or \( \bar{Q}' \). This is, however, incorrect because they do not reproduce the level matching condition. For instance, in \( M = 2 \) case the particular operator with \( n = 0 \)

\[ \sum_{j=0}^{1} \exp (\pi imj) \times \sum_{k=0}^{J} \text{tr} \left[ (Z_j)^k Q_j^1 (Z_{j+1})^{J-k} Q_{j+1}^1 \right]. \tag{3.32} \]

\(^6\)Here we defined \( \text{Tr} \) as the trace for a \( NM \times NM \) matrix, while \( \text{tr} \) as the trace for a \( N \times N \) matrix.
vanishes except \( m = 0 \) since the \( \text{tr}[\cdots] \) takes the same value for \( j = 0 \) and \( j = 1 \). However, we have seen that there exists the string state \( \alpha_0 \alpha_1^+ |\text{vac}, 0, p^+\rangle_{m=1} \), which satisfies the level matching condition. Moreover, we can see that the corrections to \( \Delta - J \) of order \( g \) are not reproduced by (3.31). Thus this naive definition is problematic and we should modify the identification.

Remembering the computation of previous disk amplitude (3.29) we would like to propose that the string state

\[
\prod_{i=1}^{s} (\alpha_{m_i}^+) |\text{vac}, 0, p^+\rangle_m, \tag{3.33}
\]

corresponds to the following operator instead of (3.31)

\[
\sum_{l_i=0}^{J-1} \prod_{i=1}^{s} \exp \left( 2\pi i \frac{l_i(n_i + \epsilon_i \delta)}{J} \right) \text{Tr} \left( \gamma_m Z^{k_1} Q' Z^{k_2} Q' \cdots Z^{k_s} Q' Z^{J-\sum_{i=1}^{s} k_i} \right)
= \sum_{l_i=0}^{J-1} \prod_{i=1}^{s} \exp \left( 2\pi i \frac{l_i \sum_{j=1}^{s} (n_j + \epsilon_j \delta)}{J} \right) \prod_{i=1}^{s} \exp \left( 2\pi i \frac{(l_i - l_1)(n_i + \epsilon_i \delta)}{J} \right)
\times \text{Tr} \left( \gamma_m Z^{k_1} Q' Z^{k_2} Q' \cdots Z^{k_s} Q' Z^{J-\sum_{i=1}^{s} k_i} \right), \tag{3.34}
\]

where we use the same convention as in (2.9) and \( \epsilon_i \) is a sign of \( Q' \)'s fractional level\(^7\). The operators \( Q' \) inserted in front of the \( l_i \)-th \( Z \) are equivalent to the string state (3.33) via the rule (3.24). Note that here we used the trace \( \text{Tr} \) for \( NM \times NM \) matrices and we assumed that the fields \( Z \) and \( Q' \) are \( Z_M \) projected as in (3.23). Then we can see that the level matching condition is satisfied because the last line of (3.34) depends only on \( (l_i - l_1) \). Therefore we can find the complete correspondence between the string spectrum and operators in the gauge theory.

The shift of moding \( n_i \) by \( \epsilon_i \delta \) in the above operator can be explained as follows. It should be required that the operator like (3.34) is invariant under the shift of the position \( Q' \). In particular we can shift the value of \( l_i \) by \( J \) which corresponds to the rotation of \( Q' \) in the trace. This is because we can interpret \( l_i/J \) as the world-sheet periodic coordinate \( \sigma \) in (3.15) following the general idea of [4] that the “string of \( Z \)'s” can be regarded as the physical string. If we move one of the fields \( Q^1, \bar{Q}^2 \) (or \( Q^2, \bar{Q}^1 \)) so that it crosses the matrix \( \gamma_m \), then we have the extra factor \( e^{2\pi i \delta} \) (or \( e^{-2\pi i \delta} \)). A typical example is shown below

\[
\text{Tr} \left[ \gamma_m Z^{k} \bar{Q}^1 Z^{J-k} Q^1 \right] = e^{2\pi i \delta} \text{Tr} \left[ \gamma_m Z^{J-k} Q^1 Z^{k} \bar{Q}^1 \right], \tag{3.35}
\]

\(^7\)Here we defined the values of \( \epsilon_i \) such that \( \epsilon_i = 1 \) for \( \bar{Q}^1, Q^2 \) and \( \epsilon_i = -1 \) for \( Q^1, \bar{Q}^2 \). Then \( n_i + \delta \epsilon_i \) is equal to the level in (3.21).
where we have employed the commutation relation $Q^1\gamma_m = e^{2\pi i \delta \gamma_m}Q^1$. In order to cancel this extra factor we must shift the value of $n_i$ by $\epsilon_i \delta$. Actually under the shift of $l_i$ the summation of (3.34) is invariant. In other words, the presence of the matrix $\gamma_m$ is equivalent to the existence of Wilson line in the ‘periodic direction $\sigma$’ and thus it shifts the value of momentum. In this way the quiver gauge theory operator (3.34) explicitly shows the twisted boundary condition in the string theory of the orbifolded pp-wave!

Let us examine the operator (3.34) in the explicit examples which include two hyper multiplet fields. There are four possibilities of hyper multiplets: $Q^1\bar{Q}^1$, $Q^2\bar{Q}^2$, $Q^1Q^2$ and $\bar{Q}^1\bar{Q}^2$. These states each correspond to the following four states in pp-wave string theory (see the rule (3.24))

$$\alpha_1\bar{\alpha}_1|\text{vac}\rangle, \quad \alpha_2\bar{\alpha}_2|\text{vac}\rangle, \quad \alpha_1\bar{\alpha}_2|\text{vac}\rangle, \quad \alpha_2\bar{\alpha}_1|\text{vac}\rangle.$$ (3.36)

Note that these states satisfy the level matching condition and the $Z_M$ invariance.

We can construct the dual operator in the gauge theory side by using the general formula (3.34). Then we obtain the following result in the $Q^1Q^2$ case (up to the normalization factor) after taking the trace with respect to $j=0, 1, \cdots, M-1$

$$\sum_{j=0}^{M-1} \exp(2\pi i j \delta) \times \sum_{k=0}^{J-1} \exp(2\pi i k (n - \delta)) \times \text{tr} \left[ (Z_j)^k Q_j^1 (Z_{j+1})^{J-k} Q_j^2 \right],$$ (3.37)

and similar results can be shown in the other three cases.

We can check that this operator has the correct conformal dimension in the large $N$ limit

$$\Delta - J = 2\sqrt{1 + \frac{4\pi g'N(n - \delta)^2}{J^2}} \approx 2 + \frac{4\pi g'N(n - \delta)^2}{J^2},$$ (3.38)

to the first order in the coupling $g' \sim g_{YM}^2$ as in the paper [5]. The correction proportional to $g'N/J^2$ comes from the interaction $\sim \sum_{j=0}^{J-1} (Z_j Q_j^1 \bar{Z}_j Q_j^1 + Z_{j+1} Q_{j+1}^1 \bar{Z}_j Q_j^1) + (Q^2 \bar{Q}^2 \bar{Z} \text{ term})$. We have also used the “dilute gas” approximation as in [5].

We can also generally check that the spectrum of the string theory is consistent with the quiver gauge theory result at least up to $g'$ order for the operator form (3.34)

$$\Delta - J = \sum_{i=1}^{s} \sqrt{1 + \frac{4\pi g'N(n_i + \epsilon_i \delta)^2}{J^2}} \approx s + \sum_{i=1}^{s} \frac{2\pi g'N(n_i + \epsilon_i \delta)^2}{J^2},$$ (3.39)

8 There is a subtle point in this argument for the operators which are not chiral. Here we assume the momentum independent contributions vanish if $n = m = 0$.

9 One can see that the interaction of the form $QQ\bar{Q}\bar{Q}$ does not affect our arguments in the dilute gas approximation. Then we expect this term can be ignored.
Finally we would like to mention the gauge theory dual of the string states which include the fermionic operators $S^a_n$ ($a = 1, 2, \cdots, 8$). There are four fermionic operators which are $Z_M$ invariant. They correspond to fermions in the vector multiplets of $\mathcal{N} = 2$ quiver gauge theory. The other four operators which are not $Z_M$ invariant correspond to fermions in the hyper multiplets. Both of them can be treated in the same way as $Z$ and $Q'$, respectively and thus we omit the detailed discussion.

4 General orbifolds

Here let us briefly discuss the generalization of previous results for other two dimensional orbifolds $C^2/\Gamma$. First consider non-abelian supersymmetric orbifolds which are classified by $A(=Z_M), D, E$ series [20, 27]. In these orbifolds each twisted sector is labeled by the conjugacy class $C_\beta$, $C_\beta$, ($\beta = 1, 2, \cdots, r$) of $\Gamma$. The quiver gauge theories correspond to the regular representation $\rho_{\text{reg}} = \oplus_{\alpha=1}^r n_\alpha \rho_\alpha$, where $\rho_\alpha$ ($1 \leq \alpha \leq r$) are irreducible representations of $\Gamma$ and we defined $n_\alpha \equiv \dim \rho_\alpha$. Their gauge groups are given by $G = \prod_{\alpha=1}^r U(N n_\alpha)$ and each gauge coupling is given by $\tau_\alpha = n_\alpha \tau/|\Gamma|$ ($\tau = i/g + \chi$). In order to know the coupling of fields in the gauge theory to the $C_\beta$ twisted sector we have only to replace (3.26) with

$$\frac{1}{|\Gamma|} \sum_{\alpha=1}^r \chi_\alpha(C_\beta) P_\alpha,$$

where $\chi_\alpha(g) = \text{tr}_\alpha(g)$ denotes the character of an element of $g \in \Gamma$ in $\rho_\alpha$ representation. The symbol $P_\alpha$ denotes the projection onto the gauge group $U(N n_\alpha)$. All other arguments (e.g.,(3.34)) in the section three can also be generalized for $D$ and $E$ cases.

It is also interesting to consider non-supersymmetric orbifolds. For example, let us consider the $Z_M$ orbifold defined by

$$\phi_1 \to e^{2\pi i M} \phi_1, \quad \phi_2 \to e^{-2\pi i L} \phi_2,$$

where $L$ is an odd integer and except for the cases $L = \pm 1$ the supersymmetry is completely broken. This orbifold was recently discussed in the context of closed string tachyon condensation [28]. Then we can speculate the same identification (3.24) in the untwisted sector. Here we should regard scalar fields $Q^1$ and $Q^2$ as $(Q^1_{j,j+1}, (Q^2_{j+L,j})$ instead of $(Q^1_{j}), j+1, (Q^2_{j+L,j})$ instead of $(Q^1_{j}), j+1, (Q^2_{j}), j$), where we have written the indices of Chan-Paton matrices explicitly. The quantization of GS string on this nonsupersymmetric background is also the same as in section 3.1. In twisted sectors, however, the spectrum of string is slightly difficult to analyze because of the ambiguity of zero energy. In any case it
will be an intriguing fact that we can find string states in untwisted sector whose light-cone energy is independent of the coupling $g$. Thus there seem to exist the operators whose conformal dimensions are fixed as $\Delta - J = 0, 1, 2, \ldots$ in the large $N$ limit of the non-supersymmetric gauge theory if we believe the AdS/CFT correspondence in such a pp-wave limit.

5 Conclusions

In this paper we investigated an extension of the AdS/CFT correspondence in the limit of the orbifolded pp-wave background. We examined both the spectrum of states in the orbifolded Green-Schwarz string and the operators in the gauge theory side. The results show that the duality between string theory and $\mathcal{N} = 4$ super Yang-Mills theory discussed in [3] holds for less supersymmetric case ($\mathcal{N} = 2$ quiver gauge theory). We found an interesting interpretation of the twisted boundary condition in the orbifold theory from the viewpoint of the quiver gauge theory. We also discussed the similar issue in more general orbifolds and found that some parts of the results can be applied to non-supersymmetric orbifolds. It will be also interesting to analyze the pp-wave limit of D3-branes on the orbifolds $\mathbb{C}^3/\Gamma$, which will lead to $\mathcal{N} = 1$ quiver gauge theory (for some previous discussions see [22]).
